| A. C. S. | ALBERT CHARLES SEWARD, M.A., F.R.S.  
Professor of Botany in the University of Cambridge. Hon. Fellow of Emmanuel College, Cambridge. President of the Yorkshire Naturalists' Union, 1910. |
| A. F. P. | ALBERT FREDERICK FOLLARD, M.A., F.R.HIST.S.  
| A. G. D. | ARTHUR GEORGE DOUTHY, M.A., LITT.D., C.M.G.  
| A. G. H. | ALBERT GEORGE HADCOCK.  
| A. Ha. | ADOLF HARNACK.  
See the biographical article: HARNACK, ADOLF. |
| A. J. L. | ANDREW JACKSON LAMOUREUX.  
Librarian, College of Agriculture, Cornell University. Formerly Editor of the Rio News, Rio de Janeiro. |
| A. Lu. | ACHILLE LUCHAIRE.  
See the biographical article: LUCHAIRE, DENIS J. ACHILLE. |
| A. Ma. | ALEXANDER MACALISTER, M.A., M.D., LL.D., D.Sc., F.R.S., F.S.A.  
Professor of Anatomy in the University of Cambridge, and Fellow of St John's College. Author of Text-Book of Human Anatomy; &c. |
| A. M. Cl. | AGNES MURIEL CLAY (Mrs Wilde).  
Formerly Resident Tutor of Lady Margaret Hall, Oxford. Joint-author of Sources of Roman History, 133–70 B.C. |
| A. N. | ALFRED NEWTON, F.R.S.  
See the biographical article: NEWTON, ALFRED. |
| A. P. H. | ALFRED PETER HILLIER, M.D., M.P.  
| A. S.-P. | ANTHYME ST PAUL.  
Author of Histoire Monumentale de la France. |
| A. S. Wo. | ARTHUR SMITH WOODWARD, LL.D., F.R.S.  
Keeper of Geology, Natural History Museum, South Kensington. Secretary of the Geological Society, London. |
| A. Wa. | ARTHUR WAUGH, M.A.  
| A. W. H.* | ARTHUR WILLIAM HOLLAND.  
Formerly Scholar of St John's College, Oxford. Bacon Scholar of Gray's Inn, 1900. |

¹A complete list, showing all individual contributors, appears in the final volume.
A. W. R
Alexander Wood Renton, M.A., LL.B.

A. W. W
Adolphus William Ward, Litt.D., LL.D.
See the biographical article: Ward, A. W.

B. R
Adviser on Petroleum to the Admiralty, Home Office, India Office, Corporation of London, and Port of London Authority. President of the Society of Chemical Industry. Member of the Council of the Chemical Society. Member of Council of Institute of Chemistry. Author of "Cantor" Lectures on Petroleum; Petroleum and its Products; Chemical Technology; &c.

C. E.
Charles Everett, M.A., F.C.S., F.G.S., F.R.A.S.
Formerly Scholar of Magdalen College, Oxford.

C. F. A
Charles Francis Atkinson.
Formerly Scholar of Queen's College, Oxford. Captain, 1st City of London (Roj I. Fusiliers). Author of The Wilderness and Cold Harbour.

C. H. Ha
Carlton Huntley Hayes, A.M., Ph.D.
Assistant Professor of History in Columbia University, New York City. Member of the American Historical Association.

C. L. K
Assistant Secretary to the Board of Education. Author of Life of Henry V. Editor of Chronicles of London; and Stow's Survey of London.

C. R
Clement Reid, F.R.S., F.L.S., F.G.S.

C. R. B
Professor of Modern History in the University of Birmingham. Formerly Fellow of Merton College, Oxford, and University Lecturer in the History of Geography. Lothian Prizeeman, Oxford, 1889. Lowell Lecturer, Boston, 1908. Author of Henry the Navigator; The Dawn of Modern Geography; &c.

C. We
Cecil Weatherly.
Formerly Scholar of Queen's College, Oxford. Barrister-at-Law.

D. B
Henri de Blowitz.
See the biographical article: Blowitz, H. G. S. A. De.

D. C
Dugald Clerk, M.Inst.C.E., F.R.S.
Director of the National Gas Engine Co., Ltd. Inventor of the Clerk Cycle Gas Engine.

D. F. T
Donald Francis Tovey.
Author of Essays in Musical Analysis; comprising The Classical Concerto, The Goldberg Variations, and analyses of many other classical works.

D. G. H
David George Hogarth, M.A.

D. H
David Hannay.
Formerly British Vice-Consul at Barcelona. Author of Short History of the Royal Navy; Life of Emilio Castellar; &c.

D. H. S
Duxfield Henry Scott, M.A., Ph.D., LL.D., F.R.S.
President of the Linnean Society. Author of Structural Botany; Studies in Fossil Botany; &c.

D. J. H
Professor of Pathology, Aberdeen University, 1882-1907. Author of Text-Book of Pathology; &c.

E. A. F
Edward Augustus Freeman, LL.D., D.C.L.
See the biographical article: Freeman, E. A.

E. B. T
Edward Burnett Tylor, D.C.L., LL.D.
See the biographical article: Tylor, Edward Burnett.

E. C. B

E. C. Q
Edmund Crosby Quiggin, M.A.
Fellow, Lecturer in Modern Languages, and Monro Lecturer in Celtic, Gonville and Caius College, Cambridge.

E. G
Edmund Gosse, LL.D.
See the biographical article: Gosse, EDMUND.

E. Gr
Ernest Arthur Gardner, M.A.
See the biographical article: Gardner, Percy.

ODE (Gr. ὕδη, from ἀδεία, to sing), a form of stately and elaborate lyrical verse. As its name shows, the original signification of an ode was a chant, a poem arranged to be sung to an instrumental accompaniment. There were two great divisions of the Greek *melos* or song; the one the personal utterance of the poet, the other, as Professor G. G. Murray says, "the choric song of his band of trained dancers." Each of these culminated in what have been called odes, but the former, in the hands of Alcaeus, Anacreon and Sappho, came closer to what modern criticism knows as lyric, pure and simple. On the other hand, the choir-song, in which the poet spoke for himself, but always supported, or interpreted, by a chorus, led up to what is now known as ode proper. It was Alcaeus, as is supposed, who first gave to his poems a strophic arrangement, and the strophe has come to be essential to an ode. Stesichorus, Ibycus and Simonides of Ceos led the way to the two great masters of ode among the ancients, Pindar and Bacchylides. The form and verse-arrangement of Pindar's great lyrics have regulated the type of the heroic ode. It is now perceived that they are consciously composed in very elaborate measures, and that each is the result of a separate act of creative ingenuity, but each preserving an absolute consistency of form. So far from being, as critics down to Cowley and Boileau, and indeed to the time of August Böckh, supposed, utterly licentious in their irregularity, they are more like the *canzon* and *sirventes* of the medieval troubadours than any modern verse. The Latins themselves seem to have lost the secret of these complicated harmonies, and they made no serious attempt to imitate the odes of Pindar and Bacchylides. It is probable that the Greek odes gradually lost their musical character; they were accompanied on the flute, and then declared without any music at all. The ode, as it was practised by the Romans, returned to the personally lyrical form of the Lesbian lyrists. This was exemplified, in the most exquisite way, by Horace and Catullus; the former imitated, and even translated, Alcaeus and Anacreon, the latter was directly inspired by Sappho.

The earliest modern writer to perceive the value of the antique ode was Ronsard, who attempted with as much energy as he could exercise to recover the fire and volume of Pindar; his principal experiments date from 1550 to 1552. The poets of the Pleiad recognized in the ode one of the forms of verse with which French prosody should be enriched, but they went too far, and in their use of Greek words crudely introduced, and in their quantitative experiments, they offended the genius of the French language. The ode, however, died in France almost as rapidly as it had come to life; it hardly survived the 16th century, and neither the examples of J. B. Rousseau nor of Saint-Amant nor of Malherbe possessed much poetic life. Early in the 19th century the form was resumed, and we have the *Odes* composed between 1817 and 1824 by Victor Hugo, the philosophical and religious odes of Lamartine, those of Victor de Laprade (collected in 1844), and the brilliant *Odes funambulesques* of Théodore de Banville (1857).

The earliest odes in the English language, using the word in its strict form, were the magnificent *Epithalamium* and *Prothalamium* of Spenser. Ben Jonson introduced a kind of elaborate lyric, in stanzas of rhymed irregular verse, to which he gave the name of ode; and some of his disciples, in particular Randolph, Cartwright and Herrick, followed him. The great "Hymn on the Morning of Christ's Nativity," begun by Milton in 1629, may be considered an ode, and his lyrics "On Time" and "At a Solemn Music" may claim to belong to the same category. But it was Cowley who introduced into English poetry the ode consciously built up, on a solemn theme and as definitely as possible on the ancient Greek pattern. Being in exile in France about 1645, and at a place where the only book was the text of Pindar, Cowley set himself to study and to imitate the *Epiktia*. He conceived, he says, that this was "the noblest and the highest kind of writing in verse," but he was no more perspicacious than others in observing what the rules were which Pindar had followed. He supposed the Greek poet to be carried away on a storm of heroic emotion, in which all the discipline of prosody was disregarded. In 1656 Cowley published his Pindaric odes, in which he had not even regarded the elements of the Greek structure, with strophe, antistrophe and epode. His idea of an ode, which he impressed with such success upon the British nation that it has never been entirely removed, was of a lofty and tempestuous piece of indefinite poetry, conducted without sail or oar in whatever direction the enthusiasm of the poet chose to take it. These shapeless pieces became very popular after the Restoration, and enjoyed the sanction of Dryden in three or four irregular odes which are the best of their kind in the English language. Prior, in a humorous ode on the taking of Namur (1695), imitated the French type of this poem, as cultivated by Boileau. In 1705 Congreve published a *Discourse on the Pindaric Ode*, in which many of the critical errors of Cowley were corrected; and Congreve wrote odes, in strophe, antistrophe and epode,
which were the earliest of their kind in English; unhappily they were not very poetical. He was imitated by Ambrose Philips, but then the tide of Cowley-Pindarism rose again and swept the reform away. The attempts of Gilbert West (1623-1756) to explain the prosody of Pindar (1740) inspired Gray to write his "Progress of Poesy" (1754) and "The Bard" (1756). Collins, meanwhile, had in 1747 published a collection of odes devised in the Aeolian or Lesbian manner. The odes of Mason and Akenside were more correctly Pindaric, but frigid and formal. The odes of Wordsworth, Coleridge and Tennyson are entirely irregular. Shelley desired to revive the pure manner of the Greeks, but he understood the principle of the form so little that he began his noble "Ode to Naples" with two epodes, passed on to two strophes, and then indulged in four successive antistrophes. Coventry Patmore, in 1868, printed a volume of Odes, which he afterwards enlarged; these were irregularly built up on a musical system, the exact consistency of which is not always apparent. Finally Swinburne, although some of his odes, like those of Keats, are really elaborate lyrics, written in a succession of stanzas identical in form, has cultivated the Greek form also, and some of his political odes follow very closely the type of Bacchylides and Pindar.

ODENKIRCHEN—ODER

ODENKIRCHEN, a town of Germany, in the Prussian Rhine province, 21 m. by rail S.W. of Düsseldorf, and at the junction of lines to Munich, Gladbach and Stolberg. Pop. (1905) 16,808. It has a Roman Catholic church, an Evangelical one, a synagogue and several schools. Its principal industries are spinning, weaving, tanning and dyeing. Odenkirchen became a town in 1826. See Wiedemann, Geschichte der ehemaligen Herrschaft und des Hauses Odenkirchen (Odenkirchen, 1879).

ODENSE, a city of Denmark, the chief town of the amt (county) of its name, which forms the northern part of the island of Funen (Fyen). Pop. (1901) 40,138. The city lies 4 m. from Odense Fjord on the Odense Aa, the main portion on the north side of the stream, and the industrial Alban quartern on the south side. It has a station on the railway route between Copenhagen and Jutland and Schleswig-Holstein via Korsør. A canal, 153 ft. deep, gives access to the town from the fjord. St Canute's cathedral, formerly connected with the great Benedictine monastery of the same name, is one of the largest and finest buildings of its kind in Denmark. It is constructed of brick in a pure Gothic style. Originally dating from 1057-1095, it was rebuilt in the 13th century. Under the altar lies Canute (Knut), the 11th king of Denmark, who intended to dispute with William of Normandy the possession of England, but was slain in an insurrection at Odense in 1086; Kings John and Christian II. are also buried within the walls. Our Lady's church, built in the 12th century and restored in 1851-1852 and again in 1864, contains a carved altarpiece (16th century) by Claus Berg of Lübeck. Odense Castle was erected by Frederick IV., who died there in 1730. In Albani are tanneries, iron-foundries and machine-shops. Exports, mostly agricultural produce (butter, bacon, eggs); imports, iron, petroleum, coal, yarn and timber.

Odense, or Odinse, originally Odinsoe, i.e. Odin's island, is one of the oldest cities of Denmark. St Canute's shrine was a great resort of pilgrims throughout the middle ages. In the 16th century the town was the meeting-place of several parliaments, and down to 1805 it was the seat of the provincial assembly of Funen.

ODENWALD, a wooded mountainous region of Germany, almost entirely in the grand duchy of Hesse, with small portions in Bavaria and Baden. It stretches between the Neckar and the Main and has some 50 m. long by 20 to 30 broad. Its highest points are the Katzenbuckel (2057 ft.), the Neunkircher Höhe (1985 ft.) and the Krähhberg (1965 ft.). The wooded heights overlooking the Bergstrasse are studded with castles and medieval ruins, some of which are associated with some of the most memorable adventures of German tradition. Among them are Rodenstein, the reputed home of the wild huntsman, and near Graselbenbach, the spot where Siegfried of the Nibelungenlied is said to have been slain.

See F. Montanus, Der Odenwald (Mainz, 1884); T. Lorenzten, Der Odenwald in Wort und Bild (Stuttgart, 1903); G. Volk, Der Odenwald und seine Nachbargebiete (Stuttgart, 1900), and Windhau, 'Führer durch den Odenwald (Darmstadt, 1903).

ODER (Lat. Via duv; Slavonic, Vjodr), a river of Germany, rises in Austria on the Odergebirge in the Moravian tableland at a height of 19.5 ft. above the sea, and 14 m. to the east of Olmütz. From its source to its mouth in the Baltic it has a total length of 560 m., of which 480 m. are navigable for barges, and it drains an area of 43,300 sq. m. The first 45 m. of its course lie within Moravia; for the next 15 m. it forms the frontier between Prussian and Austrian Silesia, while the remaining 500 m. belong to Prussia, where it traverses the provinces of Silesia, Brandenburg and Pomerania. It flows at first towards the south-east, but on quitting Austria turns towards the north-west, maintaining this direction as far as Frankfort-on-Oder, beyond which its general course is nearly due north. As far as the frontier the Oder flows through a well-defined valley, but, after passing through the gap between the Moravian mountains, and the Carpathians and entering the Silesian plain, its valley is wide and shallow and its banks generally low. In its lower course it is divided into numerous branches, forming many islands. The main channel follows the left side of the valley and finally expands into the Pommersches, or Stettiner Haff, which is connected with the sea by three arms, the Peene, the Swine and the Dievenow, forming the islands of Usedom and Wollin. The Swine, in the middle, is the main channel for navigation. The chief tributaries of the Oder on the left bank are the Oppa, Glater Neisse, Katzbach, Bober and Lausitzer Neisse; on the right bank the Malapan, Bartsch and Warthe. Of these the only one of importance for navigation is the Warthe, which through the Netze is brought into communication with the Vistula. The Oder is also connected by canals with the Havel and the Spree. The most important towns on its banks are Ratibor, Oppeln, Brieg, Breslau, Glogau, Frankfort, Cœstrin and Stettin, with the seaport of Swinemünde at its mouth. Glogau, Cœstrin and Swinemünde are strongly fortified.

The earliest important undertaking with a view of improving the waterway was due to the initiative of Frederick the Great, who recommended the diversion of the river into a new and straight channel in the swampy tract of land known as the Oderbruch, near Cœstrin. The work was carried out in the years 1747-1753, a large tract of marshland being brought under cultivation, a considerable detour cut off, and the main stream successfully confined to the canal, 12 m. in length, which is known as the New Oder. The river at present begins to be navigable for barges at Ratibor, where it is about 100 ft. wide, and for larger vessels at Breslau, and great exertions are made by the government to deepen and keep open the channel, which still shows a strong tendency to choke itself with sand in certain places. The alterations made of late years consist of three systems of works:—(1) The canalization of the main stream (4 m.) at Breslau, and from the confluence of the Glater Neisse to the mouth of the Klodnitz canal, a distance of over 50 m. These engineering works were completed in 1896. (2) In 1887-1891 the Oder-Spree canal was made to connect the two rivers named. The canal leaves the Oder at Fürstenberg (132 m. above its mouth) at an altitude of 93 ft., and after 15 m. enters the Friedrich-Wilhelm canal (134 ft.). After coinciding with this for 7 m., it makes another cut of 5 m. to the Spree at Fürstenwalde (126 ft.). Then it follows the Spree for 12 m., and at Gross Tränke (121 ft.) passes out and goes to Lake Sédin (106 ft.), 15 m. (3) The deepening and regulation of the mouth and lower course of the stream, consisting of the Kaiserfahrt, 3 m. long, affording a waterway between the Stettiner Haff and the river Swine for the largest ocean-going vessels; a new branch, 41 m. long, from Vetschau to the Stettiner Haff to Wollin Island; the Parnitz-Dunzig and Dunzig-Oder canals, together 1 m. long,
ODERBERG—ODESSA

3

constituting the immediate approach to Stettin. Vessels drawing 24 ft. are now able to go right up to Stettin. In 1905 a project was sanctioned for improving the communication between Berlin and Stettin by widening and deepening the lower course of the river and then connecting this by a canal with Berlin. Another project, born at the same time, is one for the canalization of the upper course of the Oder. About 4,000,000 tons of merchandise pass through Breslau (up and down) on the Oder in the year.

See Der Oderstrom, sein Stromgebiet und seine wichtigsten Nebenflüsse; hydrographische, wasserwirtschaftliche und wasserrechtliche Darstellung (Berlin, 1896).

ODERBERG, a town of Germany, in the Prussian province of Brandenburg, on the Alte Oder, 2 m. from Brlitz, a station 44 m. N.W. from Frankfort-on-Oder, by the railway to Angermünde. Pop. (1905) 4,019. It has a fine Gothic church, dedicated to St Nicholas, and the ruins of an ancient castle, called Bärenkasten. Oderberg is an important emporium for the Russian timber trade.

ODESCALCHI-ERBA, the name of a Roman princely family of great antiquity. They are supposed to be descended from Enrico Erba, imperial vicar in Milan in 1165; Alessandro Erba married Lucrezia Odescalchi, sister of Pope Innocent IX, in 1700, is believed to have been descended from Giorgio Odescalchi (floruit at Como in 1290). The title of prince of the Holy Roman Empire was conferred on Alessandro in 1714, and that of duke of Sycium in Hungary in 1714, with the qualification of "serene highness." The head of the family now bears the titles of Fürst Odesschali, duke of Sycium, prince of Bassano, &c., and he is an hereditary magnate of Hungary and a grandee of Spain; the family, which is one of the most important in Italy, owns the Palazzo Odeshchali in Rome, the magnificent castle of Bracciano, besides large estates in Italy and Hungary.

See a. von Reumont, Geschichte der Stadt Rom (Berlin, 1868), and the Almanach de Gotha.

ODESSA, one of the most important seaports of Russia, ranking by its population and foreign trade after St Petersburg; Moscow and Warsaw. It is situated in 46° 28' N. and 30° 44' E., on the southern shore of a semi-circular bay, at the north-west angle of the Black Sea, and is by rail 1017 m. S.S.W. from Moscow and 610 S. from Kiev. Odessa is the seaport for the basins of two great rivers of Russia, the Dnieper, with its tributary the Bug, and the Dniester (20 m. to S.). The entrances to the mouths of both these offering many difficulties for navigation, trade has from the remotest antiquity selected this spot, which is situated half-way between the two estuaries, while the level surface of the neighbouring steppe allows easy communication with the lower parts of both rivers. The bay of Odessa, which has an area of 14 sq. m. and a depth of 30 ft. with a soft bottom, is a dangerous anchorage on account of its exposure to easterly winds. But inside it are six harbours—the quarantine harbour, new harbour, coal harbour and "practical" harbour, the first and last, on the S. and N., respectively, protected by mole, and the two middle harbours by a breakwater. Besides these, there are the harbour of the principal shipping company, the Russian Company for Navigation and Commerce, and the petroleum harbour. The harbours freeze for a few days in winter, as also does the bay occasionally, navigation being interrupted every year for an average of sixteen days; though this is materially shortened by the use of an ice-breaker. Odessa experiences the influence of the continental climate of the neighbouring steppes; its winters are cold (the average temperature for January being 23° F., and the isotherm for the entire season that of Königsberg), its summers are hot (72°-8° in July), and the yearly average temperature is 48°. The rainfall is scanty (14 in. per annum). The city is built on a terrace 100 to 155 ft. in height, which descends by steep crags to the sea, and on the other side is continuous with the level of the "black earth" steppe. Catacombs, whence sandstone for building has been taken, extend underneath the town and suburbs, without some danger to the buildings.

The general aspect of Odessa is that of a wealthy west-European city. Its chief embodiment, the Nikolai boulevard, bordered with tall and handsome houses, forms a fine promenade. The central square is adorned with a statue of Armand, due de Richelieu (1826), who was governor of Odessa in 1832-1834. A little back from the sea stands a fine bronze statue of Catherine II. (1900). A magnificent flight of nearly 200 granite steps leads from the Richelieu monument down to the harbours. The central parts of the city have broad streets and squares, bordered with fine buildings and mansions in the Italian style, and with good shops. The cathedral, founded in 1704 and finished in 1809, and thoroughly restored in 1903, can accommodate 5000 persons; it contains the tomb of Count Michael Vorontsov, governor-general from 1823 to 1854, who contributed much towards the development and embellishment of the city. The "Palais Royal," with its parterre and fountains, and the spacious public park are fine pleasure-grounds, whilst in the ravines that lead down to the sea cluster the houses of the poorer classes. The shore is occupied by immense granaries, some of which look like palaces, and large storehouses take up a broad space in the immediate vicinity. Odessa consists (i.) of the city proper, containing the old fort (now a quarantine establishment) and surrounded by a boulevard, where was formerly the fort marching the limits of the free port; (ii.) of the suburbs Novaya and Perekop, extending northward along the lower shore of the bay; and (iii.) of Moldavanka to the south-west. The city, being in a treeless region, is proud of the avenues of trees that line several of its streets and of its parks, especially of the Alexander Park, with a statue of Alexander II. (1891), and of the summer resorts of Fontaine, Arcadia and Langeron along the bay. Odessa is rising in repute as a summer sea-bathing resort, and its mud-baths (from the mud of the limans or lagoons) are considered to be efficacious in cases of rheumatism, gout, nervous affections and skin diseases. The German colonies Liebenthal and Lustdorf are bathing-places.

Odessa is the real capital, intellectual and commercial, of so-called Novorossia, or New Russia, which includes the governments of Bessarabia and Kherson. It is the see of an archbishop of the Orthodox Greek Church, and the headquarters of the VIII. army corps, and constitutes an independent "municipal district" or retenosta, which covers 195 sq. m. and includes a dozen villages, some of which have 2000 to 3000 inhabitants each. It is also the chief town of the Novorossian (New Russian) educational district, and has a university, which replaced the Richelieu Lyceum in 1865, and now has over 1700 students.

In 1705 the town had only 2250 inhabitants; in 1814, twenty years after its foundation, it had 25,000. The population has steadily increased from 100,000 in 1830, 185,000 in 1873, 225,000 in 1884, to 449,673 in 1900. The great majority of inhabitants are Great Russians and Little Russians; but there are also large numbers of Jews (133,000, exclusive of Karaites), as well as of Italians, Greeks, Germans and French (to which nationalities the chief merchants belong), as also of Rumanians, Servians, Bulgarians, Tatars, Armenians, Lazis, Georgians. A numerous floating population of labourers, attracted at certain periods by pressing work in the port, and afterwards left unemployed owing to the enormous fluctuations in the corn trade, is one of the features of Odessa. It is calculated that there are no less than 35,000 people living from hand to mouth in the worst misery, partly in the extensive catacombs beneath the city.

The leading occupations are connected with exporting, shipping and manufactures. The industrial development has been rather slow: sugar-refineries, tea-packing, oil-mills, tanneries, steam flour-mills, iron and mechanical works, factories of jute sacks, chemical works, tin-plate works, paper-factories are the chief. Commercially the city is the chief seaport of Russia for exports, which in favourable years are twice as high as those of St Petersburg, while as regards the value of the imports Odessa is second only to the northern capital. The total returns amount to 16 to 20 millions sterling a year, representing about one-ninth of the entire Russian foreign trade, and 14% if the coast trade be included as well.
exports are valued at 10 to 11 millions sterling annually, and the imports at 6 to 9 millions sterling, about 81% of all the imports into Russia. Grain, and especially wheat, is the chief article of export. The chief imports are raw cotton, iron, agricultural machinery, coal, chemicals, jute, copra and lead. A new and spacious harbour, especially for the petroleum trade, was constructed in 1890-1900.

History.—The bay of Odessa was colonized by Greeks at a very early period, and their ports—Istrianorum Portus and Isicorum Portus—on the shores of the bay, and Odessus at the mouth of the Tiligul—carried on a lively trade with the neighboring steps. These towns disappeared in the 3rd and 4th centuries, and for ten centuries no settlements in these tracts are mentioned. In the 14th century this region belonged to the Lithuanians, and in 1366 Olgerd, prince of Lithuania, defeated in battle three Tartar chiefs, one of whom, Khazi Bey or Bey, had recently founded, at the place now occupied by Odessa, a fort which received his name. The Lithuanians, and subsequently the Poles, kept the country under their dominion until the 17th century, when it was seized by the Tartars, who still permitted, however, the Lithuanians to gather salt in the neighboring lakes. Later on the Turks left a garrison here, and founded in 1764 the fortress Yani-dunya. In 1780 the Russians, under the French captain de Ribas, took the fortress by assault. In 1791 Khazi-bey and the Ochakov region were ceded to Russia. De Ribas and the French engineer Voland were entrusted in 1794 with the erection of a town and the construction of a port at Khazi-bey. In 1803 Odessa became the chief town of a separate municipal district or capitancy, the first town being Armand, du de Richelieu, who did very much for the development of the young city and its improvement as a seaport. In 1824 Odessa became the seat of the governors-general of Novorossia and Bessarabia. In 1866 it was brought into railway connexion with Kiev and Kharkov via Balta, and with Jassy in Rumelia. In 1854 it was unsuccessfully attacked by the Anglo-Russian fleet, and in 1876-1877 the Turks, and also the Russians, under the command of Prince Ribas, also undertook the siege. In 1906 the city was the scene of violent revolutionary disorders, marked by a naval insurrection.

ODEUM (Gr. Odéion), the name given to a concert hall in ancient Greece. In a general way its construction was similar to that of a theatre, but it was only a quarter of the size and was provided with a roof for acoustical purposes, a characteristic difference. The oldest known Odeum in Greece was the Skias at Sparta, so called from its resemblance to the top of a parasol, said to have been erected by Theodorus of Samos (600 B.C.); in Athens an Odeum near the spring Eanacreus on the Ilissus was referred to the age of Peisistratus, and appears to have been rebuilt or restored by Lycurgus (c. 350 B.C.). This is probably the building which, according to Aristophanes (Wasps, 1109), was used for judicial purposes, for the distribution of corn, and even for the billeting of soldiers. The building which served as a model for later similar constructions was the Odeum of Pergamum (completed c. 445) on the south-eastern slope of the rock of the Acropolis, whose conical roof, a supposed imitation of the tent of Xerxes, was made of the mats of captured Persian ships. It was destroyed by Aristion, the so-called tyrant of Athens, at the time of the rising against Sulla (87), and rebuilt by Ario- barzanes II., king of Cappadocia (Appian, Mithrid. 38). The most magnificent example of its kind, however, was the Odeum which built on the south-west cliff of the Acropolis at Athens about A.D. 1600 by the wealthy sophist and rhetorician Herodes Atticus in memory of his wife, considerable remains of which are still to be seen. It had accommodation for 8000 persons, and the ceiling was constructed of beautifully carved beams of cedar wood, probably with an open space in the centre to admit the light. It was also profusely decorated with pictures and other works of art. Similar buildings also existed in other parts of Greece, at Corinth, also the gift of Herodes Atticus; at Patrae, where there was a famous statue of Apollo; at Smyrna, Tralles, and other towns in Asia Minor. The first Odeum in Rome was built by Domitian, a second by Trajan.

ODILIENBERG, or Ottilienberg (called Allions in the 8th century), a peak of the Voges Mountains in Germany, in the imperial province of Alsace-Lorraine, immediately W. of the town of Barr. Its crest (2500 ft.) is surmounted by the ruins of the ancient Roman wall, the Heidenmauer, and by the convent and church of St Odilia, or Ottilia, the patron saint of Alsace, whose remains rest within. It is thus the object of frequent pilgrimages. The convent is said to have been founded by Duke Etichio I., in honour of his daughter St Odilia, about the end of the 7th century, and it is certain that it existed at the time of Charlemagne. Destroyed during the wars of the middle ages, it was rebuilt by the Premonstrants at the beginning of the 17th century, and was acquired later by the bishop of Strasbourg, who restored the building and the adjoining church, in 1853. Since 1899 the convent has contained a museum of antiquities.

See Reinhard, Le Mont Ste Odile (Strasbourg, 1888); Pfeister, Le Dernier Oden (Hannau, 1892); and R. Forrer, Der Odilienberg (Strasbourg, 1899).

ODIN, or Öthin (O. Norse Ótin), the chief god of the Northern pantheon. He is represented as an old man with one eye. Frigg is his wife, and several of the gods, including Thor and Balder, are his sons. He is also said to have been the father of several legendary kings, and more than one princely family claimed descent from him. His exploits and adventures form the theme of a number of the Edda poems, and also of several stories in the prose Edda. In all these stories his character is distinguished rather by wisdom and cunning than by martial prowess, and reference is very frequently made to his skill in poetry and magic. In Ynglings Saga he is represented as reigning in Sweden, where he established laws for his people. In notices relating to religious observances Odin appears chiefly as the giver of victory or as the god of the dead. He is frequently introduced in legendary sagas, generally in disguise, imparting secret instructions to his favorites or presenting them with weapons by which victory is assured. In return he receives the souls of the slain who in his palace, Valhalla (q.v.), live a life of fighting and feasting, similar to that which has been their desire on earth. Human sacrifices were very frequently offered to Odin, especially prisoners taken in battle. The common method of sacrifice was by hanging the victim on a tree; and in the poem Hvisorðr the god himself is represented as sacrificed in this way. The worship of Odin seems to have prevailed chiefly, if not solely, in military circles, i.e. among princely families and the retinues of warriors attached to them. It is probable, however, that the worship of Odin was once common to most of the Teutonic peoples. To the Anglo-Saxons he was known as Woden (q.v.) and to the Germans as Wodan (Wutan), which are the regular forms of the same name in those languages. It is largely owing to the peculiar character of this god and the prevalent position which he held in the mythology of the north presents so striking a contrast to that of Greece.

See Teutonic Peoples, ad fin.; and Woden.

ODO, or Eudes (d. c. 736), king, or duke, of Aquitaine, obtained this dignity about 715, and his territory included the southwestern part of Gaul from the Loire to the Pyrenees. In 718 he appears as the ally of Chilperic II., king of Neustria, who was fighting against the Austrasian mayor of the palace, Charles Martel; but after the defeat of Chilperic at Soissons in 718 he probably made peace with Charles by surrendering to him the Neustrian king and his treasures. Odo was also obliged to fight the Saracens who invaded the southern part of his kingdom, and inflict a severe defeat upon them at Toulouse in 721. When, however, he was again attacked by Charles Martel, the Saracens renewed their ravages, and Odo was defeated near Bordeaux; he was compelled to crave protection from Charles, who took up this struggle and gained his momentous victory at Poitiers in 732. In 735 the king abdicated, and was succeeded by his son Hunold.

ODE, or Eudes (d. 898), king of the Franks, was a son of Robert the Strong, count of Anjou (d. 866), and is sometimes referred to as duke of France and also as count of Paris. For his skill and bravery in resisting the attacks of the Normans
ODO OF BAYEUX—ODOACER

Odo was chosen king by the western Franks when the emperor Charles the Fat was deposed in 887, and was crowned at Compéïgne in February 888. He continued to fight against the Normans, whom he defeated at Montfaucon and elsewhere, but was soon involved in a struggle with some powerful nobles, who supported the claim of Charles, afterwards King Charles III, to the Frankish kingdom. To gain prestige and support Odo owned himself a vassal of the German king, Arnulf, but in 894 Arnulf declared for Charles. Eventually, after a struggle which lasted for three years, Odo was compelled to come to terms with his rival, and to surrender to him a district north of the Seine. He died at La Fère on the 1st of January 898.

ODO 1 OF BAYEUX (c. 1036-1097), Norman bishop and English earl, was a younger brother of William the Conqueror, from whom he received, while still a youth, the see of Bayeux (1049). But his active career was that of a warrior and statesman. He found ships for the invasion of England and fought in person at Senlac; in 1067 he became earl of Kent, and for some years he was a trusted royal minister. At times he acted as viceroy in William's absence; at times he led the royal forces to chastise rebellions. But in 1083 he was suddenly disgraced and imprisoned for having planned a military expedition to Italy. In 1084 he was returned to power to maintain order. It is more probably he thought of serving as a papal condottiere against the emperor Henry IV. The Conqueror, when on his death-bed, reluctantly permitted Odo's release (1087). The bishop returned to his earldom and soon organized a rebellion with the object of handing over England to his eldest nephew, Duke Robert. William Rufus, to the disgust of his supporters, permitted Odo to leave the kingdom after the collapse of this design (1088), and henceforward Odo was the right-hand man of Robert in Normandy. He took part in the agitation for the First Crusade, and started in the duke's company for Palestine, but died on the way, at Palermo (February 1097). Little good is recorded of Odo. His vast wealth was gained by extortion and robbery. His ambitions were boundless and his morals lax. But he was a patron of learning and, like most prelates of his age, a great architect. He rebuilt the cathedral of his see, and may perhaps have commissioned the unknown artist of the celebrated Bayeux tapestry.

See the authorities cited for WILLIAM I. and WILLIAM II., the biographers of William the Conqueror: Mathilda Comitissa, i. 353-360; H. Wharton, Anglia Sacra, i. 334-339 (1891); and F. R. Fewkes, The Bayeux Tapestry (London, 1898). (H. W. C. D.)

ODOACER, or ODOWACAR (c. 434-493), the first barbarian ruler of Italy on the downfall of the Western empire, was born in the district bordering on the middle Danube about the year 434. In this district the once rich and fertile provinces of Noricum and Pannonia were being torn piecemeal from the Roman empire by a crowd of German tribes, among whom we discern four, who seem to have hovered over the Danube from Passau to Pest, namely, the Rugi, Scyri, Turcilingi and Heruli. With all of these Odoacer was connected by his subsequent career, and all seem, more or less, to have claimed him as belonging to their stock; though the connexion slightly preponderates in favour of his descent from the Scyri.

His father was Aedico or Idico, a name which suggests Edeco the Hun, who was suborned by the Byzantine court to plot the assassination of his master Attila. There are, however,

1 Odo must be distinguished from two English prelates of the same name and also from an English earl. Odo or Oda (d. 959), archbishop of Canterbury, was bishop of Ramsbury from 927 to 942, and went with King Æthelstan to the battle of Brunanburh in 937. Odo of Whithorn, archbishop of Canterbury, and he appears to have been an able and conscientious ruler of the see. He had great influence with King Edwy, whom he had crowned in 956. Odo (d. 1000), abbot of Battle, was a monk of Christ Church, Canterbury. It was probably at this house at the time when Thomas Becket was murdered. In 1175 he was chosen abbot of Battle, and on two occasions the efforts of Henry II. alone prevented him from being elected archbishop of Canterbury. Odo or Odda (d. 1066), a relative of Edward the Confessor, during whose reign he was an earl in the west of England, built the minster at Deerhurst in Gloucestershire.

some strong arguments against this identification. A certain Edica, chief of the Scyri, of whom Jordanes speaks as defeated by the Ostrogoths, may more probably have been the father of Odoacer, though even in this theory there are some difficulties, chiefly connected with the low estate in which he appears before us in the next scene of his life, when as a tall young recruit for the Roman armies, dressed in a sordid vesture of skins, on his way to Italy, he enters the cell of Severinus, a noted hermit-saint of Noricum, to ask his blessing. The saint had an inward premonition of his future greatness, and in blessing him said, "Fare onward into Italy. Thou who art now clothed in vile raiment wilt soon give precious gifts unto many."

Odoacer was probably about thirty years of age when he thus left his country and entered the imperial service. By the year 472 he had risen to some eminence, since it is expressly recorded that he sided with the patrician Ricimer in his quarrel with the emperor Anthemius. In the year 475, by one of the endless revolutions which marked the close of the Western empire, the emperor Nepos was driven into exile, and the successful rebel Orestes was enabled to array in the purple his son, a handsome boy of fourteen or fifteen, who was named Romulus after his grandfather, and nicknamed Augustulus, from his inability to play the part of the great Augustus. Before this puppet emperor had been a year on the throne the barbarian mercenaries, who had been the cause of the Revolution of 475, rebelled against him, and Odoacer, finding himself deserted by his allies, turned to the sea to find his fortune. He rose in mutiny, demanding to be made proprietors of one-third of the soil of Italy. To this request Orestes returned a peremptory negative. Odoacer now offered his fellow-soldiers to obtain for them all that they desired if they would seat him on the throne. On the 23rd of August 476 he was proclaimed king; five days later Orestes was made prisoner at Placentia and beheaded; and on the 4th of September his brother Paulus was defeated and slain near Ravenna. Rome at once accepted the new ruler. Augustulus was compelled to descend from the throne, but his life was spared.

Odoacer was forty-two years of age when he thus became chief ruler of Italy, and he reigned thirteen years with undisputed sway. Our information as to this period is very slender, but we can perceive that the administration was conducted as much as possible on the lines of the old imperial government. The settlement of the barbarian soldiers on the lands of Italy probably affected the great landowners rather than the labouring class. To the herd of coloni and servi, by whom in their various degrees the land was actually cultivated, it probably made little difference, except as a matter of sentiment, whether the master whom they served was an Italian or a Ruman. We have one more interesting example, though in a way, such a transfer of land with its appurtenant slaves and cattle, in the donation made by Odoacer himself to his faithful follower Piersius. Few things bring more vividly before the reader the continuity of legal and social life in the midst of the tremendous ethical changes of the 5th century than the perusal of such a record.

The same fact, from a slightly different point of view, is illustrated by the curious history (recorded by Malchus) of the embassies to Constantinople. The dethroned emperor Nepos sent ambassadors (in 477 or 478) to Zeno, emperor of the East, begging his aid in the reconquest of Italy. These ambassadors met a deputation from the Roman senate, sent nominally by the command of Augustulus, really no doubt by that of Odoacer, the purport of whose commission was that they did not need a separate emperor. One was sufficient to defend the borders of either realm. The senate had chosen Odoacer, whose knowledge of military affairs and whose statesmanship admirably fitted him for preserving order in that part of the world, and they therefore prayed Zeno to confer upon him the dignity of patrician, and entrust the government of Italy to his care. Zeno returned a harsh answer to the senatus-consultum, threatening them to return to their allegiance to Nepos. In fact, however, he did nothing for the fallen emperor, but accepted the new order of things, and even addressed Odoacer as patrician. On the other hand, the latter

8 Published in Marini's Papiri diplomatici (Rome, 1815, Nos. 82 and 83) and in Spangenberg's Juris Romani Tabulae (Leipzig, 1822, pp. 164-173), and well worthy of careful study.
sent the ornaments of empire, the diadem and purple robe, to Constantineople as an acknowledgment of the fact that he did not claim supreme power. Our information as to the actual title assumed by the new ruler is somewhat confused. He does not appear to have called himself king of Italy. His kingdom seems to have marked only his relation to his Teutonic followers, among whom he was "king of the Turfingi," "king of the Heruli," and so forth, according to the nationality with which he was dealing. By the Roman inhabitants of Italy he was addressed as "dominus noster," but his right to exercise power was in their eyes, rest, in theory, on his recognition as a princeps by the Byzantine Augustus. At the same time he marked his own high pretensions by assuming the prefix Flavius, a reminiscence of the early emperors, to which the barbarian rulers of realms formed out of the Roman state seem to have been peculiarly partial. His internal administration was probably, upon the whole, wise and moderate, though we hear some complaints of financial oppression, and he may be looked upon as a not altogether unworthy predecessor of Theodoric.

In the history of the papacy Odoacer figures as the author of a decree promulgated at the election of Felix II. in 483, forbidding the pope to alienate any of the lands or ornaments of the Roman Church, and threatening any pope who should infringe this edict with anathema. This decree was loudly condemned in a synod held in 496 by Pope Symmachus as an unwarrantable interference of the civil power with the concerns of the church.

The chief events in the foreign policy of Odoacer were his Dalmatian and Ruman wars. In the year 480 the ex-emperor Nepos, who ruled Dalmatia, was traitorously assassinated in Dioecletian's palace at Spalato by the counts Viator and Ovidia. In the following year Odoacer invaded Dalmatia, slew the murderer Ovidia, and reannexed Dalmatia to the Western state. In 487 he appeared as an invader in his own native Danubian lands. War broke out between him and Felctheus, king of the Rumanian Odoacer entered the Rumanian territory, defeated Felctheus, and carried him and his "noxious wife" Gisa prisoners to Ravenna. In the following year Frederick, son of the captive king, endeavoured to raise again the fallen fortunes of his house, but was defeated by Onulf, brother of Odoacer, and, being forced to flee, took refuge at the court of Theodoric the Ostrogoth, at Sistrova on the lower Danube.

This Ruman war was probably an indirect cause of the fall of Odoacer. His increasing power rendered him too formidable to the Romans, whose alliance he had from time been growing less friendly. At the same time, Zeno was embarrassed by the formidable neighbourhood of Theodoric and his Ostrogothic warriors, who were almost equally burdensome as enemies or as allies. In these circumstances arose the plan of Theodoric's invasion of Italy, a plan by whom originated it would be difficult to say. Whether the land when conquered was to be held by the Ostrogoth in full sovereignty, or administered by him as lieutenant of Zeno, is a point upon which our information is ambiguous, and which was perhaps intentionally left vague by the two contracting parties, whose chief anxiety was not to see another's faces again. The details of the Ostrogothic invasion of Italy belong properly to the life of Theodoric. It is sufficient to state here that he entered Italy in August 489, defeated Odoacer at the Isontius (Isonzo) on the 28th of August, and at Verona on the 30th of September. Odoacer then shut himself up in Ravenna, and there maintained himself for four years, with one brief gleam of success, during which he emerged from his hiding-place and fought the battle of the Adda. In August 493 a great defeat, specially from Ravenna (10th July 492) was again the occasion of a murderous defeat. At length, the famine in Ravenna having become almost intolerable, and the Goths despairing of ever taking the city by assault, negotiations were opened for a compromise (25th February 493). John, archbishop of Ravenna, acted as mediator. It was stipulated that Ravenna should be surrendered, that Odoacer's life should be spared, and that he and Theodoric should be recognized as joint rulers of the Roman state. The arrangement was evidently a precarious one, and was soon terminated by the treachery of Theodoric. He invited his rival to a banquet in the palace of the Laurentum on the 15th of March, and there slew him with his own hand. Where is God now, cried Odoacer when he perceived the ambush into which he had fallen! The coup de grâce dealt by my kinsmen, shouted Theodoric, and close his rival with the broadsword from shoulder to flank. Onulf, the brother of the murdered king, was shot down while attempting to escape through the palace garden, and Thelan, his son, was not long after put to death by order of the conqueror. Thus perished the whole race of Odoacer.

Literature.—The chief authorities for the life of Odoacer are the so-called "Anonymus Valesii," generally printed at the end of Ammianus Marcellinus; the Life of Seviricus, by Eusebius; the church historian "Savinius Anonymus" (both in Roncalli's collection); and the Byzantine historians, Malchus and John of Antioch. A fragment of the latter historian, unknown when Gibbon wrote, is to be found in the fifth volume of Müller's Fragmenta Historiorum Gregorianorum. There is a thorough investigation of the history of Odoacer in R. Pallmann's Geschichte der Völkerwanderung, vol. ii. (Weimar, 1864). See also T. Hodgkin, Italy and her Invaders, vol. iii. (Oxford, 1885).

Odoacer, an Italian jurist of the 13th century. He was born at Bologna and studied law under Baldinius and Accursius. After having practised as an advocate both in Italy and France, he became professor at Bologna in 1228. The commentaries on Roman law attributed to him are valuable as showing the growth of the study of law in Italy, and for their biographical details of the jurists of the 12th and 13th centuries. Odoacer died at Bologna on the 3rd of December 1265.

Over his name appeared Lectures in codex Irenaei (Lyons, 1480) Lecturae in digestum veteris (Paris, 1504), Summa de libellis formandis (Strassburg, 1510), Lecturae in tres libros (Venice, 1514), and Lecturae in digestum novum (Lyons, 1552).

O'Donnell, the name of an ancient and powerful Irish family, lords of Tyrconnell in early times, and the chief rivals of the O'Neill in Ulster. Like the family of O'Neill (q.v.), that of O'Donnell was descended from Niall of the Nine Hostages, king of Ireland at the beginning of the 5th century; the O'Neill, or Cinel Owen, tracing their pedigree to Owen (Eoghan), and the O'Donnell, or Cinel Connell, to Connall Gulban, both sons of Niall. Tyrconnell, the district named after the Cinel Connell, where the O'Donnells held sway, comprised the greater part of the modern county of Donegal except the peninsula of Inishowen; and since it lay contented, it was of great importance to the O'Neill of Tyrone, who were continually attempting to assert their supremacy over it, the history of the O'Donnells is for the most part a record of tribal warfare with their powerful neighbours, and of their own efforts to make good their claims to the overlordship of northern Connaught.

The first chieftain of mark in the family was Goiffraud (Godfrey), son of Donnell Mor O'Donnell (d. 1241). Goiffraud, who was "inaugurated" as "The O'Donnell," i.e. chief of the clan, in 1248, made a successful inroad into Tyrone against Brian O'Neill in 1252. In 1257 he drove the English out of northern Connaught, after a single combat with Maurice Fitzgerald in which both warriors were wounded. O'Donnell while still incapacitated by his wound was summoned by Brian O'Neill to give hostages in token of submission. Carried on a litter at the command of his lord he gave battle to O'Neill, whom he defeated with severe loss in prisoners and cattle; but he died of his wound immediately afterwards near Letterkenny, and was succeeded in the chieftainship by his brother Donnell Oge, who ruled the O'Donnells from Scotland in time to withstand successfully the demands of O'Neill.

In the 16th century, when the English began to make determined efforts to bring the whole of Ireland under subjection to the crown, the O'Donnells of Tyrconnell played a leading part; co-operating at times with the English, especially when such co-operation appeared to promise triumph over their ancient enemies the O'Neills, at other times joining with the latter against the English authorities.

The Cinel, or Kinel, was a group of related clans occupying an extensive district. See P. W. Joyce, A Social History of Ireland (London, 1903), i. 166.
O’DONNELL (FAMILY)

Manus O'Donnell (d. 1564), son of Hugh Dubh O'Donnell, was left by his father to rule Tyrconnel, though still a mere youth, when Hugh Dubh went on a pilgrimage to Rome about 1512. Hugh Dubh had been chief of the O’Donnells during one of the bitterest and most protracted of the feuds between his clan and the O’Neills, which in 1491 led to a war lasting more than ten years. On his return from Rome in broken health after two years’ absence, his son Manus, who had proved himself a capable leader in defending his country against the O’Neills, retained the chief authority. A family quarrel ensued, and when Hugh Dubh appealed for aid against his son to the Maguires, Manus made an alliance with the O’Neills, by whose assistance he established his hold over Tyrconnel. But in 1522 the two great northern clans were again at war. Conn Baccach O'Neill, 1st earl of Tyrone, determined to bring the O’Donnells under thorough subjection. Supported by several septs of Munster and Connaught, and assisted also by English contingents and by the MacDonnells of Antrim, O’Neill took the castle of Ballyshannon, and after devastating a large part of Tyrconnel he encamped at Knockavoe, near Strabane. Here he was surprised at night by Hugh Dubh and Manus O’Donnell, and routed with the loss of 300 men and an immense quantity of booty. Although this was one of the bloodiest fights that ever hap- pened between O’Neill’s and O’Donnell’s, it brought the war to an end; and in 1531 O’Donnell applied to the English government for protection, giving assurances of allegiance to Henry VIII. In 1532 Lord Thomas Fitzgerald and his five uncles were executed for rebellion in Munster, and the English government made every effort to lay hands also on Gerald, the youthful heir to the earldom of Kildare, a boy of twelve years of age who was in the secret custody of his aunt Lady Eleanor McCarthy. This lady, in order to secure a powerful protector for the boy, accepted an offer of marriage by Manus O’Donnell, who on the death of Hugh Dubh in July 1537 was inaugurated The O’Donnell. Conn O’Neill was a relative of Gerald Fitzgerald, and this event accordingly led to the formation of the Geraldine League, a federation which combined the O’Neills, the O’Donnells, the O’Briens of Thomond, and other powerful clans; the primary object of which was to restore Gerald to the earldom of Kildare, but which afterwards aimed at the complete overthrow of English rule in Ireland. In August 1539 Manus O’Donnell and Conn O’Neill were defeated with heavy loss by the lord deputy at Lake Bellahoe, in Monaghan, which crippled many of their forces. O’Neill himself made unceasing efforts to assert the supremacy of the O’Donnells in north Connaught, where he compelled O’Conor Sligo to acknowledge his over- lordship in 1539. In 1542 he went to England and presented himself, together with Conn O’Neill and other Irish chiefs, before Henry VIII., who promised to make him earl of Tyrconnel, though he refused O’Donnell’s request to be made earl of Sligo. In his later years Manus was troubled by quarrels between his sons Calvagh and Hugh MacManus; in 1555 he was made prisoner by Calvagh, who deposed him from all authority in Tyrconnel, and he died in 1564. Manus O’Donnell, though a fierce warrior, was hospitable and generous to the poor and the Church. He is described by the Four Masters as “a learned man, skilled in many arts, gifted with a profound intellect, and the knowledge of every science.” At his castle of Portanynod near Strabane he supervised if he did not actually dictate the writing of the Life of Saint Columbkille in Irish, which is preserved in the Bodleian Library at Oxford. Manus was several times married. His first wife, Joan O’Reilly, was the mother of Calvagh, and two daughters, Nuala and Maighret, was wife of the famous rebel Shane O’Neill. His second wife, Hugh’s mother, by whom he was ancestor of the earls of Tyrconnel (see below), was Judith, sister of Conn Baccach O’Neill, 1st earl of Tyrone, and aunt of Shane O’Neill.

Calvagh O’Donnell (d. 1566), eldest son of Manus O’Donnell, in the course of his above-mentioned quarrel with his father and his half-brother Hugh, sought aid in Scotland from the MacDonnells, who assisted him in deposeing Manus and securing the lordship of Tyrconnel for himself. Hugh then appealed to Shane O’Neill, who invaded Tyrconnel at the head of a large army in 1557, desiring to make himself supreme throughout Ulster, and encamped on the shore of Lough Swilly. Calvagh, acting apparently on the advice of his father, who was his prisoner and who remembered the successful night attack on Conn O’Neill at Knockavoe in 1522, surprised the O’Neills in their camp at night and routed them with the loss of all their spoils. Calvagh was then recognized by the English government as lord of Tyrconnel; but in 1561 he and his wife were captured by Shane O’Neill in the monastery of Kildonan. His wife, Catherine Maclean, who had previously been the wife of the earl of Argyll, was kept by Shane O’Neill as his mistress and bore him several children, though grossly ill-treated by her savage capitor; Calvagh himself was subjected to atrocious torture during the three years that he remained O’Neill’s prisoner. He was released in 1564 on conditions which he had no intention of fulfilling; and crossing to England he threw himself on the mercy of Queen Elizabeth. In 1566 Sir Henry Sidney by the queen’s orders marched to Tyrconnel and restored Calvagh to his rights. Calvagh, however, died in the same year, and as his son Conn was a prisoner in the hands of Shane O’Neill, his half-brother Hugh MacManus was inaugurated The O’Donnell in his place. Hugh, who in the family feud with Calvagh had killed his brother, was deposed and a bitter feud between the two O’Donnells was renewed in an attempt to crush the hereditary enemy of his family, and in 1567 he utterly routed Shane at Letterkenny with the loss of 1300 men, compelling him to seek refuge with the MacDonnells of Antrim, by whom he was treacherously put to death. In 1592 Hugh abided in favour of his son Hugh Roe O’Donnell (see below); but there was a member of the elder branch of the family who resented the passing of the chieftainship to the descendants of Manus O’Donnell’s second marriage. This was Niall Garve, second son of Calvagh’s son Conn. His elder brother was Hugh of Ramelton, whose son John, an officer in the Spanish army, was father of Hugh Baldearg O’Donnell (d. 1704), known in Spain as Count O’Donnell, who commanded an Irish regiment as brigadier in the Spanish service. This officer came to Ireland in 1606 and raised an army in Ulster for the service of James II., afterwards deserting to the side of William III., from whom he accepted a pension.

Niall Garve O’Donnell (1560–1626), who was incensed at the elevation of his cousin Hugh Roe to the chieftainship in 1585, immediately allied himself with the rebels. Hugh Roe was the half-brother of Hugh, and a bitter feud between the two O’Donnells was the result. Niall Garve made terms with the English government, to whom he rendered valuable service both against the O’Neills and against his cousin. But in 1601 he quarrelled with the lord deputy, who, though willing to establish Niall Garve in the lordship of Tyrconnel, would not permit him to enforce his supremacy over Cahir O’Dogherty in Inishowen. After the departure of Hugh Roe from Ireland in 1602, Niall Garve and Hugh Roe’s brother Rory went to London, where the privy council endeavoured to arrange the family quarrel, but failed to satisfy Niall. Charged with complicity in Cahir O’Dogherty’s rebellion in 1608, Niall Garve was sent to the Tower of London, where he remained till his death in 1626. He married his cousin Nuala, sister of Hugh Roe and Rory O’Donnell. When Rory fled with the earl of Tyrone to Rome in 1607, Nuala, who had deserted her husband when he joined the English against her brother, accompanied him, taking with her her daughter Grania. She was the subject of an Irish poem, of which an English version was written by Thomas Campion. Garve married by proxy Margaret, whose son was Hugh MacManus O’Donnell, and grandson of Manus O’Donnell by his second marriage with Judith O’Neill, was the most celebrated member of his clan. His mother was Ineen Dubh, daughter of James MacDonnell of Kintyre; his sister was the second wife of Hugh O’Neill, and lady of Tyrone. These family connexions with the Hebridean Scots and with the O’Neills made the lord deputy, Sir John Perrot, afraid of a powerful combination against the English government, and induced him to
O’DONNELL, H. J.

establish garrisons in Tyrconnel and to demand hostages from Hugh MacManus O’Donnell, which the latter refused to hand over. In 1587 Petrot conceived a plan for kidnapping Hugh Roe (Hugh the Red), now a youth of fifteen, who had already given proof of exceptional manliness and sagacity. A merchant vessel laden with Spanish wines was sent to Lough Swilly, and anchoring off Rathmullan, where the boy was residing in the castle of MacSweeney his foster parent, Hugh Roe with some youthful companions was enticed on board, when the ship immediately set sail and conveyed the party to Dublin. The boys were kept in prison for more than three years. In 1591 young O’Donnell made two attempts to escape, the second of which proved successful; and after enduring terrible privations from exposure in the mountains he made his way to Tyrconnel, where in the following year his father handed the chieftainship over to him. Red Hugh lost no time in leading an expedition against Turlough Luineach O’Neill, then at war with his kinsman Hugh, earl of Tyrone, with whom O’Donnell was in alliance. At the same time he sent assurances of loyalty to the lord deputy, whom he met in person at Dundalk in the summer of 1592. But being determined to vindicate the traditional claims of his family in north Connaught, he aided Hugh Maguire against the English, though on the advice of Tyrone he abstained from a time for committing himself to the cause; however, in 1595 the English killed Hugh Roe and taken with the women and children flung into the river from its walls by order of Sir Richard Bingham, the English governor of Connaught, O’Donnell sent urgent messages to Tyrone for help, and while he himself hurried to Derry to withstand an invasion of Scots from the isles, Maguire defeated the English with heavy loss at Bellanabriska (The Ford of the Biscuits). In 1595 Red Hugh again invaded Connaught, putting to the sword every soul above fifteen years of age unable to speak Irish; he captured Longford and soon afterwards gained possession of Sligo, which placed north Connaught at his mercy. In 1596 he agreed in conjunction with Tyrone to a cessation of hostilities with the English, and consented to meet commissioners from the government near Dundalk. The terms he demanded were, however, refused; and his determination to continue the struggle was strengthened by the prospect of help from Philip II. of Spain, with whom he and Tyrone had been in correspondence. In the beginning of 1597 he made another inroad into Connaught, where O’Conor Sligo had been set up by the English as a counterpoise to O’Donnell. He devastated the country and returned to Tyrconnel rich with spoils; in the following year he shared in Tyrone’s victory over the English at the Yellow Ford on the Blackwater; and in 1599 he defeated an attempt by the English under Sir Conyers Clifford, governor of Connaught, to succour O’Conor Sligo in Collooney castle, which O’Donnell captured, forcing Sligo to submission. The government now sent Sir Henry D’Owra to Derry, and O’Donnell entrusted to his cousin Niall Garve the task of opposing him. Niall Garve, however, went over to the English, making himself master of O’Donnell’s strongholds of Lifford and Donegal. While Hugh Roe was attempting to retake the latter place in 1601, he heard that a Spanish force had landed in Munster. He marched rapidly to the south, and was joined by Tyrone at Bandon; but a night-attack on the English besieging the Spaniards in Kinsale having utterly failed, O’Donnell, who attributed the disaster to the incapacity of the Spanish commander, took ship to Spain on the 6th of January 1602 to lay his complaint before Philip III. He was favourably received by the Spanish king, but he died at Simancas on the 10th of September in the same year.

Rory O’Donnell, 1st earl of Tyrconnel (1575–1608), second son of Hugh MacManus O’Donnell, and younger brother of Hugh Roe, accompanied the latter in the above-mentioned expedition to Kinsale; and when his brother sailed for Spain he transferred his authority as chief to Rory, who led the O’Donnell contingent back to the north. In 1602 Rory gave in his allegiance to Lord Mountjoy, the lord deputy; and in the following summer he went to London with the earl of Tyrone, where he was received with favour by James I., who created him earl of Tyrconnel. In 1605 he was invested with authority as lieutenant of the king in Donegal. But the arrangement between Roe and O’Donnell, which the latter urged upon the government was displeasing to both O’Donnell’s allies, Roger, like Hugh Roe before him, entered into negotiations with Spain. His country, had been reduced to a desert by famine and war, and his own reckless extravagance had plunged him deeply in debt. These circumstances as much as the fear that his designs were known to the government may have persuaded him to leave Ireland. In September 1607 “the flight of the earls” (see O’Neill) took place, Tyrconnel and Tyrone reaching Rome in April 1608, where Tyrconnel died on the 28th of July. His wife, the beautiful daughter of the earl of Kildare, was left behind in the haste of Tyrconnel’s flight, and lived to marry Nicholas Barnwell, Lord Kingsland. By Tyrconnel she had a son Hugh; and among other children a daughter Mary Stuart O’Donnell, who, born after her father’s flight from Ireland, was so named by James I. after his mother. This lady, after many romantic adventures disguised in male attire, married a man called O’Gallagher and died in poverty on the continent.

Rory O’Donnell was attainted by the Irish parliament in 1614, but his son Hugh, who lived at the Spanish Court, assumed the title of earl; and the last titular earl of Tyrconnel was this Hugh, son of the above-mentioned Sir Rory O’Donnell. But by who he was appointed Hugh Baldean O’Donnell (1666–1735), a general of the famous Irish brigade in the French service, whose father, Turlough, was a son of Hugh Dubh O’Donnell, elder brother of Manus, son of an earlier Hugh Dubh mentioned above. Daniel served in the French army in the wars of the period, fighting against Marlborough at Oudenarde and Malplapueit at the head of an O’Donnell regiment. He died in 1735.

The famous Cathach, or Battle-Book of the O’Donnells, was in the possession of General Daniel O’Donnell, from whom it passed to more modern representatives of the family, who presented it to the Royal Irish Academy, where it is preserved as a relic, of which a curious legend is told (see W. P. Joyce, A Social History of Ancient Ireland, vol. i. p. 501), is a Psalter said to have belonged to Saint Columba, a kinsman of the O’Donnells, which was carried by them in battle as a charm or talisman to secure victory. Two other Cathachs, the Book of Tyrconnel and O’Donnell’s with ancient Irish literature, may be mentioned. The family of O’Clery, to which three of the celebrated “Four Masters” belonged, were hereditary Ollaves (doctors of history, music, law, &c.) attached to the family of Tyrconnel. This family of O’Clery, with the O’Donnells, were of the most ancient Irish MSS., was in the possession of the O’Donnells in the 14th century; and the estimation in which it was held at that time is proved by the fact that it was given to the O’Conors of Connaught as ransom for an important prisoner, and was forcibly recovered some years later.

See O’Neill, and the authorities there cited. (R. J. M.)

O’DONNELL, HENRY JOSPH (1760–1834), count of La Bisbal, Spanish soldier, was descended from the O’Donnells who left Ireland after the battle of the Boyne.1 Born in Spain, he early entered the Spanish army, and in 1810 became general, receiving a command in Catalonia, where in that year he earned his title and the rank of field-marshal. He afterwards held posts of great responsibility under Ferdinand VII., whom he served on the whole with constancy; the events of 1823 compelled his flight into France, where he was interned at Limoges, and where he died in 1834. His second son LEOPOLD O’DONNELL (1800–1867), duke of Tetuan, Spanish general and statesman, was born at Santa Cruz, Tenerife, on the 12th of January 1809. He fought in the army of Queen Christina, where he attained the rank of general of division; and in 1840 he accompanied the queen into exile. He failed in an attempt to effect a rising in her favour at Pamplona in 1841, but took a more successful part in the movement which led to the overthrow and exile of

1 A branch of the family settled in Austria, and General Karl O’Donnell, count of Tyrconnel (1715–1777), held important commands during the Seven Years’ War. The name of a descendant figures in the history of the Italian and Hungarian campaigns of 1848 and 1849.
O'DONOVAN, E.—ODONTORNITHES

Espartero in 1843. From 1844 to 1848 he served the new government in Cuba; after his return he entered the senate. In 1854 he became war minister under Espartero, and in 1856 he plotted successfully against his chief, becoming head of the cabinet from the July revolution until October. This rank he again reached in July 1858; and in December 1859 he took command of the expedition to Morocco, and received the title of duke after the surrender of Tetuan. quitting office in 1863, he again resumed it in June 1865, but was compelled to resign in favour of Narvaez in 1866. He died at Bayonne on the 5th of November 1867.

There is a Life of Leopold O’Donnell in La Corona de laurel, by Manuel Ibo Alfaro (Madrid, 1860).

O'DONOVAN, EDMUND (1844-1883), British war-correspondent, was born at Dublin on the 13th of September 1844, the son of John O'Donovan (1806-1861), a well-known Irish archaeologist and topographer. In 1866 he began to contribute to the Irish Times and other Dublin papers. After the battle of Sedan he joined the Foreign Legion of the French army, and was wounded and taken prisoner by the Germans. In 1873 the Carlist rising attracted him to Spain, and he wrote many newspaper letters on the campaign. In 1876 he represented the London Daily News during the rising of Bosnia and Herzegovina against the Turks, and in 1879, for the second time, made his adventurous journey to Merv. On his arrival at Merv, the Turcomans, suspecting him to be a Russian spy, detained him. It was only after several months' captivity that O'Donovan managed to get a message to his principals through to Persia, whence it was telegraphed to England. These adventures he described in The Merv Oasis (1882). In 1883 O'Donovan accompanied the ill-fated expedition of Hicks Pasha to the Egyptian Sudan, and perished with it.

O'DONOVAN, WILLIAM RUDOLF (1844— ), American sculptor, was born in Preston county, Virginia, on the 28th of March 1844. He had no technical art training, but after the Civil War, in which he served in the Confederate army, he opened a studio in New York City and became a well-known sculptor, especially of memorial pieces. Among these are statues of George Washington (in Caracas), Lincoln and Grant (Prospect Park, Brooklyn), the captors of Major André (Tarrytown, N.Y.), and Archbishop Hughes (Fordham University, Fordham, N.Y.), and a memorial tablet to Bayard Taylor (Cornell University). In 1878 he become an associate of the National Academy of Design.

ODONTORNITHES, the term proposed by O. C. Marsh (Am. Journ. Sci. ser 3, v. 1873 pp. 161-162) for birds possessing teeth (Gr. δοντος, tooth, ὄξος, ὄμορος, bird), notably the genera Hesperornis and Ichthyornis from the Cretaceous deposits of Kansas. In 1875 (op. cit. x. pp. 403-408) he divided the "subclass" into Odontolcae, with the teeth standing in grooves, and Odontotormae, with the teeth in separate alveoles or sockets. In his magnificent work, Oedontornithes: A monograph on the extinct toothed birds of North America, New Haven, Connecticut, 1880, he logically added the Saururae, represented by Archaeopteryx, as a third order. As it usually happens with the selection of a single anatomical character, the resulting classification was unnatural. In the present case the Odontornithes are a heterogeneous assembly, and the fact of their possessing teeth proves nothing but that birds, possibly all of them, still had these organs during the Cretaceous epoch. This, by itself, is a very interesting point, showing that birds, as a class, are the descendants of well-toothed reptiles, to the complete exclusion of the Chelonia with which various authors persistently try to connect them. The Odontornithes, whether larger or less than Cretaceous age are known to have teeth, and concerning recent birds they possess not even embryonic vestiges.

E. Geoffroy St Hilaire stated in 1821 (Ann. Gén. Sci. Phys. viii. pp. 373-380) that he had found a considerable number of tooth-germs in the upper and lower jaws of the parrot Palaearctos torquatus. E. Blanchard ("Observations sur le systéme dentaire chez les oiseaux," Comptes rendus 50, 1860, pp. 540-542) felt justified in recognizing flases of dentine. However, M. Braun (Arbeit Zool. Inst., Würzburg, v. 1879) and especially P. Fraisse (Phys. Med. Ges., Würzburg, 1880) have shown that the structures in question are not the kind as the well-known serrated "teeth" of the bill of anserine birds. In fact the papillae observed in the embryonic birds are the soft cutaneous extensions into the surrounding horny sheath of the bill, comparable to the well-known nutritive papillae in a horse's hoof. They are easily exposed in the well-macerated jaw of a parrot, after removal of the horny sheath. Occasionally calcification occurs in or around these papillae, as it does regularly in the "egg-tooth" of the embryos of all birds.

The best known of the Odontornithes are Hesperornis regalis, standing about 3 ft. high, and the somewhat taller H. crassipes. Both show the general configuration of a diver, but it is only by analogy that Hesperornis can be looked upon as ancestral to the Colymbiformes. There are about fourteen teeth in a groove of the maxilla and about twenty-one in the mandible; the vertebrae are typically heterocoels; of the wing-bones only the very slender and long humerus is known; clavicles slightly reduced; coracoids short and broad, movably connected with the scapula; sternum very long, broad and quite flat, without the trace of a keel. Hind limbs very strong and of the Colymbine type, but the tail or foure capitulum of the metatarsus is the strongest and longest, an unique arrangement in an otherwise typically steganopodous foot. The pelvis shows much resemblance to that of the divers, but there is still an incisura ischiadica instead of a foramen. The tail is composed of about twelve vertebrae, without a pygostyle. Enaliornis of the Cambridge Greensand of England, and Baptornis of the mid-Cretaceous of North America, are probably allied, but imperfectly known. The vertebrae are biconvex, with heterocoels indications in the cervicalis; the metatarsal bones appear still somewhat imperfectly anchylosed. The absence of a keel misled Marsh who suspected relationship of Hesperornis with the Ratitae, and L. Dollo went so far as to call it a carnivorous, aquatic ostrich (Bull. Sci. Départ. du Nord, ser. 2, iv. 1881, p. 390), and this mistaken notion of the "swimming ostrich" was popularized by various authors. B. Vetter (Festschr. Ges. Isis., Dresden, 1885) rightly pointed out that Hesperornis was a descendant of Carinata, but adapted to aquatic life, implying reduction of the keel. Lastly, M. Führbrüger (Untersuchungen, Amsterdam, 1888, pp. 1543, 1595, 1580) relegated it, together with Enaliornis and Colymbosoma, to the group Podicipitiformes. The present writer does not feel justified in going so far.

On account of their various, decidedly primitive characters, he prefers to look upon the Odontolcae as a separate group, one of the three divisions of the Neornithes, as birds which form an early offshoot from the later Colymbo-Pelargomorphous stock; in adaptation to a marine, swimming life they have lost the power of flight, as is shown by the absence of the keel and by the great reduction of the wing-skeleton, just as in another direction, away from the later Alectoromorphous stock the Ratitae have specialized as runners. It is only in so far as the loss of flight is correlated with the absence of the keel that the Odontolcae and the Ratitae bear analogy to each other.

There remain the Odontotormae, notably Ichthyornis victor, I. dispar, Aptornis and Graculus of the middle and upper Cretaceous of Kansas. The teeth stand in separate alveoles; the two halves of the mandible are, as in Hesperornis, without a symphysis. The vertebrae are amphiocoelous, but at least the third cervical has a reduced keel. The manubrium and sternum consists of five free vertebrae, followed by a rather small pygostyle. Shoulder girdle and sternum well developed and of the typical carinate type. Pelvis still with incisura ischiadica. Marsh based the restoration of Ichthyornis, which was obviously a well-flying aquatic bird, upon the skeleton of a tern, a relationship which cannot be supported. The teeth, vertebrae, pelvis and the small brain are all so many less characters that the Odontotormae may well form a separate, and very low, order of the typical Carinatae, of course near the Colymbomorphous Legion. (H. F. G.)
ODORIC (c. 1286-1331), styled “of Pordenone,” one of the chief travellers of the later middle ages, and a Beatus of the Roman Church, was born at Villa Nuova, a hamlet near the town of Pordenone in Friuli, in or about 1286. According to the ecclesiastical biographers, in early years he took the vows of the Franciscan order and joined their convent at Udine, the capital of Friuli.

Friar Odoric was despatched to the East, where a remarkable extension of missionary action was then taking place, about 1316-1318, and did not return till the end of 1320 or beginning of 1329; but, as regards intermediate dates, all that we can deduce from his narrative or other evidence is that he was in western India soon after 1321 (possibly certainly in 1322) and that he spent three years in China between the opening of 1323 and the close of 1326. His route to the East lay by Trebizond and Erzerum to Tabriz and Sultanieh, in all of which places the order had houses. From Sultanieh he proceeded by Kashan and Yazd, and turning thence followed a somewhat devious route by Persepolis and the Shiraz and Bagdad regions, to the Persian Gulf. At Hormuz he embarked for India, landing at Thana, near Bombay. At this crisis for odyllic order of friars of them Italian and fourth a Georgian, who, shortly before made an attack on the hands of the Mahomedan governor. The bones of the martyred friars had been collected by Friar Jordanus of Séverac, a Dominican, who carried them to Supera—the Sufara of the ancient geographers, near the modern Bassein, about 26 m. north of Bombay—and buried them there. Odoric tells that he disinterred these relics and carried them with him on his further travels. In the course of these he visited Malabar, touching at Pandarani (20 m. north of Calicut), at Cranganore, and at Kulam or Quilin, proceeding thence, apparently, to Ceylon and to the shrine of St Thomas at Maylapur near Madras. From India he sailed in a junk to Sumatra, visiting various ports on the northern coast of that island, and thence to Java, to the coast (it would seem) of Borneo, to Champa (South Cochin-China), and to Canton, at that time known to western Asiatists as Chin-Kalan or Great China (Mahanin). From Canton he travelled overland to the great ports of Fukien, at one of which, Zayton or Amoy harbour, he found two houses of friars; in one of these he deposited the bones of the friars of the order, who had been buried in India. From Fuchow he struck across the mountains into Cheh-kiang and visited Hang-chow, then renowned, under the name of Canay, Khanass, or Quiniss (i.e. Kingsyes or royal residence), as the greatest city in the world, of whose splendours Odoric, like Marco Polo, Marignolli, or Ibn Batuta, gives notable details. Passing northward by Nanking and crossing the Yangtze-kiang, Odoric embarked on the Great Canal and travelled to Cambolec (otherwise Cambaleth, Cambalac, &c.) or Peking, where he remained for three years, attached, no doubt, to one of the churches founded by Archbishop John of Monte Corvino, at this time in extreme old age. Returning overland across Asia, through the Land of Prester John and through Casan, the adventurous traveller seems to have entered Tibet, and even perhaps to have visited Lhasa. After this we trace the friar in northern Persia, in Millestorte, once famous as the Land of the Assassins in the Elburz highlands.

No further indications of his homeward route (to Venice) are given, though it is almost certain that he passed through Tabriz. The vague and fragmentary character of the narrative, in this section, forcibly contrasts with the clear and careful tracing of the outward way. During a part at least of these long journeys the companionship of Odoric was Friar James, an Irishman, as appears from a report in the public books of Udine, showing that shortly after Odoric's death a present of two marks was made to this Irish friar, Socio beatit Fratris Odorici, amore Dei et Odoric. Shortly after his return Odoric bestowed himself to the Minoret house attached to St Anthony's at Padua, and it was there that in May 1350 he related the story of his travels, which was taken down in homely Latin by Friar William of Solagna. Travelling towards the papal court at Avignon, Odoric fell ill at Pisa, and turning back to Udine, the capital of his native province, died in the convent there on the 14th of January 1351.

His vast journeys appears to have made a much greater impression on the laity of his native territory than on his Franciscan brethren. The latter were about to bid him farewell on 13th of January, but the gesta of the chief magistrate of the city interfered and appointed a public funeral; rumors of his wondrous travels and of posthumous miracles were diffused, and excitement spread like wildfire over Friuli and Carniola; the ceremony had to be deferred more than once, and at last took place in presence of the patriarch of Aquileia and all the local dignitaries. Popular acclamation made him an object of devotion, the municipality erected a noble shrine for his body, and his fame as saint and traveller had spread far and wide before the middle of the century, but it was not till four centuries later (1755) that the papal authority formally sanctioned his beatification. A bust of Odoric was set up at Pordenone in 1858.

The numerous copies of Odoric's narrative (both of the original text and of the versions in French, Italian, &c.) that have come down to our time, chiefly from the 14th century, show how speedily and widely it acquired popularity. It does not deserve the charge of mendacity brought against it by some, though the geography of the authors of the first or odd editions of them is not benefited by the liberties which Sir John Mandeville took with it. The substance of that knight's alleged travels in India and Cathay is stolen from Odoric, though amplified with fables from other sources and from his own invention, and garnished with his own unusually clear astronomical notions. We may indicate a few passages which stamp Odoric as a genuine and original traveller. He is the first European, after Marco Polo, who distinctly mentions the name of Sumatra. The cannibalism and community of wives which he attributes to certain races of that island do certainly belong to it, or to islands closely adjoining. His description of sago in the archipelago is not free from errors, but they are the errors of an eye-witness. In China his mention of Canton by the name of Censolam or Censolam (Chin-Kalan), and his descriptions of the custom of fishing with tame cormorants, of the habit of letting the finger-nails grow extravagantly, and of the compression of women's feet, are peculiar to him among the travellers of that age; Marco Polo omits them all.

Seventy-three MSS. of Odoric's narrative are known to exist in Latin, and a few copies in various forms, like the versions printed in the Hague, Vienna, Paris, and London. The first Latin edition was published in 1487 (Venice from a manuscript by R. de Graff) and in 1492 (by G. Mercatius). The first English translation was made by J. H. Parker, in 1515, and the first French, by F. de Tourneaux, in 1528. The works most useful to students of Odoric are (Histor.-polit. Blätter von Philippus und Gorges, vol. xxxii., pp. 507-537). The best editions of Odoric are by G. Vanni, Elogio storico de' gesti del Beato Odorico (Venice, 1710); P. Vyle in Cathay and the Peop|es of the Far East (ed. 1891); and F. C. R. Reichenbach, Flora et mensa mundi, a” universale delle Missioni Francoianee, ii. 379-781, and in Hakluyt's Principal Navigations (1600), ii. 39-67. See also John of Viktring (Ioannes Victorinensis) in Fontes rerum Germaniæ, ed. J. F. Fixell, vol. xix., p. 421; C. A. Wadding, Annales Minorum, a.d. 1351, vol. vii., pp. 123-126; Bartholomew Albizzi, Opus conformitatis, b. Francisci, bk. i.; i. p. 27; 34, 121; 54, 57; 73, 126, 121, &c. (H. Y.; C. R. B.)

ODYLIC FORCE, a term once in vogue to explain the phenomenon of hypnotism (q.v.). In 1845 considerable attention was drawn to the announcement by Baron von Reichenbach of a so-called new "imponderable" or "influence" developed by certain crystals, magnets, the human body, associated with heat, chemical action, or electricity, and existing throughout
the universe, to which he gave the name of odyl. Persons sensitive to odyl saw luminous phenomena near the poles of magnets, or even around the hands or heads of certain persons in whose bodies the force was supposed to be concentrated. In Britain an impetus was given to the study of the subject by the translation in 1838 of Reichenhofen's "Researches on Magnetism, etc., in relation to Vital Force," by Dr. Gregory, professor of chemistry in the university of Edinburgh. These "Researches" show many of the phenomena to be of the same nature as those described previously by F. Mesmer, and even long before Mesmer's time by Swedenborg.

**ODYSSEUS** (in Latin Ulysses, incorrectly written Ulysses), in Greek legend, son of Laërtes and Anticleia, king of Ithaca, a famous hero and typical representative of the Greek race. In Homer he is one of the best and bravest of the heroes, and the favourite of Athena, whereas in later legend he is cowardly and deceitful. Soon after his marriage to Penelope he was summoned to the Trojan war. Unwilling to go, he feigned madness, ploughing a field sown with salt with an ox and an ass yoked together; but Palamedes discovered his deceit by placing his infant child Telemachus in front of the plough; Odysseus afterwards revenged himself by compassing the death of Palamedes. During the war, he distinguished himself as the wisest adviser of the Greeks, and finally, the capture of Troy, which the bravery of Achilles could not accomplish, was attained by Odysseus' stratagem of the wooden horse. After the death of Achilles the Greeks adjudged his armour to Odysseus as the one who had done most to end the war successfully. When Troy was captured he set sail for Ithaca, but was carried by unfavourable winds to the coast of Africa. After encountering many adventures in all parts of the unknown seas, among the lotus-eaters and the Cyclopes, in the isles of Aeolus and Circe and the perils of Scylla and Charybdis, among the laestrygones, and even in the world of the dead, having lost all his ships and companions, he barely escaped with his life to the island of Calypso, where he was detained eight years, an unwilling lover of the beautiful nymph. Then at the command of Zeus he was sent homewards, but was again wrecked on the island of Phaeacia, whence he was conveyed to Ithaca in one of the wondrous Phaeacian ships. Here he found that a host of suitors, taking advantage of the youth of his son Telemachus, were wasting his property and trying to force Penelope to marry one of them. The stratagems and disguises by which with the help of a few faithful friends he slew the suitors are described at length in the *Odyssey*. The only allusion to his death is contained in the prophecy of Teiresias, who promised him a happy old age and a peaceful death from the sea. According to a later legend, Telegonus, the son of Odysseus by Circe, was sent by her in search of his father. Cast ashore on Ithaca by a storm, he plundered the island to get provisions, and was attacked by Odysseus, whom he slew. The prophecy was thus fulfilled. Telegonus, accompanied by Penelope and Telemachus, returned to his home with the body of his father, whose identity he had discovered.

According to E. Meyer (Hermes, xxx. p. 267), Odysseus is an old Arcadian nature god identical with Poseidon, who dies at the approach of winter (retires to the western sea or is carried away to the underworld) to revive in spring (but see E. Rohde, *Rhein. Mus.*, l. p. 631). A more suitable identification would be Hermes. Mannhardt and others regard Odysseus as a solar or summer divinity, who withdraws to the underworld during the winter, and returns in spring to free his wife from the suitors (the powers of winter). A. Gercke ("Neue Jahrbücher für das klassische Altertum", xv. p. 331) takes him to be an agricultural divinity akin to the sun god, whose wife is the moon-goddess Penelope, from whom he is separated and reunited to her on the day of the new moon. His cult early disappeared; in Arcadia his place was taken by Poseidon. But although the personality of Odysseus may have had its origin in some primitive religious myth, chief interest attaches to him as the typical representative of the old seafaring race whose adventurous voyages educated and moulded the Hellenic race. The period when the character of Odysseus took shape among the Ionian bards was when the Ionian ships were beginning to penetrate to the farthest shores of the Black Sea and to the western side of Italy, but when Egypt had not yet been freely opened to foreign traders. But the ventures of Odysseus were a favourite subject in ancient art, in which he may usually be recognized by his conical sailor's cap.

See article by J. Schmidt in Roscher's *Lexikon der Mythologie* (where the different forms of the names and its etymology are fully discussed); O. Gruppe, "Griechische Mythologie", ii. pp. 624, 705-718; J. E. Harrison, *Myths of the Odyssey in Art and Literature* (1881), with annotated references to the Greek authors; E. Reisch, "Odysseus" (1905), l. p. 106; O. Seeck, *Gesch. des Untergangs der antiken Welt*, ii. p. 576; F. Gouguès, *Mammitso und l'Arcade orientale* (1898), according to whom Odysseus is an Arcadian chthonian divinity and Peneleus, who was at first a warrior goddess, identified with Athena, by S. Ettm, *Die gärtlichen Wurzeln bei den Griechen* (1902), who identifies Odysseus with one of the Dioscuri (*Odysseus = Πολύειδης*); V. Béard, *Les Phéniciens et l'Odyssee* (1902-1903), who regards the *Odyssey* as "the integration in a Greek Homer (home-coming) of a Semitic epic (going-forth)" by an Indian poet at the court of one of the Nebeli kings of Melitius. For an estimate of this work, the interest of which is mainly geographical, see *Classical Review* (April 1904) and *Quarterly Review* (April 1905). It consists of two large volumes, with 240 illustrations and maps.

**OEBEN, JEAN FRANÇOIS**, French 18th-century cabinet-maker, is believed to have been of German or Flemish origin; the date of his birth is unknown, but he was dead before 1767. In 1752, twenty years after Boullé's death, we find him occupying an apartment in the Louvre, submitted to him by Charles Joseph Boulle, who had occupied it when he himself became the king's pupil with Simon Oeben, presumably a relative, who signed a fine bureau in the Jones collection at the Victoria and Albert Museum. J. F. Oeben is also represented in that collection by a pair of inlaid corner-cupboards. These with a bureau and a chiffonier in the Garde Meuble in which bouquets of flowers are delicately inlaid in choice woods are his best-known and most admirable achievements. He appears to have worked extensively for the marquise de Pompadour by whose influence he was granted lodgings at the Gobelins and the title of "Ébéniste du Roi" in 1754. There he remained until 1760, when he obtained an apartment and workshops at the Arsenal. His work in marquetry is of very great distinction, but he would probably never have enjoyed so great a reputation had it not been for his connexion with the famous Bureau du Roi, made for Louis XV., which appears to have owed its inception to him, notwithstanding that it was not completed until some considerable time after his death and is signed by J. H. Riesener (c.1756 only). Documentary evidence under the hand of the king shows that it was ordered from Oeben in 1760, the year in which he moved to the Arsenal. The known work of Oeben possesses genuine grace and beauty; as craftsmanship it is of the first rank, and it is remarkable that, despite his Teutonic or Flemish origin, it is typically French in character.

**OECOLAMPADIUS, JOHN** (1482-1531), German Reformer, whose real name was Hussgen or Heussgen,1 was born at Weinsberg, a small town in the north of the modern kingdom of Württemberg, but then belonging to the Palatinate. He went to school at Weinsberg and Heilbronn, and then, intending to study law, he went to Bologna, but soon returned to Heidelberg and betook himself to theology. He became a zealous student of the new learning and passed from the study of Greek to that of Hebrew, taking his bachelor's degree in 1503. He became cathedral preacher at Basel in 1515, serving under Christopher von Uttenheim, the evangelical bishop of Basel. From the beginning the sermons of Oecolampadius centred in the Atonement, and his first reformatory zeal showed itself in a protest (*De reuiss pacchali, 1518*) against the introduction of humorous stories into Easter sermons. In 1520 he published his *Greek Grammar*. The same year he was asked to become preacher in the high church in Augsburg. Germany was then abaze with the questions raised by Luther's theses, and his introduction into this new world, when at first he championed Luther's position as it was, his anonymous *Confideindiss* (1526), seems to have compelled Oecolampadius to severe self-examination.

1 Changed to Haussech and then into the Greek equivalent.

**ODYSSEUS—OECOLAMPADIUS** I-1
tion, which ended in his entering a convent and becoming a monk. A short experience convinced him that this was not for him the ideal Christian life (“amīsi monachum, inveni Christianum”), and in February 1522 he made his way to Eberburg, near Creuznach, where he acted as chaplain to the little group of men holding the new opinions who had settled there under the leadership of Franz von Sickingen.

The second period of Oecolampadius’s life opens with his return to Basel in November 1522, as vicar of St Martin’s and (in 1523) reader of the Holy Scripture at the university. Lecturing on Isaiah he condemned current ecclesiastical abuses, and in a public disputation (20th of August 1523) was so successful that Erasmus writing to Zürich said “Oecolampadius has the upper hand amongst us.” He became Zwingli’s best helper, and after more than a year of earnest preaching and four public disputations in which the popular verdict had been given in favour of Oecolampadius and his friends, the authorities of Basel began to see the necessity of some reform. They began with the convents, and Oecolampadius was able to refrain in public worship on certain festival days from some practices he believed to be superstitious. Basel was slow to accept the Reformation; the news of the Peasants’ War and the inroads of Anabaptists prevented progress; but at last, in 1525, it seemed as if the authorities were resolved to listen to schemes for restoring the purity of worship and teaching. In the midst of these hopes and difficulties Oecolampadius married, in the beginning of 1526, Willibrandis Rosenblatt, the widow of Ludwig Keller, who proved to be non rixa vel garrula vel vaga, he says, and made him a good wife. After his death she married Capito, and, when Capito died, Bucer. She died in 1564.

In January 1528 Oecolampadius and Zwingli took part in the disputation at Berne which led to the adoption of the new faith in that canton, and in the following year to the discontinuance of the mass at Basel. The Anabaptists claimed Oecolampadius for their views, but in a disputation with them he dissociated himself from most of their positions. He died on the 24th of November 1531.

Oecolampadius was not a great theologian, like Luther, Zwingli or Calvin, and yet he was a trusted theological leader. With Zwingli he represented the Swiss views at the unfortunate conference at Marburg. His views on the Eucharist upheld the metaphorical against the literal interpretation of the word “body,” but he asserted that believers partook of the sacrament more for the sake of others than for their own, though later he emphasized it as a means of grace for the Christian life. To Luther’s doctrine of the ubiquity of Christ’s body he opposed that of the presence and activity of the Holy Spirit in the church. He did not minutely analyse the doctrine of predestination as Luther, Calvin and Zwingli did, contenting himself with the summary “Our Salvation is of God, our perdition of ourselves.” See I. J. Herzog, Leben Joh. Oecolampads u. die Reformation u. Kirche zu Basel (1843); K. R. Hagenbach, Johann Oecolampad u. Oswald Myconius, die Reformatoren Basels (1859). For other literature see W. Hadorn’s art. in Herzog-Hauck’s Realencyclopädie für die k. k. Staaten (1863) II. 805.

OECOLOGY, or Ecology (from Gr. οἰκολογία, house, and νόος, department of science), that part of the science of biology which treats of the adaptation of plants or animals to their environment (see PLANTS: Ecology).

OECUMENICAL (through the Lat. from Gr. οἰκουμένη, universal, belonging to the whole inhabited world, οἶκομενή sc. γῆ, οἶκων, to dwell), a word chiefly used in the sense of belonging to the universal Christian Church. It is thus specifically applied to the general councils of the early church (see COUNCIL). In the Roman Church a council is regarded as oecumenical when it has been summoned from the whole church under the presidency of the pope or his legates; the decrees confirmed by the pope are binding. The word has also been applied to assemblies of other religious bodies, such as the Oecumenical Methodist Conferences, which met for the first time in 1881. “Oecumenical” has also been the title of the patriarch of Constantinople since the 6th century (see Orthodox Eastern Church).

OECUS, the Latinized form of Gr. ὀεκύς, house, used by Vitruvius for the principal hall or saloon in a Roman house, which was used occasionally as a triclinium for banquets. When of great size it became necessary to support its ceiling with columns; thus, according to Vitruvius, the perfect style had four columns; in the Corinthian oecus there was a row of columns on each side, virtually therefore dividing the room into nave and aisles, the former being covered over with a semi-circular ceiling. The Egyptian oecus had a similar plan, but the aisles were of less height, so that clerestory windows were introduced to light the room, which, as Vitruvius states, presents more the appearance of a basilica than of a triclinium.

OEDIPUS (Οἰδίπος, Οἰδίπος, Οἰδίπος, from Gr. ὀδίπος, swelling, and τοῖς, foot, i.e. “the swollen-footed”) 1 in Greek legend, son of Laius, king of Thebes, and Jocasta (Locaste). Laius, having been warned by an oracle that he would be killed by his son, ordered him to be exposed, with his feet pierced, immediately after his birth. Thus Oedipus grew up ignorant of his parentage, and, meeting Laius in a narrow way, quarrelled with him and slew him. The country was ravaged by a monster, the Sphinx; Oedipus solved the riddle which it proposed to its victims, freed the country, and married his mother. In the play it is said that the gods disclosed the impety. (As Jocasta is called in Homer) hanged herself, and Oedipus lived as king in Thebes tormented by the Ereïnies of his mother. In the tragic poets the tale takes a different form. Oedipus fulfills an ancient prophecy in killing his father; he is the blind instrument in the hands of fate. The further treatment of the tale by Aeschylus is unknown. Sophocles describes in his Oedipus Tyrannus how Oedipus was resolved to pursue to the end the mystery of the death of Laius, and thus unravelled the dark tale, and in horror put out his own eyes. The sequel of the tale is told in the Oedipus Coloneus. Banished by his sons, he is tended by the loving care of his daughters. He comes to Attica and dies in the grove of the Eumenides at Colonus, in his death welcomed and pardoned by the fate which had pursued him throughout his life. In addition to the two tragedies of Sophocles, the legend formed the subject of a trilogy by Aeschylus, of which only the Seven against Thebes is extant; of the Phoenissae of Euripides; and of the Oedipus and Phoenissae of Seneca.

See A. Höfer’s exhaustive article in Roscher’s Lexicon der Mythologie; F. W. Schneidewin, Die Stiege von Oedipus (1852). D. Compari, Edipo e la mitologia comparata (1867); M. Bréal, “Le Mythe d’Edipe,” in Mélanges de mythologie (1878), who explains Oedipus as a personification of light, and his blinding as the disappoointment of the gods; H. D. R. Wace, Acta philologica Suecana, i, (Upsala, 1896) places the original home of the legend in Egyptian Thebes, and identifies Oedipus with the Egyptian god Seith, represented as the hippopothamus “with swollen foot,” which was said to kill its father in order to take its place with the mother. O. Crusius (Beiträge zur griechischen Mythologie, 1886, p. 21) sees in the marriage of Oedipus with his mother an agrarian myth (with special reference to Oed. Tyr. 1497), while H. Lichtenberger (Leipz. v. 1897) suggests that the episodes of the murder of his father and of his marriage are reminiscences of the overthrow of Cronus by Zeus and of the union of Zeus with his own sister.

Medieval Legends.—In the Golden Legend of Jacobus de Voragine (1263), and in the Legenda aurea, and in the more modern (15th century) and Arnaud Griban (15th century), the story of Oedipus is associated with the name of Judas. The main idea is the same as in the classical account. The Judas legend, however, never really entered into the charge, whereas that of Oedipus was handed orally and in written national tales (Albanian, Finnish, Cypriote). One incident (the incest unwittingly committed) frequently recurs in connexion with the life of Gregory the Great. The Theban legend, with its full working out in the Theban Martyrology and in Seneca, reappeared in the Roman de Thebes (the work of the unknown imitator of Benoît de Sainte-More). Oedipus is also the subject of an anonymous medieval romance (15th century), Le Roman d’Oedipe, fils de Lycurgus, in which the sphinx is depicted as a cunning and treacherous female, who was banished to the period of the Renaissance by the Roman and its imitations, which then fell into oblivion. Even to the present day the legend has

---

1 It is probable that the story of the piercing of his feet is a subsequent invention to explain the name, or is due to a false etymology (from ὀκύς), obíðros in reality meaning the "wise" (from ὀδύς), chiefly in reference to his having solved the riddle, the syllable τοῖς having no significance.
OEHLER—OELSNIITZ

OELSCHLÄGER [OELARIUS], ADAM (1600–1671), German traveller and Orientalist, was born at Aschersleben, near Magdeburg, in 1590 or 1600. After studying at Leipzig he became librarian and court mathematician to Duke Frederick III. of Holstein-Gottorp, and in 1633 he was appointed secretary to the ambassadors Philip Crusius, jurisconsult, and Otto Brüggemann or Brugman, merchant, sent by the duke to Moscovy and Persia in the hope of making arrangements by which his newly-founded city of Friedrichstadt should become the terminus of an overland silk-trade. This embassy started from Gottorp on the 22nd of October 1633, and travelled by Hamburg, Lübeck, Riga, Dorch (five months’ stay), Revel, Narva, Ladoga and Novgorod to Moscow (August 14, 1634). Here they concluded an advantageous treaty with Michael Romanov, and returned forthwith to Gottrup (December 14, 1634—April 7, 1635) to procure the ratification of this arrangement from the duke, before proceeding to Persia. This accomplished, they started afresh from Hamburg on the 22nd of October 1635, arrived at Moscow on the 29th of March 1636; and left Moscow on the 30th of June for Nizhny Novgorod, whether they had already sent agents (in 1634—1635) to prepare a vessel for their descent on the Volga. Their voyage down the great river and over the Caspian was slow and hindered by accidents, especially by grounding, as near Derbent on the 14th of November 1636; but at last, by way of Shemakha (three months’ delay here), Ardebl, Sultanish and Kavan, they reached the Persian court at Isfahan (August 3, 1637), and were received by the shah (August 16). Negotiations here were not as successful as at Moscow, and the embassy left Isfahan on the 21st of December 1637, and returned home by Rehst, Lenkoran, Astrakhan, Kazan, Moscov, &c. At Revel Oelschlager parted from his colleagues (April 13, 1639) and embarked direct for Lübeck. On his way he had made a chart of the Volga, and partly for this reason the tsar Michael wished him for consecutive service. On returning to Gottorp, Oelschlager became librarian to the duke, who also made him keeper of his Cabinet of Curiosities, and induced the tsar to excuse his (promised) return to Moscow. Under his care the Gottorp library and cabinet were greatly enriched in MSS., books, and oriental and other works of art: in 1651 he purchased, for this purpose, the collection of the Dutch scholar and physician, Bernard ten Broecke (“Paladus”). He died at Gottorp on the 22nd of February 1671.

It is by his admirable narrative of the Russian and the Persian legation (Beschreibung der muscovitischen und persischen Reise, Schleswig, 1647, and afterwards in several enlarged editions, 1656, &c.) that Oelschlager is best known, though he also published a history of Holstein-Tartarische Reich, ch. 14 (Tubingen, 1663), a famous catalogue of the Holstein-Gottorp cabinet (1666), and a translation of the Gulistan (Persianisches Rosenkohl, Schleswig, 1654), to which was appended a translation of the fables of La Fontaine. A French version of the Beschreibung was published by Abraham de Wicquefort (Voyages en Moscovie, Tartarie et Perse, par Adam Olearius, Paris, 1656), an English version was made by John Davies of Kidwelly (Travels of the Amor of Great Britain by Frederick Adam Oelschlaguer, Duke of Moscow and the King of Persia, London, 1662; 2nd ed., 1669), and a Dutch translation by Dieterius van Wageningen (Beschrijvingen van de nieuwe Persische ofte Orientaelsche Reysie, Utrecht, 1651). A German translation of the Russian sections appears in Check-Methode ou Fregen, ... di Moscovic, Viterbo and Rome, 1658). Paul Flemming the poet and J. A. de Mandelslo, whose travels to the East Indies are usually published with those of Oelschlager, accompanied the embassy. Under Oelschlager’s direction the celebrated globe of Gottorp (11 ft. in diameter) and armillary sphere were executed in 1654—1664; the globe was given to Peter the Great of Russia in 1713 by Duke Frederick’s grandson, Christian Augustus. Oelschlager’s unpublished works include Lexicon Persicum and several other Persian studies.

(C. R. B.)

OELSNIITZ, a town of Germany, in the kingdom of Saxony, on the Weisse Elster, 26 m. by rail S.W. of Zwickau. Pop. (1905) 13,066. It has two Evangelical churches, one of them being the old Gothic Jacobskirche, and several schools. There are various manufactories. Oelsniitz belonged in the 14th and 15th centuries to the margraves of Meissen, and later to the electors of Saxony. Near it is the village of Voigtsberg, with
the remains of a castle, once a residence of the governor (Vogt) of the Vogtland.

See Juhl, Chronik der Stadt Ötterlitz (1875).

**OELWEIN**, a city of Fayette county, Iowa, U.S.A., in the N.E. part of the state, about 132 m. N.E. of Des Moines. Pop. (1890) 830; (1900) 5142, of whom 780 were foreign-born; (1910 U.S. census) 6028. It is served by the Chicago, Rock Island & Pacific and the Chicago Great Western railways, the latter having large repair shops here, where four lines of its road converge. Oelwein was named in honour of its founder, August Oelwein, who settled here in 1872; it was incorporated in 1888, and chartered as a city in 1897.

**OENOMAUS**, in Greek legend, son of Ares and Harpina, king of Pisa in Elis and father of Hippodameia. It was predicted that he should be slain by his daughter's husband. His father, the god Ares-Hippius, gave him winged horses swift as the wind, and Oenomaus promised his daughter to the man who could outstrip him in the chariot race, hoping thus to prevent her marriage altogether. Pelops, by the treachery of Myrtius, the charioteer of Oenomaus, won the race and married Hippodameia. The defeat of Oenomaus by Pelops, a stranger from Asia Minor, points to the conquest of native Ares-worshipers by immigrants who introduced the new religion of Zeus.

See Died. Soc. iv. 73; Pausanias vii. 21, and elsewhere; Sophocles, Electra, 504; Hyginus, Fab. 84, 253. Fig. 33 in article GREEK ART represents the preparations for the chariot race.

**OENONE**, in Greek legend, daughter of the river-god Kebren and wife of Paris. Possessing the gift of divination, she warned her husband of the evils that would result from his journey to Greece. The sequel was the rape of Helen and the Trojan War. Just before the capture of the city, Paris, wounded by Philoctetes with one of the arrows of Heracles, sought the aid of the deserted Oenone, who had told him that she alone could heal him if wounded. Indignant at his faithlessness, she refused to help him, and Paris returned to Troy and died of his wound. Oenone soon repented and hastened after him, but finding that she was too late to save him slew herself with grief at the sight of his dead body. Ovid (Heroides, 5) gives a pathetic description of Oenone's grief when she found herself deserted.

**OERLAMS**, the name (said to be a corruption of the Dutch Oerlonders) for a Hottentot tribal group living in Great Namqualand. They came originally from Little Namqualand in Cape Colony. They are of very mixed Hottentot-Bantu blood.

**OESL** (in Estonian Kure-saar or Saare-ma), a Russian island in the Baltic, forming with Worms, Mohn and Runó, a district of the government of Livonia, and lying across the mouth of the Gulf of Riga, 106 m. N.W. of the city of Riga. It has a length of 45 m., and an area of 1010 sq. m. The coasts are bold and steep, and, especially towards the north and west, form precipitous limestone cliffs. Like those of Scitland, the Oesl ponies are small, but prized for their spirit and endurance. The population, numbering 30,560 in 1870 and 66,000 in 1900, is mainly Protestant in creed, and, with the exception of the German nobility, clergy and some of the townsfolk, Estonian by race. The chief town, Arensburg, on the south coast, is a place of music and industry, with summer sea-bathing, mud baths and a trade in grain, potatoes, whisky and fish. In 1227 Oesl was conquered by the Knights of the Sword, and was governed by its own bishops till 1567, when it passed into the hands of the Danes. By them it was surrendered to the Swedes by the peace of Brömsebro (1645), and, along with Livonia, it was united in Russia in 1721.

**OBESPHAGUS** (Gr. ὀβεσφάγης I will carry, and φάγεω, to eat), in anatomy, the gullet; see Alimentary Canal for comparative anatomy. The human oesophagus is peculiarly liable to certain accidents and diseases, due both to its function as a tube to carry food to the stomach and to its anatomical situation (see generally Digestive Organs). One of the commonest accidents is the lodgment of foreign bodies in some part of the tube. The situations in which they are arrested vary with the nature of the body, whether it be a coin, fishbone, toothpaste or a portion of food. An impacted substance may be removed by the oesophageal forceps, or by a coin-catcher; if it should be impossible to draw it up it may be pushed down into the stomach. When it is in the stomach a purgative should never be given, but soft food such as porridge. Should gastric symptoms develop it may have to be removed by the operation of gastrotomy. Charring and ulceration of the oesophagus may occur from the swallowing of corrosive liquids, strong acids or alkalies, or even of boiling water. Stricture of the oesophagus is a closing of the tube so that neither solids nor liquids are able to pass down into the stomach. There are three varieties of stricture; spasmotic, fibrous and malignant. Spasmotic stricture usually occurs in young hysterical women; difficulty in swallowing is complained of, and a bougie may not be able to be passed, but under an anaesthetic will slip down quite easily. Fibrous stricture is usually situated near the commencement of the oesophagus, generally just behind the cricoid cartilage, and usually results from swallowing corrosive fluids, but may also result from the healing of a syphilitic ulcer. Occasionally it is congenital. An ordinary stricture is treated by bougies. Occasionally division of a fibrous stricture has been practised, or a Symond's tube inserted. Mikulicz recommends dilatation of the stricture by the fingers from inside after an incision into the stomach or a permanent gastric fistula may have to be made. Malignant strictures are usually epitheliomatous in structure, and may be situated in any part of the oesophagus. They nearly always occur in males between the ages of 40 and 70 years. An X-ray photograph taken after the patient has swallowed a preparation of bismuth will show the situation of the growth, and Killian and Brüning have introduced an instrument called the oesophagoscope, which makes direct examination possible. The remedy of constant dilatation by bougies must not be attempted here, the walls of the oesophagus being so softened by disease and ulceration that severe haemorrhage or perforation of the walls of the tube might take place. The patient should be fed with purely liquid and concentrated nourishment in order to give the oesophagus as much rest as possible, or if the stricture be rectal feeding may be necessary. Symond's method of tube-bag is well borne by some patients, the tube having attached to it a long string which is secured to the cheek or ear. The most satisfactory treatment, however, is the operation of gastrostomy, a permanent artificial opening being made into the stomach through which the patient can be fed.

**OETA** (mod. Kotovutha), a mountain to the south of Thessaly, in Greece, forming a boundary between the valleys of the Spercheius and the Boeotian Cephissus. It is an offshoot of the Pindus range, 7080 ft. high. In its eastern portion, called Callidromus, it comes close to the sea, leaving only a narrow passage known as the famous pass of Thermopylae (q.v.). There was also a high pass to the west of Callidromus leading over into the upper Cephissus valley. In mythology Oeta is chiefly celebrated as the scene of the funeral pyre on which Heracles burnt himself before his admission to Olympus.

**OETINGER, FRIEDRICH CHRISTOPH** (1702–1782), German divine and theologian, was born at Goppingen on the 6th of May 1702. He studied theology at Tübingen (1722–1728), and was much impressed by the works of Jakob Böhme. On the completion of his university course, Oetinger spent some years in travel. In 1730 he visited Count Zinzendorf at Herrnhut, remaining there some months as teacher of Hebrew and Greek. During his travels, in his eager search for knowledge, he made the acquaintance of mystics and separatists, Christians and learned Jews, theologians and physicians alike. At Halle he studied medicine. After some delay he was ordained to the ministry, and held several pastorates. While pastor (from 1746) at Waldorf near Berlin, he studied alchemy and made many experiments, his idea being to use his knowledge for symbolic purposes. These practices exposed him to the attacks of persons who misunderstood him. "My religion," he once said, "is the parallelism of Nature and Grace." Oetinger translated Swedenborg's philosophy of heaven and earth, and added notes
of his own. Eventually (1766) he became prelate at Murrhardt, where he died on the 10th of February 1782.

Oetinger's autobiography was published by J. Hammer in 1845. He published about seventy works, in which he expanded his theosiphic views. A collected edition, Sämtliche Schriften (1st section, Homiletische Schriften, 5 vols., 1858–1866; 2nd section, Theosophische Werke, 6 vols., 1858–1863), was prepared by K. F. C. Ehrmann, who also wrote Oetinger's Leben und Briefe (1840), also C. A. Aubelen, Die Theosophie Friedr. Ch. Oetinger's (1847; 2nd ed., 1859), and Herzog, Friedrich Christoph Oetinger (1902).

OEFENBACH, a town and watering-place of Germany, in the Prussian province of Westphalia, on the Werre, situated just above its confluence with the Weser, 9 m. W. from Minden by the main line of railway from Hanover to Cologne, with a station on the Löhme-Hameln line. Pop. (1903) 3894.

The place, which was formerly called Rheine, owes its development to the discovery in 1830 of its five famous salt springs, which are heavily charged with carbonic acid gas. The waters are used both for bathing and drinking, and are particularly efficacious for nervous disorders, rheumatism, gout and feminine complaints.

OFFA, the most famous hero of the early Angli. He is said by the Anglo-Saxon poem Widsith to have ruled over Angel, and the poem refers briefly to his victorious single combat, a story which is related at length in Weenung's Chronicle. The sires of the Saxons and the Franks are said to have been inoffensive during his early years, and to have only recovered his speech when his aged father Wermund was threatened by the Saxons, who insolently demanded the cession of his kingdom. Offa undertook to fight against both the Saxon king's son and a chosen champion at once. The combat took place at Emondsburg on an island in the Elder, and Offa succeeded in killing both his opponents. According to Widsith Offa's opponents belonged to a tribe or dynasty called Myrgingas, but both accounts state that he won a great kingdom as the result of his victory. A somewhat corrupt version of the same story is preserved in the Vitae duorum Offarum, where, however, the scene is transferred to England. It is very probable that the Offa whose marriage with a lady of murderous disposition is mentioned in Beowulf is the same person; and this story also appears in the Vitae duorum Offarum, though it is erroneously told of a later Offa, the famous king of Mercia. Offa of Mercia, however, was a descendant in the 12th generation of Offa, king of Angel. It is probable that there is some other evidence that the early Offa lived in the latter part of the 4th century.

See H. M. Chadwick, Origin of the English Nation (Cambridge, 1897), where references to the original authorities will be found.

OFFA (d. 796), king of Mercia, obtained that kingdom in a.d. 757, after driving out Beornred, who had succeeded a few months earlier on the murder of Æthelbad. He traced his descent from Pwyba, the father of Penda, through Eowa, brother of that king, his own father's name being Thingfirth. In 770 he was at war with Cynwulf of Wessex from whom he wrested Bensington. It is not unlikely that the Thames became the boundary of the two kingdoms about this time. In 787 the power of Offa was displayed in a synod held at a place called Caeclthrith. He deprived Jænberht, archbishop of Canterbury, of several of his suffragan sees, and assigned them to Lichfield, which, with the leave of the pope, he constituted as a separate archbishopric under Hygeberht. He also took advantage of this meeting to have his son Egfrith consecrated as his colleague, and that prince subsequently signed charters as Rex. In 794 Offa considered the chance of Berhtic of Wessex by giving him his daughter Eadburg in marriage. In 794 he appears to have caused the death of Æthelberht of East Anglia, though some accounts ascribe the murder to Cynethryth, the wife of Offa. In 790 Offa died after a reign of thirty-nine years and was succeeded by his son Egfrith. It is customary to ascribe to Offa a policy of limited scope, namely the establishment of Mercia in a position equal to that of Wessex and of Northumbria. This is supposed to be illustrated by his measures with regard to the see of Lichfield. It cannot be doubted, however, that at this time Mercia was a much more formidable power than Wessex. Offa, like most of his predecessors, probably held a kind of supremacy over all kingdoms south of the Humber. He seems, however, not to have been contented with their affection, and to have entertained the design of putting an end to the dependence of the kingdoms. At all events we hear of no kings of the Hwice after about 790, and the kings of Sussex seem to have given up the royal title about the same time. Further, there is no evidence for any kings in Kent from 784 until after Offa's death. To Offa is ascribed by Asser, in his life of Alfred, the great fortification against the Welsh which is still known as "Offa's dyke." It stretched from sea to sea and consisted of a wall and a rampart. An account of his Welsh campaigns is given in the Vitae duorum Offarum, but it is difficult to determine how far the stories there given have an historical basis.

OFFAL, refuse or waste stuff, the "off fall," that which falls off (cf. Dutch afval, Ger. Abfall). The term is applied especially to the waste parts of an animal that has been slaughtered for food, to putrid flesh or carrion, and to waste fish, especially the smaller kinds which are taken in the nets with the larger and better fish, and are thrown away by the fisherman.

An offal is also a term applied to grain "offal" is used of grains too small or light for use for flour, and also in flour milling of the husk or bran of wheat with a certain amount of flour attached, sold for feeding beasts (see Flour).

OFFENBACH, JACQUES (1819–1886), French composer of opéra bouffe, was born at Cologne, of German Jewish parents, on the 21st of June 1819. His talent for music was developed at a very early age; and in 1833 he was sent to Paris to study the violoncello at the conservatoire, where, under the care of Professor Vaslin, he became a fairly good performer. In 1834 he became a member of the orchestra of the Opéra Comique; and he turned his opportunities to good account, so that eventually he was made conductor at the Théâtre Français. There, in 1848, he made his first success as a composer in the Chanson de Fortune in Alfred de Musset's play Le Chandelier. From this time forward his life became a ceaseless struggle for the attainment of popularity. His power of production was prodigious. In 1847, his Princesse de Navarre, was produced at the Opéra Comique in 1853. This was followed by a crowd of dramatic pieces of a light character, which daily gained in favour with Parisian audiences, and eventually effected a complete revolution in the popular taste of the period. Encouraged by these early successes, Offenbach boldly undertook the delicate task of entirely remodelling both the form and the style of the light musical pieces which had so long been welcomed with acclamation by the frequenters of the smaller theatres in Paris. With this purpose in view he obtained a lease of the Théâtre Comte in the Passage Choiseul, reopened it in 1855 under the title of the Bouffes Parisiens, and night after night attracted crowded audiences by a succession of brilliant, humorous trifles. Ludovic Halévy, the librettist, was associated with him from the first, but still more after 1860, when Halévy obtained Henri Meilhac's collaboration (see Halévy). Beginning with Les Deux Aveugles et Le Violonois, the series of Offenbach's operettas was rapidly continued, until in 1867 its triumph culminated in La Grande Duchesse de Grolfiest, perhaps the most popular opéra bouffe that was ever written, excepting even his Orphée aux enfers, produced in 1858. From this time forward the success of Offenbach's pieces became an absolute certainty, and the new form of opéra bouffe, which he had gradually endowed with as much consistency as it was capable of assuming, was accepted as the only one worth cultivating. It found imitators in Lecoq and other aspirants of a younger generation, and Offenbach's works found their way to every town in Europe in which a theatre existed. Tuneful, gay and exhilarating, their want of refinement formed no obstacle to their popularity, and perhaps even contributed to it. In 1866 his ownconnexion with the Bouffes Parisiens ceased, and he wrote for various
theatres. In twenty-five years Offenbach produced no less than sixty-nine complete dramatic works, some of which were in Sadie's or even in four acts. Among the latest of these were *Le Docteur Ox*, founded on a story by Jules Verne, and *La Botte au tail*, both produced in 1877, and *Madame Favart* (1879). Offenbach died at Paris on the 5th of October 1880.

**OFFENBACH**, a town of Germany, in the grand-duchy of Hesse, on the left bank of the Main, 5 m. S.E. of Frankfurt-on-Main, with which it is connected by the railway to Bebra and by a local electric line. Pop. (1905) 58,806, of whom about 20,000 were Roman Catholics and 14,000 Jews. The most interesting building in the town is the Renaissance château of the counts of Isenburg. Offenbach is the principal industrial town of the duchy, and its manufactures are of the most varied description. Its characteristic industry, however, is the manufacture of portfolios, pocket-books, albums and other fancy goods in leather. The earliest mention of Offenbach is in a document of 970. In 1486 it came into the possession of the counts of Isenburg, who made it their residence in 1685, and in 1816, when their lands were mediatized, it was assigned to Hesse. It owes its prosperity in the first place to the industry of the French Protestant refugees who settled here at the end of the 17th, and the beginning of the 18th century, and in the second place to the accession of Hesse to the German Zollverein in 1828.

See Jöst, *Offenbach am Main in Vergangenheit und Gegenwart* (Offenbach, 1901); Hager, *Die Lederverwirindustrie in Offenbach* (Karlsruhe, 1905).

**OFFENBURG**, a town of Germany, in the grand-duchy of Baden, 27 m. by rail S.W. of Baden, on the river Kinzig. Pop. (1905) 15,434. It contains a statue of Sir Francis Drake, a mark of honour due to the fact that Drake is sometimes regarded as having introduced the potato into Europe. The chief industries of the town are the making of cotton, linen, hats, malt, machinery, tobacco, and cigars and glass. Offenburg is first mentioned about 1100. In 1223 it became a town; in 1248 it passed to the bishop of Speyer; and in 1280 it became an imperial free city. Soon, however, this position was lost, but it was regained about the middle of the 16th century, and Offenburg remained a free city until 1802, when it became part of Baden. In 1632 it was taken by the Swedes, and in 1658 it was destroyed by the French.

See Walter, *Kurzer Abriss der Geschichte der Reichsstadt Offenburg* (Offenburg, 1896).

**OFFERTORY** (from the ecclesiastical Late *offerentrum*, Fr. *offertoire*, a place to which offerings were brought), the alms of a congregation collected in church, or at any religious service. Offertory has also a special sense in the services of both the English and Roman churches. It forms in both that part of the Communion service appointed to be said or sung, during the collection of alms, before the elements are consecrated. In music, an offertory is the vocal or instrumental setting of the offertory sentences, or a short instrumental piece played by the organ while the collection is being made.

**OFFICE** (from Lat. *officium*, “duty,” “service,” a shortened form of *opus*, from *facere*, “to do,” and either the stem of *opus*, “wealth,” “aid,” or *opus*, “work”), a duty or service, particularly the special duty cast upon a person by his position; also a ceremonial duty, as in the rites paid to the dead, the “last offices.” The term is thus especially used of a religious service, the “daily office” of the English Church or the “divine office” of the Roman Church (see Breviary). It is also used in this sense of a service for a particular occasion, as the Office for the Visitation of the Sick, &c. From the sense of duty or function, the word is transferred to the position or place which lays on the holder or occupier the performance of such duties. This leads naturally to the use of the word for the buildings or the separate rooms in which the duties are performed, and for the staff carrying on the work or business in such offices. In the Roman curia the department of the Inquisition is known as the Holy Office, in full, the Congregation of the Holy Office of the Inquisition (see Inquisition and Curia Romana).

**Offices of Profit.**—The phrase “office of profit under the crown” is used with a particular application in British parliamentary practice. The holders of such offices of profit have been subject in regard to the occupation of seats in the House of Commons to certain disabilities which were in their origin due to the fear of the undue influence exercised by the crown during the constitutional struggles of the 17th century. Attempts to deal with the danger of the presence of “place-men” in the House of Commons were made by the Place Bills introduced in 1672–1673, 1694 and 1743. The Act of Settlement 1700 (§ 3) laid it down that no person who has an office or place of profit under the king or receives a pension from the crown shall be capable of serving as a member of the House of Commons. This drastic clause, which would have had the disastrous effect of entirely separating the executive from the legislature, was repealed and the basis of the present law was laid down in 1706 by 6 Anne (c. 41). This first disqualifies (§ 24) from membership all holders of “new offices,” i.e. those created after October 1705; secondly (§ 25) it renders void the election of a member who shall accept any office of profit other than “new offices” but allows the member to stand for re-election. The disqualification attaching to many “new offices” has been removed by various statutes, and by § 22 of the Reform Act 1867 the necessity of re-election is avoided when a member, having been elected subsequent to the acceptance of any office named in a schedule of that act, is transferred to any other office in that schedule. The rules as to what offices disqualify from membership or render re-election necessary are exceedingly complicated, depending as they do on a large number of statutes (see Erskine May, *Parliamentary Practice*, 11th ed., pp. 632–645, and Rogers, *On Elections*, vol. ii., 1906). The old established rule that a member, once duly elected, cannot resign his seat is evaded by the acceptance of certain minor offices (see chilltern Hundreds).

**OFFICERS.** Historically the employment of the word “officer” to denote a person holding a military or naval command as representative of the state, and not as deriving his authority from his own powers or privileges, marks an entire change in the character of the armed forces of civilized nations. Originally signifying an official, one who performs an assigned duty (Lat. *officium*), an agent, and in the 15th century actually meaning the subordinate of such an official (even to-day a constable is so called), the word seems to have acquired a military significance late in the 16th century. It was at this time that armies, though not yet “standing,” came to be constituted almost exclusively of professional soldiers in the king’s pay. Mercenaries, and great numbers of mercenaries, had always existed, and their captains were not feudal magnates. But the bond between mercenaries and their captains was entirely personal, and the bond between the captain and the sovereign was of the nature of a contract. The non-mercenary portion of the older armies was feudal in character. It was the lord and not a king’s officer who commanded it, and he commanded in virtue of his rights, not of a warrant or commission.

European history in the late 15th century is the story of the victory of the crown over the feudalatories. The instrument of the crown was its army, raised and commanded by its deputies. But these deputies were still largely soldiers of fortune and, in the higher ranks, feudal personages, who created the armies themselves by their personal influence with the would-be soldier or the unemployed professional fighting man. Thus the first system to replace the obsolete combination of feudalism and “free companies” was what may be called the proprietary system. Under this the colonel was the proprietor of his regiment, the captain the proprietor of his company. The king accepted them as his officers, and armed them with authority to raise men, but they themselves raised the men as a rule from experienced soldiers who were in search of employment, although, like 1

1 This section also disqualifies colonial governors and deputy governors and holders of certain other offices.

2 At sea the relatively clear partition of actual duties amongst the authorities of a ship brought about the adoption of the term “officer” somewhat earlier.
Falstaff, some captains and colonels "misused the King’s press damnably." All alike were most rigorously watched lest by showing imaginary men on their pay-sheets they should make undue profits. A "mustering" was the production of a number of living men on parade corresponding to the number shown on the pay-sheets. An inspection was an inspection not so much of the efficiency as of the numbers and the accounts of units. A full account of these practices, which were neither more nor less prevalent in England than elsewhere, will be found in J. W. Fortescue’s *History of the British Army*, vol. i. So faithfully was the custom observed of requiring the showing of a man for a man’s pay, that the grant of a special allowance to officers administering companies was often made in the form of allowing them to show imaginary John Does and Richard Roés on the pay-sheets.

The next step was taken when armies, instead of being raised for each campaign and from the qualified men who at each recruiting time offered themselves, became "standing" armies fed by untrained recruits. During the late 17th and the 18th centuries the crown supplied the recruits, and also the money for maintaining the forces, but the colonels and captains retained in a more or less restricted degree their proprietorship.

Thus, the profits of military office without its earlier burdens were in time of peace considerable; and an officer’s commission had a saleable value. The practice of passing over the selling commissions was a natural consequence, and this continued long after the system of proprietary regiments and companies had disappeared. In England “purchase” endured until 1783, nearly a hundred years after it had ceased on the continent of Europe and more than fifty after the clothing, feeding and payment of the soldiers had been taken out of the colonels’ hands. The purchase system, it should be mentioned, did not affect artillery and engineer officers, either in England or in the rest of Europe. These officers, who were rather semi-civil than military officials until about 1715, executed an office rather than a command — superintended gun-making, built fortresses and so on. As late as 1780 the right of a general officer promoted from the Royal Artillery to command troops of other arms was challenged. In its original form, therefore, the proprietary system was a most serious bar to efficiency. So long as war was chronic, and self-trained recruits were forthcoming, it had been a good working method of devolving responsibility. But when drill and the handling of arms became more complicated, and, above all, when the supply of trained soldiers became too great, the old system disappeared, the colonels’ and captains’ hands, and, as the individual officer had now nothing to offer the crown but his own potential military capacity (part of which resided in his social status, but by no means all), the crown was able to make him, in the full sense of the word, an officer of itself. This was most fully seen in the reorganization of the French army by Louis XIV. and Louvois. The colonels and captains of horse and foot remained proprietary officers in the hands of the nobles but these offices were sinecures or almost sinecures. The colonels, in peace at any rate, were not expected to do regimental duty. They were at liberty to make such profits as they could make under a stringent inspection system. But they were expected to be the influential figure-heads of their regiments and to pay large sums for the privilege of being proprietors. This classification of officers into two bodies, the poorer which did the whole of the work, and the richer upon which the holding of a commission conferred an honour which birth or wealth did not confer, marks two very notable advances in the history of army organization, the professionalization of the officer and the creation of the prestige attaching to the holder of a commission because he holds it and not for any extraneous reason.

The distinction between working and quasi-honorary officers was much older, of course, than Louvois’s reorganization. Moreover it extended to the highest ranks. About 1600 the "general" of a European army was always a king, prince or nobleman. The lieutenant-general, by custom the commander of the cavalry, was also, as a rule, a noble, in virtue of his command of the aristocratic arm. But the commander of the foot, the "sergeant-major general" or "major-general," was invariably a professional soldier. It was his duty to draw up the army (not merely the foot) for battle, and in other respects to act as chief of staff to the general. In the infantry regiment, the "sergeant-major" or "major" was second-in-command and adjutant combined. Often, if not always, he was promoted from amongst the lieutenants and not the (proprietary) captains. The lieutenants were the backbone of the army.

Seventy years later, on the organization of the first great standing army by Louvois, the "proprietors," as mentioned above, were reduced to a minimum both in numbers and in military importance. The word "major" in its various meanings had come, in the French service, to imply staff functions. Thus the sergeant-major of infantry became the "adjutant-major." The sergeant-major-general, as commander of the foot, had disappeared and given place to numerous lieutenant-generals and "brigadiers," but as chief of the staff he survived for two hundred years. As late as 1870 the chief of staff of a French army bore the title of "the major-general."

Moreover a new title had come into prominence, that of "marshal" or "field marshal." This marks one of the most important points in the evolution of the military officer. His classification by rank and not by the actual uniform he holds. In the 16th century an officer was a lieutenant of, not in, a particular regiment, and the higher officers were general, lieutenant-general and major-general of a particular army. When their army was disbanded they had no command and possessed therefore no rank—except of course when, as was usually the case, they were colonels of permanent regiments or governors of fortresses. Thus in the British army it was not until late in the 18th century that general officers received any pay as such. The introduction of a distinctively military rank of "marshal" or "field marshal," which took place in France and the empire in the first years of the 17th century, meant the establishment of a list of general officers, and the list spread downwards through the various regimental ranks, as the close proprietary system broke up, until it became the general army list of an army of to-day. At first field marshals were merely officers of high rank and experience, eligible for appointment to the offices of general, lieutenant-general, &c., in a particular army. On an army being formed, the list of field marshals was drawn upon, and the necessary number appointed. Thus an army of Gustavus Adolphus’s time often included 6 or 8 field marshals as subordinate general officers. But soon armies grew larger, more mobile and more flexible and more general officers were needed. Thus fresh grades of general arose. The next rank below that of marshal, in France, was that of lieutenant-general, which had formerly implied the second-in-command of an army, and a little further back in history the king’s lieutenant-general or military viceroy. Below the lieutenant-general was the maréchal de camp, the heir of the sergeant-major-general. In the imperial service the ranks were field marshal and lieutenant field marshal (both of which survive to the present day) and major-general. A further grade of general officer was created by Louis XIV., that of brigadier, and this completes the process of evolution, for the regimental system had already provided the lower titles.

The ranks of a modern army, with slight variations in the names, are therefore as follows:

1 Field marshal: in Germany, Generalfeldmarschall; in Spain captain-general; in France (though the rank is in abeyance) marshal; in England, the rank of "marshal" is now merely honorary, there being rather few in number nor so restricted to the highest commands as are marshals elsewhere. In Germany a new rank, "colonel-general"

2 The title was, of course, far older.

3 In England, until after Marlborough’s death, rank followed command and not vice versa. The first field marshals were the Duke of Argyll and the Earl of Cadogan. Marlborough’s title, or rather office, was that of captain-general.
(Generalsberich), has come into existence—or rather has been revived—
of late years. Most of the holders of this rank have the honorary style of general-field-marshall.

(b) General: in Germany and Russia, "general of infantry," "general of cavalry," "general of artillery." In Austria general of infantry is the highest title of Feldzeugmeister (ordnance-master) up to 1909, but the grade of general of infantry was created in that year, the old title being now restricted to generals of artillery. In France the highest grade of general officers is that of lieutenant-general, which is the grade of full "general" which has only been held by Washington, Grant, Sherman and Sheridan.

(c) Lieutenant-general (except in France): in Austria the old title of lieutenant-colonel is retained. In the United States army the title "lieutenant-general," except within recent years, has been almost as rare as "general." Winfield Scott was a brevet lieutenant-general. The substantive rank was revived for Grant when he was placed in command of the Union Army in 1864. It was abolished as an ordinary rank in 1907.

(d) Major-general (in France, general of brigade): this is the highest grade normally found in the United States Army, generals and lieutenant-generals being promoted for special service only.

(e) Field-generals which have united States and (as a temporary rank only) in the British services.

The above are the five grades of higher officers. To all intents and purposes, no nation has more than four of these five ranks, while France and the United States, the great republics, have only two. The correspondence between rank and functions cannot be exactly laid down, but in general an officer of the rank of lieutenant-general commands an army corps and a major-general a division. Brigades are commanded by major-generals, brigadier-generals or colonels. Armies are as a rule commanded by field marshals or full generals. In France generals of division command divisions, corps, armies and groups of armies.

The above are classed as general officers. The "field officers" (French officiers supérieurs, German Stabsoffiziere) are as follows:

(a) Colonel:—This rank exists in its primitive significance in every army. It denotes a regimental commander, or an officer of corresponding status on board a ship. In Great Britain, with the "linked battalion" system, regiments of infantry do not work as units, and the executive command of battalions, regiments of cavalry and brigades of field artillery is in the hands of lieutenants-colonels. Colonels of British regiments who are quasi-honorary (though no longer proprietary) chiefs are royal personages or general officers. Colonels in active employment as such are either on the staff, commanders of brigades or corresponding units, or otherwise extra-regimentally employed.

(b) Lieutenant-colonel: in Great Britain the commanding officer of a unit. Elsewhere, where the regiment and not the battalion is the executive unit, the lieutenant-colonel sometimes acts as regiments, sometimes as commanding major of battalions. In Russia all the battalion leaders are lieutenant-colonels.

(c) Major.—This rank does not exist in Russia, and in France is replaced by chef de bataillon or chef d'escadron, colloquially commanded by the word "lieutenant-colonel" in the French army. The latter is the character of the ancient "sergeant-major," as a second in command with certain administrative duties. The junior majors command companies. In the cavalry the majors, other than the second-in-command, command squadrons; in the field artillery, majors, batteries for field-generals which have united States and (as a temporary rank only) in the British services.

Last the "company officers" (called in France and Germany subaltern officers) are as follows:

(a) Captain (Germany and Austria, Hauptmann, cavalry Rittmeister): in the infantry of all countries, the company commander. In Russia there is a lower grade of captain called "first capt.," and "second captain," in all countries except Great Britain captains command squadrons and batteries. Under the captain, with such commands and powers as are delegated to them, are the subalterns, usually graded as—

1 Infantry, lowest scale, other arms and branches higher, often considerably higher.

It must be noted that in France and Germany the major is a battalion commander, corresponding to the British lieutenant-colonel. But the significance of this table can only be realized when it is remembered that promotion is rapid in the British army and very slow in the others. The senior Oberleutnants of the German army are second-captains, i.e. 57 to 38 years of age; the senior French lieutenants, 47 to 38 years. In 1907 the average age of the younger majors 45 years of age. As another illustration, the captain's maximum pay in the French army, £10 per annum less than a British captain's, is only given after 12 years' service in that rank, i.e. to a man of at least twenty years' service.

The corresponding times for British regular officers in 1905 (when the effects of rapid promotions during the South African War were still felt) were 6 to 7½ years from first commission to promotion to captain, and 14 to 20 years from first commission to promotion to major. In 1908, under more normal conditions, the times were 7 to 8½ years to captain, 15 to 20 to major. In the Royal Engineers and the Indian army a subaltern is automatically promoted captain on completing 9 years' commissioned service, and a captain similarly promoted major after 18 years.

The process of development in the case of naval officers (see Navy) presents many points of similarity, but also considerable differences. For from the first the naval officer could only offer to serve on the king's ship: he did not build a ship as a colone raised a regiment, and thus there was no proprietary system. On the other hand the naval officer was even more of a simple office-holder than his comrade ashore. He had no rank apart from that which he held in the ship and when the ship was commissioned the officers as well as the crew were disbanded. One feature of the proprietary system, however, appears in the navy organization: there was a marked distinction between the captain and the lieutenant who led the combatants and the master and the master's mate in the interests, and instead of remaining in the condition, so to speak, of distinguished passengers, until ultimately selected by the "levelling up" of the working class of officers, the lieutenants and captains were (in England) required to educate themselves thoroughly in the subjects of the sea officer's profession. When this process had gone on for two generations, that is, about 1670, the formation of
permanent staff of naval officers was begun by the institution of half-pay for the captains, and very soon afterwards the methods of admission and early training of naval officers were systematized.

The ranks in the British Royal Navy are shown with the relative ranks of the army in the following table (taken from King's Regulations), which also gives some idea of the complexity of the non-combatant branches of naval officers.

**Training of British Army Officers.**—This may be conveniently divided into two parts: (I.) that which precedes the appointment to a commission; (II.) that which succeeds it.

1. Omitting those officers who obtain their commissions from the ranks, the training which precedes the appointment to a commission is subdivided into: (a) General Education; (b) Technical Instruction.

(a) **General Education.**—A fairly high standard of education is considered essential. Candidates from universities approved by the Army Council must have resided for three academic years at their university, and have taken a degree in any subject or group of subjects other than Theology, Medicine, Music and Commerce. A university candidate for a commission in the Royal Artillery must further be qualified in Mathematics. The obtaining of first-class honours is considered equivalent to one year's extra service in the army, and an officer can count that year for calculating his service towards his pension. University candidates are eligible for commissions in the Cavalry, Royal Artillery, Infantry, Indian Army and Army Service Corps. For other branches of the service special regulations are in force.

Those candidates who have not been at a university are examined by the Civil Service Commissioners as to their educational qualifications. This examination is competitive in so far that vacancies at the Royal Military College at Sandhurst (for Cavalry, Infantry and Army Service Corps), or the Royal Military Academy at Woolwich (for Engineers and Artillery), go to those who pass highest, if physically fit. Before presenting himself for this examination, the candidate must produce a "leaving certificate" from the school at which he was educated, showing that he already possesses a fair knowledge of the subjects of examination. Candidates who fail to secure admission to these institutions, but satisfy the examiners that they are sufficiently well educated, can obtain commissions in the Special Reserve.

Candidates for commissions in the Royal Army Medical Corps and the Army Veterinary Corps are not required to pass an educational examination, the ordinary course of medical or veterinary education being deemed sufficient, but the Army Council may reject a candidate who shows any deficiency in his general education.

Officers of the Colonial military forces wishing to obtain commissions in the British Army must either produce a school or college "leaving certificate" or pass an examination held by the Army Qualifying Board, or must show that they have passed one of certain recognized examinations.

(b) **Technical Instruction.**—In addition to general educational attainments, a fair knowledge of technical matters is expected from candidates.

For Cavalry, Infantry, Royal Engineers, Royal Artillery and Army Service Corps, an examination must be passed in administration and organization; military history, strategy and tactics; military
topography, engineering and law. In addition, the following conditions must be complied with: (1) University candidates are required to be members of the Senior Division of the Officers' Training Corps (see United Kingdom: Army) should there be a university in their university, and the examination is further required to be attended for six weeks to a Regular unit during their residence at the university. If there is no Officers' Training Corps at their university, the candidate is required to attend a Regular unit for a minimum of six weeks. Admission to any examination subject is further regulated by the Royal Engineers and the Royal Army Medical Corps. The final examination in military subjects is competitive.

Cadets of the Royal Military College are instructed in the following additional subjects: sanitation, French or German (or both), riding and horse management, musketry, physical training, and signalling. Hindustani is the primary language of instruction. Cadets who pass highest in the final examination for commissions are as a rule appointed to the Royal Engineers, the remainder to the Royal Artillery, Royal Engineers, or the Royal Army Medical Corps. Certain other forces must have completed a period of attachment in twelve months to a Regular unit of Cavalry, Artillery, Engineers, or Infantry, and have served and been trained for at least one year in the force to which they belong, before presenting themselves at the competitive examination in military subjects. The period of attachment to Regular units may be reduced if certain certificates are obtained. Candidates for commissions in the artillery must be able to pass an examination in the first year of service, with a certificate in riding and mathematics. They are not eligible for the Royal Engineers. (5) Conditions for Officers of the Colonial Military Forces are similar to those for the Special Reserve, &c., examinations. Officers' appointment to the Regular Force, Training, or Assistant Force, and the appointment of the Permanent Colonial Forces, is required. (6) Commissions are also given to Cadets of the Royal Military College, Kingston, Canada; the training of that establishment being similar to that at the Royal Military College. Candidates for commissions in the Royal Army Medical Corps and Army Veterinary Corps are not examined in military subjects, but must pass in the appropriate technical subjects; those for the Royal Engineers must pass examinations, one each in medicine and surgery; those for the Royal Artillery may pass a written examination in veterinary medicine, and one in mathematics. The examination is further required to the Royal Medical College for instruction in recruiting duties, hygiene, pathology, tropical medicine, military surgery and military administration.

Officers attend the School of Military Engineering at Chatham, where long and elaborate courses of instruction are given in all subjects appertaining to the work of the corps, including practical work in the field and in fortresses.

Regimental duties. Officers of the Royal Engineers are required to be proficient in the duties of a company, as financial accounts, stores, correspondence, the minor points of military law in their actual working, customs of the service, the management of regimental business, &c., with, in the case of the regimental officers, the rank and file of their corps. They are required to attend a number of courts-martial, as supernumerary members, before being permitted to attend one in the effective and official capacities of member or prosecutor, although they are able to handle the matters in their official departments and upon their rank and length of service. A course of musketry, theoretical and practical, is then gone through. Field training begins with lectures on the various evolutions of the squadron, after which the officers are instructed in the practice of musketry arranged by the commanders of squadrons, batteries or companies.

Before promotion from the rank of second-lieutenant to lieutenant, an examination must be passed in "Regimental Duties" (practical, oral, and written), which is attended with the assistance of the regiment, upon their rank and length of service. A course of musketry, theoretical and practical, is then gone through. Field training begins with lectures on the various evolutions of the squadron, after which the officers are instructed in the practice of musketry arranged by the commanders of squadrons, batteries or companies. The officer is then taken in hand by the commanding officer of his regiment, battalion or brigade. He is frequently examined in the subjects in which he has already been instructed, and is practically tested in physical training, tactics, law and organization. The next stage consists of regimental drills, which include every kind of practical work in the field which can be done by a unit under the command of a lieutenant-colonel. All officers have to pass examinations in military subjects for promotion until they attain the rank of major. The chief of these subjects are tactics, military topography, military engineering, military law, administration and military history. For majors, before promotion to lieutenant-colonel, an examination in "Tactical Fitness for Command" has to be passed. This examination is a test of ability in commanding the "three arms" in the field; a course of attachment to the two arms to which the officer does not belong being a necessary preliminary.

Arms Service Corps.—The officers of this corps have usually served for at least one year in the cavalry, infantry or Royal Marines, though commissions are also given to cadets of the Royal Military College, Kingston, Canada, and at the Royal Military College, Kingston, Canada, and at the Royal Military College, Kingston, Canada. The Royal Military College, Kingston, Canada, and at the Royal Military College, Kingston, Canada.

A thorough and detailed description of all kinds of forge, bastes, meat, groceries and other field supplies is given. The lectures and demonstrations in transport include the use of the latest types of war vehicles, mounted drill, wagon drill, carriages; embarking and disembarking of men and animals; entraining and detaining; harness and saddlery; transport by rail and sea, with the office work involved. This course of instruction is given at the Army Service Corps Training Establishment at Aldershot. A satisfactory examination having been passed, the officer is permanently taken into the corps. Before promotion to captain he has to go through a two months' course at the Staff College, &c., and is examined in the duties of a sub-department; interior economy of a company; military vehicles and pack animals; embarking, disembarking and duties on trains; and the supply of the military forces, before he is appointed to the office of captaining a sub-department; interior economy of a company; military vehicles and pack animals; embarking, disembarking and duties on trains; and the supply of the military forces, before he is appointed to the office of captain. During this period, their commissions are passed, and the officer is then eligible for promotion to captain. Before promotion to major, the officer is required to pass a course of instruction at the Royal Artillery Academy, before promotion to captain. During this period, their commissions are passed, and the officer is then eligible for promotion to captain. Before promotion to major, the officer is required to pass a course of instruction at the Royal Artillery Academy, before promotion to captain. During this period, their commissions are passed, and the officer is then eligible for promotion to captain. Before promotion to major, the officer is required to pass a course of instruction at the Royal Artillery Academy, before promotion to captain. During this period, their commissions are passed, and the officer is then eligible for promotion to captain. Before promotion to major, the officer is required to pass a course of instruction at the Royal Artillery Academy, before promotion to captain. During this period, their commissions are passed, and the officer is then eligible for promotion to captain. Before promotion to major, the officer is required to pass a course of instruction at the Royal Artillery Academy, before promotion to captain.
and oxen; remount depots; training of army horses; marching. (b) Diseases met with specially on active service. (c) Military etiquette and ethics; accounts and returns; administration and organization; veterinary hospitals, mobilization, map-reading and law. For the end of the corps he is trained in horse-riding to the satisfaction of the candidate; and before promotion to lieutenant-colonel, in law, duties of administrative veterinary officers at home and abroad, management of epizootics, sanitation of stables, horses-lines and transport.

**Army Pay Department.**—Officers are appointed to the department, on probation for a period not exceeding one year, after serving for five years in one of the other arms or branches of the service. At the end of this period the candidates are examined in the following subjects: composition of coins; the Reid, Weir, and Nuttall tables; ability to read and judge of the condition of coins, and make book; method of keeping accounts and preparing balance-sheets and monthly estimates; knowledge of pay-warrant, allowance regulations and financial instructions, book-keeping, by double entry and by a special sub-class attending the payment of soldiers; accounting, and quickness and neatness in work. On completion of five years' service, officers return to their regiments, unless they elect to remain with the department or are required by the Army Commissariat. There is a cavalry school at Netheravon.

**Mounted Infantry schools** have been established at Longmoor, Bulford and Korough, which train both officers and men in mounted infantry duties performed by civilized or semi-civilized tribes. Each officer must have at least two years' service, have completed a trained soldier's course of musketry and should have some knowledge of horsemanship and be able to ride. The instruction consists for the most part of riding school and field training. At Longmoor all officers receive five courses of instruction per annum; one "staff" course for Ordnance officers, lasting one month; two courses for senior officers of the Royal Artillery, lasting a fortnight each, and two courses for junior officers of the same branch, lasting a month each. For Royal Garrison Artillery officers there is one "staff" course lasting for seven months (this being a continuation of the previous "staff" course), and two courses, lasting four months each, for junior officers. There is also a school of gunnery to the infantry, which lasts for three weeks each, in siege artillery, are given each year.

The **Ordnance College** at Woolwich provides various courses of instruction in addition to those intended for officers of the Ordnance Department, such as land and sea, supply, transport, repairs, the maintenance of ordnance, in gunnery, guns, carriage, ammunition, electricity and chemistry; two courses for junior officers of the Royal Artillery in the same subjects; and a course for the Army Service Corps in mechanical drawing, which includes instruction for workmen, map-reading and electricity. It also gives courses of instruction to officers of the Royal Navy.

The **School of Military Engineering** at Chatham trains officers of the Corps on the same principles as those for the officers on the corps at which a limited number of officers of other corps may attend, provided they have passed through or been recommended for the Staff College. Other courses, in addition to the nine months' course for officers on probation for the corps are, one of twelve days for senior officers of the Corps in equipment and the latter (the former being a shorter course of instruction in the same subject for other officers; one for officers in other branches of the service in judging provisions; and one for lieutenant of the Royal Army Medical Corps in supply and transport.

Other colleges and schools are: the **Balloon School at Farnborough**, for officers of the Royal Engineers; **Schools of Electric Lighting** at Plymouth and Portsmouth; the **School of Signalling at Beeleigh**; for officers on probation of the **Royal Marine Artillery and **Gymnastics, also at Aldershot; and the **Army Veterinary School**, where a one month's course is given to officers of the mounted branches in the main principles of horsemastership, stable management and veterinary first aid, in addition to the one year's course for officers on probation for the Army Veterinary Corps. In the case of Russian, £80 is paid to the officer during his residence in Russia, in addition to the grant. Special arrangements are made with regard to the Chinese and Japanese languages; three being given by civilian instructors. Officers, who accept the two years' residence in those countries. Such residence officers receive £150 per annum, in addition to their pay, and a reward of £175 on passing the "Interpreters" examination. In the case of a few branches there are also courses for going through civilian courses of instruction; for example, at the London School of Economics and in the workshops of the principal railway companies. These courses enable the officer not only to familiarize himself with the language, but also to form an opinion as to his own knowledge, as compared with the knowledge of those outside his immediate surroundings.

**Promotion from the Ranks.**—In several armies aspirant officers may join as privates and pass through all grades. This is hardly the case in any British army. From the first that the young avanceur, as he is called in Germany, is a candidate for officer's rank, and he is treated accordingly as being living in the officers' mess and spending only a brief period in each branch. The system of promotion is one of the highest in the world. Enlisted men are either commissioned by the Corps or they may be transferred to the branches. In Germany the Germans have a certain system of training for officers. In Great Britain, largely owing to the chances of distinction afforded by frequent colonial expeditions, a fair number of non-commissioned officers receive promotion to combateants' commissions. The number is large, and the officers are selected from the following extracts from a return of 1909 (combatants only):

<table>

**Quartermasters and riding masters** are invariably promoted from the lower ranks.

Officers of reserve and second line forces are recruited in Great Britain both by direct appointment and by transfer from the regular forces. In universal service armies reserve officers are drawn from the regular army, and the reserve ranks being a continuation of the regular corps and are limited to that service. The majority of them are not liable for service in the army, and most of all from young men of good social standing who are gazetted after serving their compulsory period as privates in the ranks.

**Foreign Armies**

The training of the officer of a foreign army differs very slightly from that of the British officer. Each country specializes according to its own individual requirements, but in the main the training is much the same.

**Germany.**—The Germans attend more closely to detail—being even microscopical—and it has been said that a little grit in the German machine would not harm it. German staff officers have a reputation for having a great deal of initiative and to use that initiative, but he is expected to be discreet in the use of it and consequently undue insistence on literal obedience to instructions (as distinct from formal orders), and undue insistence on the part of the commander, is tried on the officer, but he is not in the least dangerous, for the regimental officer, if ignorant of the military situation, may, by acts of initiative, if necessary to maintain the discipline and harmony between the ranks, the general plan, seriously prejudice
The Germans attach special importance to instruction in the technical handling of artillery. 

Italy.—The Italians make a speciality of horsemanship, their cavalry officers studying for two years at the cavalry school at Modena, and for a further three years at the general staff school at Tor di Quinto. They also attach much importance to instruction in the handling of field artillery.

France.—The formal training of the French officer does not appear to differ essentially from that of the British officer; with this exception, there is no third term of four years to the non-commissioned ranks, a great feature of the educational system is the group of schools comprising the Saumur (cavalry), St. Maxent (infantry) and Versailles (artillery and engineers), which are intended for the sons of officers for commission and general staff appointments. Officers are commissioned from the "special school" of St. Cyr (cavalry and infantry) and the Ecole Polytechnique (artillery and engineers). 

United States.—The principal source from which the officers assigned to the army is the famous Military Academy at West Point, N.Y. The President may appoint forty cadets and generally chooses sons of army and navy officers. Each senator and each representative, and delegate in Congress may appoint on special request. Appointments are not made annually, but as vacancies occur through graduation of cadets, or their discharge before graduation. The maximum number of cadets under the Twelfth Census is 533. The commanding officer of the academy has the title of superintendent and commander. He is assisted by a board of adjutant-general, and he has the control of the general conduct of the corps of cadets, which is organized as a battalion, and is commanded by an officer detailed from the army, having the title of commandant of cadets. He has the temporary rank of lieutenant-colonel. An officer of the line, and the engineers and of ordnance are detailed to the general staff, to conduct practical military engineering and of ordnance and gunnery respectively. The heads of the departments of instruction have the title of professors. They are selected generally from officers of the army, and are appointed by the President, with the advice and consent of the Senate. The board of cadets and the professors constitute the academic board. The military staff and assistant instructors are officers of the army. The course of instruction covers four years and is very thorough. Theoretical instruction is supplemented by laboratory work, drawing, physics, astronomy, chemistry, ordnance and gunnery, art of war, civil and military engineering, law (international, constitutional and military), history and drill regulations of all arms. Practical instruction is given in military sciences, mathematics, gunnery, engineering, military history, artillery, surveying, reconnaissances, field engineering, construction of temporary bridges, simple astronomical observations, fencing, gymnastics and swimming. Cadets are a part of the army, and rank between second lieutenants and the highest grade of non-commissioned officers. The general pay is $80 per month, of which a part is of pay sufficient to cover all necessary expenses at the academy. About 30% of those entering are able to complete the course. The graduating class each year numbers, on an average, 60. A class is composed of cadets in their second, third, and fourth years. Members are assigned as second lieutenants to corps and arm, according to the recommendation of the academic board. A few at the head of the class go into the corps of engineers; the next in order generally go into the artillery; the third, the corps of ordnance, of which one is captain of company of cavalry and infantry. The choice of graduates as to arm of service and regiments is consulted as far as practicable. Any enlisted man who has served honestly and faithfully not less than two years, who is not more than twenty-one and thirty years of age, unmarried, a citizen of the United States and of good moral character, may aspire to a commission. To obtain it he must pass an educational and physical examination before a board of five officers. This board must also inquire into the character, capacity and record of the applicant. Most well-educated young men, unable to obtain appointments to West Point, enlist in the army for the purpose of obtaining a commission. Vacancies in the grade of second lieutenant remain, after the graduates of the Military Academy and qualified enlisted men have been utilized. The officers in the army must be eligible for appointment a candidate must be a citizen of the United States, unmarried, between the ages of twenty-one and twenty-seven years, and must be approved by an examining board of five officers, whose object shall be to determine the general ability, moral character and general fitness for the service. In time of peace very few appointments from civil life are made, but in time of war there is a large number.

Here, in addition to the Engineer School at Washington, D.C., four service schools for officers. These are: the Coast Artillery School at Fort Monroe, Virginia; the General Service and Staff College at Fort Leavenworth, Kansas; the Mounted Service School at Ft. Riley, Kansas; and the Chemical Warfare School at Washington, D.C. 

The commandants, staffs and instructors at these schools are officers specially selected. The garrison at Fort Monroe is composed of several companies of coast artillery. The lieutenants of these companies, who constitute the class, are relieved and replaced by others on 1st September of each year. The course of instruction comprises the following subjects: artillery, ballistics, engineering, steam and mechanics, electricity and mines, chemistry and explosives, military science, practical military exercises, photography, telegraphy and cording (the use of ropes, the making of various kinds of knots and lashing, rigging shears, &c., for the handling of heavy guns). July and August of each year are ordinarily devoted to artillery target practice. The course at the General Service and Staff College is for one year in each School. The class of student officers is made up of one lieutenant from each regiment of infantry and cavalry and others as may be detailed. They are assigned to the formations comprising the garrison, normally a regiment of infantry, a squadron (four troops) of cavalry and a battery of field artillery. The departments of instruction are: military art, tactics, organization, gunnery, engineering, and general military science is paid to practical work in the minor operations of war, the troops of the garrison being utilized in connexion therewith. At the close of the final examinations of each class at Fort Monroe and Fort Riley, the students are detailed for the following services: Engineers and scientists are reported to the assistant-general of the army. Two from each class of the Artillery School, and not more than five from each class at the General Service and Staff College, are thereafter, so long as they remain in the service, recommended for promotion to the assistant-generals. The work of the Mounted Service School at Fort Riley is mainly practical, and is carried on by the regular garrison, which usually, in time of peace, consists of two squadrons of cavalry and three field batteries. The government reservation at Fort Riley comprises about 400,000 of varied terrain, so that opportunities are afforded, and taken advantage of, for all kinds of field operations.

The Army Medical School is established at Washington. The faculty consists of four or more instructors selected from the senior officers of the various branches of the medical department. The period of residence is of five months, beginning annually in November. The student officers are recently appointed medical officers, and such other medical officers, available for detail, as may desire to take the course. Instructors are appointed by the Surgeon General of the army, are given to the following subjects: duties of medical officers in peace and war; hospital administration; military medicine, surgery and hygiene; microscopy and bacteriology; hospital corps drill and first aid to the wounded. By order of Secretary of War, military cadets are no longer admitted to the academy, but are graduated in the military schools.

OFFICIAL (Late Lat. officialis, for class, Lat. apparitor, from officium, office, duty), in general any holder of office under the state or a public body. In ecclesiastical law the word "official" has a special technical sense as applied to the official exercising a diocesan bishop's jurisdiction as his representative and in his name (see ECCLESIASTICAL JURISDICTION). The title of "official principal," together with that of "vicar-general," is in England now merged in that of "chancellor" of a diocese (see CHANCELLOR).

OFFICIAL, a term applied in medicine to drugs, plants and herbs, which are sold in chemists' and druggists' shops, and to medical preparations of such drugs, &c., as are made in accordance with the prescriptions authorized by the pharmacopoeia. In the latter sense, modern usage tends to supersede "officinal" by "official." The classical Lat. officina meant a workshop, manufactory, laboratory, and in medieval monastic Latin was applied to a general store-room (see Du Cange, Gloss., s.v.); it thus became applied to a shop where goods were sold rather than a workshop, whence it was transferred to a diocesan bishop.

OGDEN, a city and the county-seat of Weber county, Utah, U.S.A., at the confluence of the Ogden and Weber rivers, and about 35 m. S. of Salt Lake City. Pop. (1890) 14,880; (1900) 16,313, of whom 3502 were foreign-born; (1910) 25,505. It is served by the Union Pacific, the Southern Pacific, the Oregon Short Line, and the Denver & Rio Grande railways. It is situated at an elevation of about 4300 ft. in the picturesque region of the Wasatch Range, Ogden Cañon and the Great Salt Lake. Ogden is an agricultural and fruit-growing region, and gold and silver are mined in the vicinity. It has various manufactures, and the value of the factory product increased from $1,242,214 in 1900 to $3,997,057 in 1905, or 141.3%. Ogden, which is said to have been named in honour of John Ogden, a trapper, was laid out under the direction of Brigham Young in 1850, and was incorporated in the next year; in 1856 it received a new charter, but since 1898 it has been governed under a general law of the state.

ODENSBURG, a city and port of entry of St. Lawrence county, New York, U.S.A., on the St. Lawrence river, at the mouth of the river Chittenango, 27 m. N. E. of Syracuse, New York. Pop. (1890) 11,662; (1900) 12,633, of whom 3222 were foreign-born; (1910) 15,933. It is served by the New York Central & Hudson River and the Rutland railways, and by several lake and river steamboat lines connecting with ports on the Great Lakes, the city being at the head of lake navigation.
on the St Lawrence. Steam ferries connect Ogdensburg with Prescott, Ontario. The city is the seat of the St Lawrence State Hospital for the Insane (1890), and has a United States Customs House and a state armory. The city became the see of a Roman Catholic bishop in 1872, and here Edgar Philip Wadhams (1817-1891) laboured as bishop in 1872-1891. It is the port of entry of the Oswegatchie customs district, and has an extensive commerce, particularly in lumber and grain. The city has various manufactures, including lumber, flour, wooden-ware, brass-ware, silks, woollens and clothing. The value of the factory products increased from $2,260,889 in 1900 to $3,057,271 in 1905, or 35.2%.

The site of Ogdensburg was occupied in 1749 by the Indian settlement of La Presentation, founded by the Abbé François Piquet (1705-1781) for the Christian converts of the Iroquois. At the outbreak of the War of Independence the British built here Fort Presentation, which they held until 1796, when, in accordance with the terms of the Jay Treaty, the garrison was withdrawn. Abraham Ogden (1743-1798), a prominent New Jersey lawyer, bought land here, and the settlement which grew up around the fort was named Ogdensburg.

During the early part of the War of 1812 it was an important post on the American line of defence. On the 4th of October 1812 Colonel Letchbridge, with about 750 men, prepared to attack Ogdensburg but was driven off by American troops under General Jacob Brown. On the 22nd of February 1813 both fort and village were captured and partially destroyed by the British. During the Canadian rising of 1837-1838 Ogdensburg became a rendezvous of the insurgents. Ogdensburg was incorporated as a village in 1818, and was chartered as a city in 1868.

Ogee (probably an English corruption of Fr. ogive, a diagonal groin rib, being a moulding commonly employed; equivalents in other languages are Lat. cyma-reversa, Ital. gola, Fr. cymaïse, Ger. Kehlbleise), a term given in architecture to a moulding of a double curvature, convex and concave, in which the former is the uppermost (see MOULDING). The name "ogee-arch" is often applied to an arch formed by the meeting of two contrasted ogees (see ACH).

Ogier the Dane, a hero of romance, who is identified with the Frankish warrior Autchar (Autgarius, Autarius, Otgarius, Ogier). Ogier was the son of the Danish King Harald, accompanied Gerberga, widow of Carломon, Charlemagne's brother, and her children to the court of Desiderius, king of the Lombards, with whom he marched against Rome. In 773 he submitted to Charles at Verona. He then entered the close of St Faro at Meaux, and Mabillon (Acta SS. ord. St Benedicti, Paris, 1677) has left a description of his monument there, which had figures of Ogier and his friend Benedict or Benoit, with smaller images of Roland and la belle Aude and other Carolingian personages.

In the chronicle of the Pseudo Turpin it is stated that innumerable cantilenae were current on the subject of Ogier, and his deeds were probably sung in German as well as in French. The Ogier of romance may be definitely associated with the flight of Gerberga and her children to Lombardy, but it is not safe to assume that the other scattered references all relate to the same individual. Colour is lent to the theory of his Bavarian origin by the fact that he, with Duke Naimes of Bavaria, led the Bavarian contingent to battle at Roncesvaux.

In the romances of the Carolingian cycle he has, on account of his revolt against Charlemagne, placed in the family of Doon de Mayence, being the son of Gautier de "Dannemarche." The Enfances Ogier of Adénès le Rois, and the Chevalerie Ogier de Dannemarche of Raimbert de Paris, are doubtless based on earlier chansons. The Chevalerie is divided into twelve songs or branches. Ogier, who was the hostage for his father at Charlemagne's court, fell into disgrace, but regained the emperor's favour by his exploits in Italy. One Easter at the court of Laon, however, his son Balduinet was slain by Charlemagne's son, Charlot, with a chess-board (cf. the incident of Renaud and Bertholais in the Quatre Fils Aymon). Ogier in his rage slays the queen's nephew Loher, and would have slain Charlemagne himself but for the intervention of the knights, who connived at his flight to Lombardy. In his stronghold of Castelforte he resisted the imperial forces for seven years, but was at last captured by Turpin, who incarcerated him at Reims, while his horse Broiefort, the sharer of his exploits, was made to draw stones at Meaux. He was eventually released to fight the Saracen chief Bréhus or Brahiher, whose armies had ravaged France, and who had defied Charlemagne to single combat. Ogier only consented to fight after the surrender of Charlot, but the prince was saved from his barbarous vengeance by the intervention of St Michael. The giant Bréhus, despite his 17 ft. of stature, was overthrown, and Ogier, after marrying an English princess, the daughter of Angart (or Edgard), king of England, received from Charlemagne the fiefs of Hainaut and Brabant.

A later romance in Alexandrine (Brit. Mus. MS. Royal 15 E v.) contains marvels added from Celtic romance. Six fairies visit his cradle, the sixth, Morgan la Fay, promising that he shall be her lover. He has a conqueror's career in the East, and after two hundred years in the "castle" of Avalon returns to France in the days of King Philip, bearing a firebrand on which his life depends. This is destroyed when Philip's widow queen forebodes her death to carry him, 1842, Morgan la Fay. The prose romance printed at Paris in 1498 is a version of this later poem.

The fairy element is prominent in the Italian legend of Uggieri il Danese, the most famous redaction being the proseLibro delle bataglie del Danese (Milan, 1498), and in the English Famous and renowned history of Morivine (see OGER: the Dane, translated by J. M. (London, 1612). The Spanish Urgel was the hero of Lope de Vega's play, the Marques de Mantua. Ogier occupies the third branch of the Scandinavian Karlamagnus saga; his fight with Brunambon (Enfances Ogier) was the subject of a Danish folk-song; and as Holger Danske he became a Danish national hero, who fought against the German Dietrich of Bern (Theodic "of Verona"), and was invested with the common tradition of the king who sleeps in a mountain ready to awaken at need. Whether he had originally anything to do with Denmark seems doubtful. The surname le Danois has been explained as a corruption of "Ardennois and Dannemarche as the marches of the Ardenne."

Ogilby, John (1600-1679), British writer, was born in or near Edinburgh in November 1600. His father was a prisoner within the rules of King's Bench, but by speculation the son found money to apprentice himself to a dancing master and to obtain his father's release. He accompanied Thomas Wentworth, earl of Strafford, when he went to Ireland as lord deputy, and became tutor to his children. Strafford made him deputy-master of the revels, and he built a little theatre in St Werburgh Street, Dublin, which was very successful. The outbreak of the Civil War ruined his fortunes, and in 1646 he returned to England. Finding his way to Cambridge, he learned Latin from kindly scholars who had been impressed by his industry. He then went to Italy, where he translated into English Horace's Odes, which brought him a considerable sum of money. The success of this attempt encouraged Ogilby to learn Greek from David Whitefriars, who was usher in the school kept by James Shirley the dramatist. Homer his liads translated ... appeared in 1660, and in 1665 Homer his Odysseys translated ... Anthony à Wood asserts that in these undertakings he had the assistance of Shirley. At the Restoration Ogilby received a commission for the "poetical part" of the coronation. His property was destroyed in the Great Fire of 1666, but he rebuilt his house in Whitefriars, and set up a printing press, from which he issued...
many magnificent books, the most important of which were a series of atlases, with engravings and maps by Hollar and others. He styled himself "His Majesty's Cosmographer and Geographical Printer." He died in London on the 4th of September 1676.

Ogilby also translated the fables of Aesop, and wrote three epic poems. His bulky output was ridiculed by John Dryden in Maccabaeus and by Alexander Pope in The Dunciad.

Ogilvy (or Ogilvy), JOHN (c. 1580–1615), English Jesuit, was born in Scotland and educated mainly in Germany, where he entered the Society of Jesus, being ordained priest at Paris in 1613. As an emissary of the society he returned to Scotland in this disguise as a soldier, and in October 1614 he was arrested in Glasgow. He defended himself stoutly when he was tried in Edinburgh, but he was condemned to death and was hanged on the 28th of February 1615.

A True Relation of the Proceedings against John Ogilvy, a Jesuit (Edinburgh, 1615), but left two sons. The elder of these, Sir John Ogilvy (d. 1484), was the father of Sir James Ogilvy (1470–1504), who was made a lord of parliament in 1491, and the younger, Sir Walter Ogilvy, was the ancestor of the earls of Finglater.

The earldom of Finglater, bestowed on James Ogilvy, Lord Ogilvy of Deskford, in 1658, was united in 1711 with the earldom of Seafield and became dormant after the death of James Ogilvy, the 7th earl, in October 1811 (see Seafield, Earls of).

Sir James Ogilvy's descendant, James Ogilvie, 5th Lord Ogilvy of Airlie (c. 1541–1606), a son of James Ogilvy, master of Ogilvy, was killed at the battle of Pinkie in 1567, took a leading part in Scottish politics during the reigns of Mary and James VI. His grandson, James Ogilvy (c. 1593–1666), was created earl of Airlie by Charles I., at York in 1639. A royal partisan of the king, he joined Montrose in Scotland in 1644 and was one of the royalist leaders at the battle of Kilsyth. The destruction of the earl's castles of Airlie and of Forther in 1649 by the earl of Argyll, who "left him not in all his lands a cock to crow day," gave rise to the song "The bonny house o'Airlie." His eldest son, James, the 2nd earl (c. 1615–1704) also fought among the Covenanters, and was taken prisoner, but he was released in the following year as a consequence of Montrose's victory at Kilsyth. He was again a prisoner after the battle of Philiphaugh and was sentenced to death in 1646, but he escaped from his captivity at St Andrews and was afterwards pardoned. Serving with the Scots against Cromwell he became a prisoner for the third time in 1651, and was in the Tower of London during most of the years of the Commonwealth. He was a fairly prominent man under Charles II. and James II., and in 1668 he ranged himself on the side of William of Orange. This earl's grandson, James Ogilvy (d. 1731), took part in the Jacobite rising of 1715 and was attainted; consequently on his father's death in 1717 he was not allowed to succeed to the earldom, although he was pardoned in 1725. When he died his brother John (d. 1761) became earl de jure, and John's son David (1725–1803) joined the standard of Prince Charles Edward in 1745. He was attainted, and after the defeat of the prince at Culloden escaped to Norway and Sweden, afterwards serving in the French army, where he commanded "le regiment Ogilvy" and was known as "le bel Ecosais." In 1778 he was pardoned and was allowed to return to Scotland, and his family became extinct when his son David died unmarried in April 1822. After this event David's cousin, another David Ogilvy (1785–1849), claimed the earldom. He asserted that he was not attainted by the two attainers, but the House of Lords decided that these barred his succession; however, in 1826 the attainers were reversed by act of parliament and David became 6th earl of Airlie. He died on the 20th of August 1849 and was succeeded by his son, David Graham Drummond Ogilvy (1826–1882), who was a Scottish representative peer for over thirty years. The latter's son, David Stanley William Drummond Ogilvy, the 8th earl (1856–1890), served in Egypt in 1865 and 1885, and was killed on the 11th of June 1900 during the Boxer War while at the head of his regiment, the 12th Lancers. His titles then passed to his son, David Lyulph Gore Wobsey Ogilvy, the 9th earl (b. 1893).

A word may be said about other noteworthy members of the Ogilvy family. John Ogilvy, called Powrie Ogilvy, was a political adventurer who professed to serve King James VI. as a spy and who certainly served William Cecil in this capacity. Mariona Ogilvy (d. 1575) was the mistress of Cardinal Beaton. Sir George Ogilvy (d. 1603), a supporter of Charles I. during the struggle with the Covenanters, was created a peer as lord of Banff in 1642; this dignity became dormant, or extinct, on the death of his descendant, William Ogilvy, the 8th lord, in June 1803. Sir George Ogilvy of Barras (d. c. 1679) defended Dunnottar Castle against Cromwell in 1651 and 1652, and was instrumental in preventing the regalia of Scotland from falling into his hands; in 1660 he was created a baronet, the title becoming extinct in 1837.

See Sir R. Douglas, Peerage of Scotland, new ed. by Sir J. B. Paul (1904 fo.).

Ogive (a French term, of which the origin is obscure: auge, trough, from Lat. augere, to increase, and an Arabic astrological word for the "highest point," have been suggested as derivations), a term applied in architecture to the diagonal ribs of a vault. In France the name is generally given to the pointed arch, which has resulted in its acceptance as a title for Gothic architecture, there often called "le style ogival."

Oglethorpe, James Edward (1667–1758), English general and philanthropist, the founder of the state of Georgia, was born in London on the 21st of December 1696, the son of Sir Theophilus Oglethorpe (1650–1702) of Westbrook Place, Godalming, Surrey. He entered Corpus Christi College, Oxford, in 1714, but in the same year joined the army of Prince Eugène. Through the recommendation of the duke of Marlborough he became aide-de-camp to the prince, and he served with distinction in the campaign against the Turks, 1716–17, more especially at the siege and capture of Belgrade. After his return to England he was in 1722 chosen member of parliament for Haslemere. He devoted much attention to the improvement of the circumstances of poor debtors in London prisons; and for the purpose of providing an asylum for persons who had become insolvent, and for oppressed Protestants on the continent, he projected the settlement of a colony in America between Carolina and Florida (see Georgia). In 1745 Oglethorpe was promoted to the rank of major-general. His conduct in connexion with the Scottish rebellion of that year was the subject of inquiry by court-martial, but he was acquitted. In 1755 he was raised to the rank of general. He died at Cranham Hall, Essex, on the 1st of July 1785.

Sir Theophilus Oglethorpe, the father, had four sons and four daughters, James Edward being the youngest son, and another James (b. 1688) having died in infancy. Of the daughters, Anne Henrietta (b. 1680–1685), Eleanor (b. 1684) and Frances Charlotte (b. 1680), the two elder were "Fatigued at Sea," having played rather curious parts in the Jacobitism of the time; their careers are described in the essay on "Queen Oglethorpe" by Miss A. Shield and A. Lang, in the latter's Historical Mysteries (1904).

Ogowé, one of the largest of the African rivers of the second class, rising in 3° S. in the highlands known as the Crystal Range, and flowing N.W. and W. to the Atlantic, a little south of the equator, and some 400 m. following the coast, north of the mouth of the Congo. Its course, estimated at 750 m., lies wholly within the colony of Gabun, French Congo. In spite of its considerable size, the river is of comparatively little use for navigation, as
OGRE—OHIO
25

rapids constantly occur as it descends the successive steps of the interior tablelands. The principal obstructions are the falls of Duque, in 43° 3' E.; Bunji, in 42° 3' 35"; Changwe, in 42° 16'; Bouc, in 42° 53'; and the rapids formed in the passes by which it breaks through the outer chains of the mountainous zone, between 104° and 112° E. In its lower course the river passes through a lacustrine region in which it sends off secondary channels. These channels, before uniting with the main stream, traverse a series of lakes, one north, the other south, of the river. These lakes are natural regulators of the river when in flood. The Ogówé has a large number of tributaries, especially in its upper course, but of these few are navigable. The most important are the Lolo, which joins on the south bank in 10° 20' E., and the Ivindo, which enters the Ogówé a few miles lower down. Below the Ivindo the largest tributaries are the Ofowé, 400 yds. wide at its mouth (11° 47' E.), but unnavigable except in the rains, and the Nguye, the largest southern tributary, navigable for 60 m. to the Samba or Eugénie Falls. Apart from the narrow coast plain the whole region of the lower Ogówé is densely forested. It is fairly thickly populated by Bantu tribes who have migrated from the interior. The fauna includes the gorilla and chimpanzee.

The Ogówé rises in March and April, and again in October and November; it is navigable for steamers in its low-water condition as far as the junction of the Nguye. At flood time the river can be ascended by steamers for a distance of 235 m., a place called N'Jole. The first person to explore the valley of the Ogówé was Paul du Chaillu, who travelled in the country during 1857-1859. The extent of the delta and the immense volume of water carried by the river gave rise to the belief that it must either be a bifurcation of the Congo or one of the leading rivers of Africa. However, in 1882 Savorogna de Brizza (the founder of French Congo) reached the sources of the river in a rugged, sandy and almost treeless plateau, which forms the watershed between its basin and that of the Congo, whose main stream is only 140 m. distant. Since that time the basin of the Ogówé has been fully explored by French travellers.

OGRE, the name in fairy tales and folk-lore of a malignant monstrous giant who lives on human flesh. The word is French, and occurs first in Charles Perrault's *Histoires ou contes du temps passé* (1697). The first English use is in the translation of a French version of the *Arabian Nights* in 1713, where it is spelled hogre. Attempts have been made to connect the word with Ugeri, the name of the Magyars or Hungarians, but it is generally accepted that it was adapted into French from the O. Span. *huero, kuro, uero*, cognate with It. orco, i.e. Orcus, the Latin god of the dead and the infernal regions (see Pluto), who in Romance folk-lore became a man-eating demon of the woods.

OGYES, or Ogygus, in Greek mythology, the first king of Thebes. During his reign a great flood, called the Ogygian deluge, was said to have overwhelmed the land. Similar legends were current in Attica and Phrygia. Ogysse is variously described as a Boeotian autochthon, as the son of Cadmus, or of Poseidon.

O'HAGAN, THOMAS O'HAGAN, 1st Baron (1812-1885), lord chancellor of Ireland, was born at Belfast, on the 29th of May 1812. He was educated at Belfast Academical Institution, and was called to the Irish bar in 1836. In 1840 he removed to Dublin, where he appeared for the repeal party in many political trials. His advocacy of a continuance of the union with England, and his appointment as solicitor-general for Ireland in 1861 and attorney-general in the following year, lost him the support of the Nationalist party, but he was returned to parliament as member for Tralee in 1863. In 1865 he was appointed a judge of common pleas, and in 1868 became lord chancellor of Ireland in Gladstone's first ministry. He was the first Roman Catholic to hold the office of chancellor since the reign of James II., an act throwing open the office to Roman Catholics having been passed in 1867. In 1870 he was raised to the peerage, and held office until the resignation of the ministry in 1874. In 1880 he again became lord chancellor on Gladstone's return to office, but resigned in 1881. He died in London on the 1st of February 1885, and was succeeded by his eldest son, Thomas Towneley (1876-1900), and by another son, Maurice Herbert Towneley (b. 1882).

O'HIGGINS, Bernardo (1785-1842), one of the foremost leaders in the Chilean struggle for independence and head of the first permanent national government, was a natural son of the Irishman Ambrosio O'Higgins, governor of Chile (1788-1796), and was born at Chillán on the 20th of August 1787. He was educated in England, and after a visit to Spain he lived quietly on his estate in Chile till the revolution broke out. Joining the nationalist party led by Martinez de Rozas, he distinguished himself in the early fighting against the royalist troops despatched from Peru, and was appointed in November 1813 to supersede J. M. Carrera in command of the patriot forces. The rivalry that ensued, in spite of O'Higgins's generous offer to serve under Carrera, eventually resulted in O'Higgins being isolated and overwhelmed with the bulk of the Chilean forces at Rancagua in 1814. O'Higgins with most of the patriots fled across the Andes to Mendoza, where José de San Martín (q.v.) was preparing a force for the liberation of Chile. San Martín espoused O'Higgins's part against Carrera, and O'Higgins, recognizing the superior ability and experience of San Martín, readily consented to serve as his subordinate. The loyalty and energy with which he acted under San Martín contributed not a little to the organization of the liberating army, to its transportation over the Andes, and to the defeat of the royalists at Chacabuco (1817) and Maipo (1818). After the battle of Chacabuco O'Higgins was entrusted with the administration of Chile, and he ruled the country firmly and well, maintaining the close connexion with the Argentine, co-operating loyally with San Martín in the preparation of the force for the invasion of Peru, and seeking, as far as the confusion and embarrassments of the time allowed, to improve the welfare of the people. After the overthrow of the Spanish supremacy in Peru had freed the Chilians from fear of attack, an agitation set in for constitutional government. O'Higgins at first tried to maintain his position by calling a congress and obtaining a constitution which invested him with dictatorial powers. But popular discontent grew in force; risings took place in Concepcion and Coquimbo, and on the 28th of January 1823 O'Higgins was finally.patriotic enough to resign his post of director-general, without attempting to retain it by force. He retired to Peru, where he was granted an estate and lived quietly till his death on the 24th of October 1842.

O'HIGGINS, Bernardo. *Vida de O'Higgins* (Santiago, 1882), and M. L. Armumátégui, *La Dictadura de O'Higgins* (Santiago, 1853); both containing good accounts of O'Higgins's career. Also P. B. Figueroa, *Diccionario biográfico de Chile*, 1550-1887 (Santiago, 1901), and C. D. N. Tubi, *Razgos biográficos de nombres notables de Chile* (Valparaiso, 1886).

OHIO, a north central state of the United States of America, lying between latitudes 38° 27' and 41° 57' N. and between longitudes 86° 34' and 84° 49' W. It is bounded N. by Michigan and Lake Erie, E. by Pennsylvania and the Ohio river which separates it from West Virginia, S. by the Ohio river which separates it from West Virginia and Kentucky, and W. by Indiana. The total area is 41,490 sq. m., 300 sq. m. being water surface.

Physiography.—The state lies on the borderland between the Prairie Plains and the Alleghany Plateau. The disturbances among the underlying rocks of Ohio have been slight, and originally the surface was a plain only slightly undulating: stream dissection changed the region to one of numberless hills and valleys; glacial drift then filled up the valleys over large broken areas, forming the remarkably level till plains of northern Ohio; but at the same time other areas were broken by the uneven distribution of the drift, and south-eastern Ohio, which was unglaciated, retains its rugged hilly character, gradually merging with the typical plateau country farther S.E. The average elevation of the state above the sea is about 860 ft., but extremes vary from 425 ft. at the confluence of the Great Miami and Ohio rivers in the S.W. corner to 1540 ft. on the summit of Hugus Hill about 18I m. E. of Bellefontaine in the west central part.
The main water-parting is formed by a range of hills which are composed chiefly of drift and extend W.S.W. across the state from Trumbull county in the N.E. to Darke county, or about the middle of the W. border. North of this water-parting the rivers flow into Lake Erie. In Ohio, it is composed of sandstone and limestone. Nearly all of the remaining part of the state have a rapid current. Those that flow directly into the lake are short, but some of the rivers of this region, such as the Cuyahoga and the Grand, are turned by drift ridges into sinuous courses and flow through narrow valleys with numerous falls or cascades. A tributary of the Muskingum river, the Tuscarawas, descends more than 200 ft. in 3 m.; a part of its course is between walls of sandstone 100 ft. or more in height, and near its mouth, at Cleveland, its bed has been cut through 60 ft. of drift in a single season. The Ohio river and its tributaries have their sources in swamps on the water-parting and flow directly to the lake through narrow valleys. The till plains of north-western Ohio are drained chiefly by the Maumee and Sandusky. Maumee is only 1 ft. per mile, while that of the Sandusky decreases from about 7 ft. per mile at Upper Sandusky to 2 5 ft. per mile below Fremont. South of the water-parting the average length of the rivers is greater than that of those N. of it, and their average fall is much less. In the S.W. the Great Miami and Little Miami rivers have uniform falls through basins that are distinctly rolling and that contain the extremes of elevation for the entire state. The central and S. middle part of the state is drained by the Ohio river, its tributaries, and the Muskingum and its tributaries. The drift of this region formed mostly in Devonian shale, and is bounded on the W. by a limestone rim and on the E. by precipitous valleys filled with glacial drift. In its middle portion the basin is about 40 m. wide and only moderately rolling, but toward the coast the basin is obliterated and the surface is composed of high hills. In the E. part of Ohio the Muskingum river and its tributaries drain an area of about 7500 sq. m. or nearly one-fifth of the entire state. Much of the unglacial or driftless portion of the state, including all of the S.W. counties, has a surface that has a gentle or even sluggish flow, they have greatly broken the surface of the country. The upper portion of the basin is about 100 m. in width, but it becomes quite narrow below Zanesville. The Ohio river, flowing through the center of the state, and Lake Erie forms the N. boundary for a distance of 230 m. At the W. end of the lake are Sandusky and Maumee bays, each with a good natural harbor. In this vicinity also are various smaller indentations of the lake, formed between 1913 and 1915, which are now used as lakes by resorters. On Put-in-Bay Island are some interesting "hydration" caves, i.e. caves formed by the uplifting and forming of the rocks by the evaporation of water in the cave. In the central and E. part of the state, illusion and sunfish are caught in the rivers and streams.

Fauna.—Bears, wolves, bisons, deer, wild turkeys, and wild pigeons are common in Ohio, but they long ago disappeared. Foxes are still found in considerable numbers in suitable habitats: opossums, skunks and raccoons are plentiful in some parts of the state; and rabbits and squirrels are still numerous. All of these wild animals furnish food for the numerous wild fowls, which are abundant and plentiful. Whitefish, bass, trout and pickerel are an important food supply obtained from the waters of the lake, and some perch, catfish and sunfish are caught in the rivers and streams.

Ohio.—The state was 184 in. 1 ft. greater in the S. and E. and least in the N.W. At Marietta, for example, it is 42 1 in., but at Toledo it is only 30 8 in. Nearly 60% of it comes in the spring and summer. The average annual fall of snow is about 37 in. in the N. and 22 in. in the S. The prevailing winds in most parts are westerly, but sudden changes, as well as the extremes of temperature, are caused mainly by the frequent shifting of the wind from N.W. to S.W. and from S.W. to N.W. at Cleveland and Cincinnati the winds blow mostly from the S.E.

Soil.—In the driftless area, the S.E. part of the state, the soil is largely a decomposed result of the underlying rocks, and its fertility varies according to their composition; there is considerable limestone in the E. central portion, and this renders the soil very productive. In the valleys also are strips covered with a fertile alluvial deposit. In the other parts of the state the soil is composed mainly of loam, clay, and gravel, and is more fertile, however, in the basins of the Great Miami and Little Miami rivers, where there is a mixture of decomposed limestone and where extensive areas with a clay subsoil are covered with drift. It is well cultivated and its crops are improved and increased. There were altogether 276,719 farms; of these, 93,028 contained less than 50 acres, 182,802 contained less than 100 acres, 156,106 contained less than 175 acres, 26,659 contained 175 acres or more, and 407 contained 100 acres or more. The average size of the farms decreased from 120 5 acres in 1850 to 92 9 acres in 1880 and 80 4 acres in 1900. Nearly seven-tenths of the farms were worked in 1900 by owners or owners' tenants, 24,051 were worked by cash tenants, 27,000 by hired laborers, and 97,000 by negroes as owners, tenants or managers. There is a great variety of produce, but the principal crops are Indian corn, wheat, oats, hay, potatoes, apples and tobacco. In 1900 the acreage of cereals constituted 69 4% of the acreage of crops, and the acreage of corn, wheat, oats and rye accounted for 50 7 of the total acreage of all crops, or 46 1 of the acreage of cereals. The acreage of corn was 67,301,144 bushels in 1870; 152,055,360 bushels in 1890 and 152,056,125 bushels in 1900, when it was grown in 8,375,000 acres and the state ranked seventh among the states in its production. The acreage of wheat was 27,882,159 bushels in 1870; 50,376,800 bushels (grown on 3,209,014 acres) in 1890; and 23,532,500 bushels (grown on 1,480,000 acres) in 1900. The acreage of oats was 52,347,349 bushels in 1870; 80,411,000 bushels (grown on 52,562,500 acres) in 1890; and 56,225,000 bushels (grown on 1,730,000 acres) in 1900. The total acreage of hay was 1,358,947 in 1850; 2,117,925 in 1900; and 1,925,000 in 1910. In 1900 the acreage of tobacco was 581,000 acres, and 1,715,221 bushels in 1870 to 1,053,240 bushels in 1890 and 829,000 bushels in 1900. The number of swine was 1,120,090 in 1870; 447,000 in 1890; and 420,000 in 1900. The number of cattle was 1,358,947 in 1850; 2,117,925 in 1900; and 1,925,000 in 1910. In 1900 there were 866,832 and in 1910 907,400 milk cows in the state. The number of sheep decreased from 7,000 in 1870 to 2,500 in 1910. In 1910 there were 3,023,500 sheep in the state. The number of horses was 463,397 in 1850; 1,068,170 in 1900; and 977,000 in 1910. The cultivation of tobacco was of little importance in the state until about 1840; but the product increased from 10,445,449 lb. in 1870 to 12,734,400 lb. in 1890, and to 15,596,000 lb. in 1900. In 1900 the crop was grown on 71,422 acres; in 1900 the crop was grown 83,300 lb. grown on 90,000 acres. The value of all farm products in 1890 was $257,065,826. Indian corn, wheat and oats are grown in all parts, but the eastern counties produce the largest amount. In 1890 corn and two-thirds of the wheat, and in the N. half, especially in the N.E. corner, are the best oat-producing counties. The N.E. quarter ranks highest in the production of hay. Domestic animals are grown in all parts of the state, but the greatest number is in the S.W. part. The total value of all products was $317,027. Propagation facilities are being greatly improved, and there are stringent laws for the protection ofimmel fish. Inland streams and lakes are well supplied with game fish; state laws prohibit the sale of game fish and their being taken, except with licenses for hunting.

Mineral Products.—The mineral wealth of Ohio consists largely of bituminous coal and petroleum, but the state also ranks high in the production of natural sandstone, limestone, granite, sandstone, lime and sand. The state consists mostly of sandstone, but it is also the second state in the amount of sandstone production, and it is the second state in the amount of sandstone produced. The state produced 3,724,419 short tons in 1900, and 26,270,639 short tons in 1910, or 31,324,219 short tons. There are 29 counties in which coal is produced, but 81% of it in 1908 came from Belmont, Athens, Jefferson, Guernsey, Perry, Holmes, Tuscarawas and Jackson counties. Two of the most productive petroleum fields of the United States are in part in Ohio; the Appalachian field in the E. and S. parts of the state, and the Lima-Indiana field in the N.W. part. Some petroleum was obtained in the S.E. as early as 1899, but the state's output was comparatively small until after petroleum.
was discovered in the N.W. in 1884; in 1883 the output was only 47,632 barrels, four years later it was 5,022,632 barrels, and in 1896 it was 23,041,169 barrels, or 39% of the total output in the United States. For the next two years, however, there was a decrease, and in 1896 the output had fallen to 10,887,727 barrels of 6,748,676 barrels (valued at $6,861,885) was obtained in the Lima district, 4,109,035 barrels (valued at $7,315,667) from the southeast district, and 186 barrels (valued at $80) suitable for lubricating purposes, from the Mecca-Belden district in Trumbull County. Lorain County, which was worth $1,350,000. N. The output in the central and north-western parts of the state. That in the E. was first used in 1866, the N.W. field was opened in 1884, and the central field was opened in 1887. The value of the state's yearly oil flow increased steadily from 1884 to 1897, and from $1,683,935 in 1893, and then increased to $8,244,835 in 1908. Some of the best sandstone in the United States is obtained from Cuyahoga and Lorain counties; it is exceptionally pure, with about 85% being pure silica. Durable and varied in colour light grey, bluish grey or grey. From the Ohio sandstone known as Berea grit a very large portion of the country's gristmills and pulpstones has been obtained; in 1908 the value of Ohio's output of these stones was $842,126. Some of the Berea grit is suitable for making olistolites and scythe stones. Although the state has a great amount of limestone, especially in Erie and Ottawa counties, its dull colour renders it unsuitable for most building purposes. In 1908, the output of stone was 462,539,450 tons and for making quick lime. The quantity of Portland cement made in Ohio in 1896 was valued at 57,000 barrels in 1890 at $50,113 barrels in 1902 and at 1,521,704 barrels in 1908. Beds of rock gypsum, which is the chief source of Ohio's output of gypsum, are present. There is some iron ore in the eastern and south-eastern parts of the state, and the mining of it was begun early in the 19th century; but the output decreased from 254,294 tons in 1880 to only 25,554 tons (all carbonate) in 1908. In Ohio, in 1908, 3,472,635 tons of the mineral were produced. Iron ore, and the steel industry, is an iron and steel. This industry was established near Youngstown in 1858. The output of the state increased from 3,770,828 tons in 1880 to $18,395,756 in 1900 and to $15,685,124 in 1908. Most important are the manufacture of engines, boilers, metal-working machinery, wood-working machinery, pumping machinery, mining machinery and stoves, rank second among the state's manufactures; their value increased from $43,196,250 in 1890 to $61,872,635 in 1908. The output of the machine-product increased, and from $26,600,780 in 1900 to $28,729,049 in 1908. Clay products rank fifth in the state; they increased in value from $10,076,810 in 1905 to $26,166,305 in 1908. Boots and shoes rank sixth; their value increased from $17,920,575 in 1890 to $8,158,420 in 1908. Other leading manufactures are the manufacture of furniture ($11,902,693), paper and board (6,961,572), and refined petroleum ($10,498,864).

The greatest manufacturing centres are Cleveland, Cincinnati, Youngstown, Akron, Canton, Massillon, and Zanesville. The value of the products of these cities amounted to 57% of that for the entire state. A large portion of the iron and steel is manufactured in Cleveland, Youngstown, Steubenville, Belleura, Lorain, and Lucas counties. Nearly all of the value of the oil in Ohio is produced in Cleveland; most of the cash registers and calculating machines in Dayton; most of the rubber and elastic goods in Akron; nearly one-half of the hosiery and about three-fourths of the men's clothing in Cleveland; most of the shoes and women's clothing in Youngstown; and over two-thirds of the machinery in Toledo in flour and gist mill products; Springfield in agricultural implements; Cincinnati and Columbus in boots and shoes; Cleveland in women's clothing.

Ohio's State Government—The Ohio State Government is the most important natural means of transportation are the Ohio river on the S. border and Lake

1The statistics of 1895 were taken under the direction of the United States Census Bureau, but products other than those of the factory system, such, for example, as those of the hand trades, were excluded.
a population of 11,800 or more. The executive department consists of a governor, lieutenant-governor, secretary of state, auditor, treasurer and attorney-general. As a result of the dispute between Governor Arthur St Clair and the Territorial legislature, the constitution of 1802 conferred nearly all of the ordinary executive functions on the legislature. The governor's control over appointments was strengthened by the constitution of 1831 and by the subsequent creation of statutory offices, boards and commissions, but the right of veto was not given to him until the adoption of the constitutional amendments of 1903. The power as conferred at that time, however, is broader than usual, for it extends not only to items in appropriation bills, but to separate sections in other measures, and, in addition to the customary provision for passing a bill over the governor's veto by a two-thirds vote of each house it is required that the votes for repassage in each house must not be less than those given on the original passage. The governor is elected in November of even-numbered years for a term of two years. He is commander-in-chief of the state's military and naval forces, except when they are called into the service of the United States. He grants pardons and reprieves on the recommendation of the state board of pardons. If he die in office, resign or be impeached, the officers standing next in succession are the lieutenant-governor, the president of the Senate, and the speaker of the House of Representatives in the order named.

Members of the Senate and House of Representatives are elected for terms of two years; they must be residents of their respective counties or districts for one year preceding election, unless absent on public business of the state or of the United States. The ratio of representation in the Senate is obtained by dividing the total population of the state by thirty-five, the ratio in the House by dividing the population by one hundred. The membership in each house, however, is slightly above these figures, owing to a system of fractional representation and to the constitutional amendment of 1903 which allows each county at least one representative in the House of Representatives. The constitution provides for a reapportionment every ten years beginning in 1861. Biennial sessions are held beginning on the first Monday in January of the even-numbered years. The powers of the two houses are equal in every respect except that the Senate passes upon the governor's appointments and tries impeachment cases brought before it by the House of Representatives. The constitution prohibits special, local and retroactive legislation, legislation impairing the obligation of contracts, and legislation levying a poll tax for county or state purposes or a tax on state, municipal and public school bonds (amendment of 1903), and it limits the legislature to one term at a time. In addition it vests the control of public debts which the legislature may contract. The judicial department in 1910 was composed of a supreme court of six judges, eight circuit court1 of three judges each, ten districts (some with sub-divisions) of the common pleas court, the superior court of Cincinnati, probate courts, courts of insolventy in Cuyahoga and Hamilton counties, juvenile courts (established in 1904), justice of the peace courts and municipal courts. Under the constitution of 1802 judges were chosen by the legislature, but since 1831 they have been elected by direct popular vote—the judges of the supreme court being chosen at large. They are removable on complaint by a concurrent resolution approved by a two-thirds majority in each house of the legislature. The constitution provides that the terms of supreme and circuit judges shall be such even number of years not less than six as may be prescribed by the legislature; that the terms of the common pleas six years, that of the probate judges four years, that of other judges such even number of years not exceeding six as may be prescribed by the legislature—the statutory provision is six years—and that of justices of the peace such even number of years not exceeding four as may be thus prescribed—the statutory provision is four years.

Local Government.—The county and the township are the units of the rural, the city and the village the units of the urban local government. The chief county authority is the board of commissioners of three members elected for terms of two years. The other officials are the sheriff, treasurer and coroner, elected for two years; the auditor, recorder, clerk of courts, prosecuting attorney, surveyor, register of deeds, and the county auditor, elected by the board of school examiners (three) and the board of county visitors (six, of whom three are women); appointed usually by the probate judge for three years. The chief township authority is the board of trustees (three) and the treasurer (three) for terms of three years. In the parts of the state settled by people from New England township meetings were held in the early days, but their functions were gradually transferred to the trustees, and by 1820 the meetings had been given up almost entirely. The business of office holders are the clerk, treasurer, assessor, supervisor of roads, justices of the peace, constables, board of education and board of health. Under the provisions of the state constitution, the state auditor general is appointed by the legislature for a general law, and the legislature in 1852 enacted a "special municipal corporation act," the first of its kind in the United States. The system of classification adopted in time became so elaborate that many municipalities became isolated, each in a separate class, and the evils of special legislation were revived. Of the two chief cities, Cleveland (under a special act providing for the government of Columbus and Toledo, also) in 1892-1902 was governed under the federal plan, which centralized power in the hands of the mayor; in the council there was an almost hopeless diffusion of responsibility among the council and various executive boards. The supreme court in June 1902 decided that practically all the existing municipal legislation was unconstitutional, and the council subsequently adopted a new code. In 1890 a compromise between the Cleveland and the Cincinnati plans, with some additional features necessary to meet the conditions existing in the smaller cities. In order to comply with the court's interpretation of the constitution, municipal governments were divided into two classes, city and village, and the former having a population of five thousand or more; the chief officials in both cities and villages were the mayor, council, treasurer and numerous boards of commissioners. The council consists of at least seven and not more than nine members; that would apply to Cleveland, a city of 400,000 inhabitants, and to Painesville with its 5000 inhabitants. The code was replaced by the Paine Law of 1909, which provided for a board of control (something like a corporation council) consisting of seven members (the mayor and Toledo) of three members: the mayor and the directors (appointed and removable by the mayor) of two municipal departments—public service and public safety, the former including public works and municipal buildings and the latter the police and fire department. The mayor's appointments are many, and are seldom dependent on the consent of the council. A municipal civil service commission of three members (holding office for three years) is chosen by the council, which also elects the council clerk by subscribing to the oath; the council, and the president of the board of sinking fund commissioners; the pay (if any) of these commissions is set by each city. The city auditor, treasurer and solicitor are elected, as under the code.

In 1908 a direct primary law was passed providing for primary primaries, those of all parties in each district to be held at the same time (annually) and place, before the same election board, and at prices not more than three dollars for township and municipal officials and members of the school board; nominations to be by petition signed by at least 2% of the party voters of the political division, except that for United States senators 1 of 1% is the minimum. The law does not make the nomination of candidates for the United States Senate by this method mandatory nor such choice binding upon the General Assembly.

Legis.—The property rights of husband and wife are nearly equal; a wife cannot hold real estate in her own name, if single, and a widower or a widow is entitled to the use for life of one-third of the real estate of which his or her deceased consort was seized at the time of his or her death. Among the grounds on which a divorce may be obtained are adultery, desertion, extreme cruelty, extreme neglect of duty, habitual drunkenness, a former existing marriage, procurement of divorce without the state by one party, which continues marriage binding on the other, and imprisonment in a penitentiary for ten years. Either party may also bring an action for support against a deceased husband, a domestic or unmarried daughter, a homestead not exceeding $1000 in value, or personal property not exceeding $500 in value, is exempt from sale for the satisfaction of debts.

Charitable and Penal Institutions.—The state charitable and penal institutions are supervised by the board of charities and corrections, appointed by the governor, and local institutions by boards of county visitors of six members appointed by the probate judge. Each state institution in addition has its own board of trustees appointed by the governor, and each county infirmary is under the charge of three
infirmary directors chosen by popular vote. There are hospitals for the insane at Athens, Columbus, Dayton, Cleveland, Carthage (10 m. from Cincinnati; Longview Hospital), Massillon, Toledo and Lima; a hospital for epileptics at Galipolis, opened in 1893; institutions for the feeble-minded at Columbus and Massillon; (opened 1829) at Columbus; a state sanatorium for tuberculous patients at Mt. Vernon (opened 1909); an institution for crippled and deformed children (authorized in 1907); a soldiers' and sailors' orphans' home (authorized in 1876); a state asylum for insane (organized by the Republic); a home for soldiers, sailors, marines, their wives, mothers and widows, and army nurses at Madison (established by the National Women's Relief Corps; taken over by the state, 1904); and soldiers' and sailors' homes at the state, and at Dayton, supported by the United States. The state penal institutions are the boys' industrial school near Lancaster (established in 1854 as a Reform Farm), the girls' industrial home (1869) at Rutherford near Delaware, the reformatory at Mansfield (authorized 1884, opened 1896) and the penitentiary at Columbus (1815).

Education.—In 1785, Congress apportioned 5 sq. m. for the support of education. The public school system, however, was not developed until the 1830's, and then developed very slowly. The office of state commissioner of common schools was created in 1837, abolished in 1840 and revived in 1843. School districts fall into four classes—cities, villages, townships and school districts. The state maintains its public schools, and education is free and supported by a popular vote. Laws passed in 1877, 1893, 1899 and 1902 have made education compulsory for children of the ages of eight and twelve and for the state. School districts are created from the state's territorial homesteads, and the funds are derived by the state to satisfy purposes from a uniform levy of one mill on each dollar of taxable property in the state, from local levies (averaging 7.2 mills in township districts and 10.07 mills in separate districts) and from the state and local fund in excess of 1890, the revenues are paid by the state; Ohio University at Athens, founded in 1804, on the proceeds from grants by Congress to the Ohio Company; Miami University (chartered in 1809) at Oxford, which received the proceeds from a township granted by Congress in the South and was supported by the state and the federal government; and the University of Cincinnati, the first state university in the United States, was chartered by the state in 1819, and the only university in the state. The state created the Ohio State University in 1873; the University of Dayton at Dayton, the youngest university in the state, was chartered in 1850; and the University of Akron, the eighth state university, was chartered in 1876. The state has also created the University of Cincinnati, the University of Dayton, the University of Dayton, the University of Dayton, and the University of Dayton. The University of Dayton is the oldest university in the state.

Finance.—The revenues of the state are classified into four funds: the general revenue fund, the sinking fund, the state school fund and the university fund. The chief sources of the general revenue are taxes levied on personal property, land, tobacco, coal, and grain; the taxes on incomes; the taxes on the transfer of capital; the taxes on the transfer of capital and on the transfer of capital; and the taxes on the transfer of capital. The tax on the transfer of capital was imposed by the state in 1890, the tax on the transfer of capital was imposed by the state in 1890, and the tax on the transfer of capital was imposed by the state in 1890. The tax on the transfer of capital was imposed by the state in 1890. In 1845, the state legislature adopted a law taxing the state bank of Ohio, based on the model of the State Bank of Indiana of 1834. It became a guarantee of conservative banking, and was highly successful. There were at one time thirty-six banks. Most of the state institutions were founded after the establishment of the national banking system (1863-1864), but the high prices then discovered by the bondholders, and the fear of the failure of the state banks, led to a reaction, which was only partially checked by the reduction of the minimum capital to $25,000 under the currency act of the 14th of March 1890.

History.—Ohio was the pioneer state of the old North-West Territory, which embraced also what are now the states of Illinois, Indiana, Michigan, Ohio, Wisconsin, and the N.E. corner of Minnesota. When first discovered by the Spanish, and then by the French, in the first half of the 17th century, the territory included within what is now Ohio was mainly a battle-ground of numerous Indian tribes and the fixed abode of none except the Erie who occupied a strip along the border of Lake Erie. From the middle to the close of the 17th century the French were establishing a claim to the territory between the Great Lakes and the Ohio river by discovery and occupation, and although they had provoked the hostility of the Iroquois Indians they had helped the Wyandots, Miami and Shawnees to banish them from all territory W. of the Muskingum river. Up to this time the English had based their claim to the same territory on the discovery of the Atlantic Coast by the Cabots and upon the Virginia, Massachusetts and Connecticut charters under which these colonies extended westward to the Pacific Ocean. In 1701, New York, seeking another claim, obtained from the Iroquois a grant to the king of England of this territory which they claimed to have conquered but from which they had subsequently been expelled, and this grant was confirmed in 1730 and again in 1744.

About 1730 English traders from Pennsylvania, Maryland and Virginia began to visit the eastern and southern parts of the territory and the crisis approached as a French Canadian expedition under Clovis de la Borne took formal possession of the upper Ohio Valley by planting leaden plates at the mouths of the principal streams. This was in 1749 and in the same year George II. chartered the first Ohio Company, formed by Virginians and London merchants trading with Virginia for the purpose of colonizing the West. This company in 1750 sent Christopher Gist down the Ohio river to explore the country as far as the mouth of the Scioto river, and four years later the erection of a fort was begun in its interest at the forks of the Ohio. The French drove the English away and completed the fort (Fort Duquesne) for themselves. The Seven Years' War was the immediate consequence and this ended in the cession of the entire North-West to Great Britain. The former Indian allies of the French, however, immediately rose up in opposition to British rule and what is known as the Conspiracy of Pontiac (see PONTIAC), and the result of this was not completed until Colonel Henry Bouquet made an expedition (1764) into the valley of the Muskingum and there brought the Shawnees, Wyandots and Delawares to terms. With the North-West won from the French Great Britain no longer recognized those claims of her colonies to this territory which she had asserted against that nation, but in a royal proclamation of the 7th of October 1763 the granting of land W. of the Alleghenies was forbidden and on the 22nd of June 1774, parliament passed the Quebec Act which annexed the region to the province of Quebec. This was one of the grievances which brought on the War of Independence and during that war the North-West was won for the Americans by George Rogers Clark (q.v.). During that war also, those states which had no claims in the West contented that title to these western lands should pass to the Union and when the Articles of Confederation were submitted for ratification in 1777, Maryland refused to ratify them except on that condition. The result was that New York ceded its claim to the United States in 1780, Virginia in 1781, Massachusetts in 1785 and Connecticut in 1786. Connecticut, however, excepted a strip of land on Lake Erie for 120 m. and containing 3,250,000 acres. This strip, known as the Western Reserve, was ceded in 1800 on condition that Congress would guarantee the titles to land already granted by the state. Virginia reserved a tract between the Little Miami and Scioto rivers, known as the Virginia Military District for her soldiers in the War of Independence.
When the war was over and these cessions had been made, a great number of war veterans wished an opportunity to repair their broken fortunes in the West, and Congress, hopeful of receiving a large revenue from the sale of lands here, passed an ordinance on the 20th of May 1785 by which the present national system of land-surveys into townships 6 m. sq. was inaugurated in what is now S.W. Ohio in the summer of 1786. In March 1786 the second Ohio Company (q.v.), composed chiefly of New England officers and soldiers, was organized in Boston, Massachusetts, with a view to founding a new state between Lake Erie and the Ohio river. The famous North-West Ordinance was passed by Congress on the 13th of July 1787. This instrument provided a temporary government for the Territory with the understanding that, as soon as the population was sufficient, the representative system should be adopted, and later that states should be formed and admitted into the Union. There were to be not less than three nor more than five states. Of these the easternmost (Ohio) was to be bounded on the N., E. and S. by the Lakes, Pennsylvania and the Ohio river, and on the W. by a line drawn N. from the mouth of the Great Miami river to the Canadian boundary, if there were to be three states, or, if there were to be five, through the extreme S. bend of Lake Michigan, if there were to be five. Slavery was forbidden by the sixth article of the ordinance; and the third article read: "Religion, morality and knowledge being necessary to good government and the happiness of mankind, schools and the means of education shall for ever be encouraged." After the adoption of the North-West Ordinance the work of settlement made rapid progress. There were four main centres. The Ohio Company founded Marietta at the mouth of the Muskingum in 1788, and this is regarded as the oldest permanent settlement in the state. An association of New Jerseymen, organized by John Cleves Symmes, secured a grant from Congress in 1788-1792 to a strip of 248,540 acres on the Ohio between the Great Miami and the Little Miami, which came to be known as the Symmes Purchase. Their chief settlements were Columbia (1788) and Cincinnati (1789). The Virginia Military District, between the Scioto and the Little Miami, reserved in 1784 for bounties to Virginia continental troops, was colonized in large measure by people from that state. Their chief town was Chillicothe (1796). A small company of Connecticut people under Moses Cleaveland founded Cleveland in 1796 and Youngstown was begun a few years later, but that portion of the state made very slow progress until after the opening of the Ohio & Erie Canal in 1832.

During the Territorial period (1787-1803) Ohio was first a part of the unorganized North-West Territory (1787-1799), then a part of the organized North-West Territory (1799-1800), and then the organized North-West Territory (1800-1803). Indiana Territory having been detached from it on the W. in 1800. The first Territorial government was established at Marietta in July 1788, and General Arthur St Clair (1784-1815), the governor, had arrived in that month. His administration was characterized by the final struggle with the Indians and by a bitter conflict between the executive and the legislature, which greatly influenced the constitutional history of the state. The War of Independence was succeeded by a series of Indian uprisings. Two campaigns, the first under General Josiah Harmar (1775-1812) in 1790, and the second under General St Clair in 1791, failed on account of bad management and ignorance of Indian methods of warfare, and in 1793 General Anthony Wayne (q.v.) was sent out in command of a large force of regulars and volunteers. The decisive conflict, fought on the 20th of August 1794, near the rapids of the Maumee, is called the battle of Fallen Timbers, because the Indians concealed themselves behind the trunks of trees which had been felled by a storm. Wayne's dragoons broke through the brushwood, attacked the left flank of the Indians and soon put them to flight. In the treaty of Greenville (3rd August 1795) the Indians ceded their claims to the territory E. and S. of the Cuyahoga, the Tuscarawas, and an irregular line from Fort

Laurens (Bolivar) in Tuscarawas county to Fort Recovery in Mercer county, practically the whole E. and S. Ohio. The Jay Treaty was ratified in the same year, and in 1796 the British finally evacuated Detroit and the Maumee and Sandusky forts. By cessions and purchases in 1804, 1808 and 1817-1818 the state secured all of the lands of the Indians except their immediate homes, and these were finally exchanged for territory W. of the Mississippi. The last remnant migrated in 1841. General Wayne's victory was followed by an extensive immigration of New Englanders, of Germans, Scotch-Irish and Quakers from Pennsylvania, and of settlers from Virginia and Kentucky, many of whom came to escape the evils of slavery. This rapid increase of population led to the establishment of the organized Territorial government in 1799, to the restriction of that government in Ohio in 1800, and to the admission of the state into the Union in 1803.

The Congressional Enabling Act of the 30th of April 1802 followed that alternative of the North-West Ordinance which provided for five states in determining the boundaries, and in consequence the Indiana and Michigan districts were detached. A rigid adherence to the boundary authorized in 1787, however, would have resulted in the loss to Ohio of 476 sq. m. of territory in the N.W. part of the state, including the lake port of Toledo. After a long and bitter dispute—the Toledo War (see TOLEDO)—the present line, which is several miles N. of the bend of Lake Michigan, was definitely fixed in 1821, when Michigan came into the Union. (For the settlement of the eastern boundary, see PENNSYLVANIA.)

After having been temporarily at Marietta, Cincinnati, Chillicothe and Zanesville the capital was established at Columbus in 1816.

Since Congress did not pass any formal act of admission there has been some controversy as to when Ohio became a state. The Enabling Act was passed on the 30th of April 1802, the first state legislature met on the 1st of March 1803, the Territorial judges gave up their offices on the 15th of April 1803, and the Federal senates and representatives took their seats in Congress on the 17th of October 1803. Congress decided in 1806 in connexion with the payment of salaries to Territorial officials that the 1st of March 1803 was the date when state government began. Certainly the first session of the 21st Congress was held the lead of Tecumseh were again on the side of the British. Battles were fought at Fort Meigs (1813) and Fort Stephenson (Fremont, 1813) and Commodore Oliver Hazard Perry's naval victory on Lake Erie in 1813 was on the Ohio side of the boundary line.

Owing to the prohibition of slavery the vast majority of the early immigrants to Ohio came from the North, but, until the Mexican War forced the slavery question into the foreground, the Democrats usually controlled the state, because the principles of that party were more in harmony with frontier ideas of equality. The Whigs were successful in the presidential elections of 1836 and 1840, partly because of the financial panic and partly because their candidate, William Henry Harrison, was a "favourite son," and in the election of 1844, because of the unpopularity of the Texas issue. Victory was with the Democrats in 1848 and 1852, but since the organization of the Republican party in 1854 the state has uniformly given to the Republican presidential candidates its electoral votes. In the Civil War Ohio loyally supported the Union, furnishing 319,659 men for the armed forces. Dissatisfaction with the President's emancipation programme resulted in the election of a Democratic Congressional delegation in 1862, but the tide turned again after Gettysburg and Vicksburg; Clement L. Vallandigham, the Democratic leader, was deported from the state by military order, and the Republicans were successful in the elections of 1863 and 1864. A detachment of the Confederate cavalry under General John Morgan invaded the state in 1863, but was badly defeated in the battle of Buffington's Island (July 18th). Democratic governors were elected in 1873, 1877, 1883, 1889, 1905, 1908 and 1910. Five presidents have come from Ohio, William Henry Harrison, Rutherford B. Hayes, James A. Garfield, William McKinley, Jr., and William Howard Taft.
Governors of Ohio

Territorial Period (1783-1803).

Arthur St Clair 1787-1802 Federalist
Charles W. Byrd (Acting) 1802-1803 Dem.-Repub.

Period of Statehood.

Edward Tiffin 1803-1807 Dem.-Repub.
Samuel Kirk (Acting) 1807-1808
Sarah Huntington 1809-1811
Return Jonathan Meigs 1811-1814
Ohnien Looker (Acting) 1814-1815
Thomas Worthington 1815-1819
Ethan Allen 1819-1822
Allen Trimble (Acting) 1822-1823
Jeremiah Morrow 1823-1827 Democrat.
Allen Trimble 1827-1831
Duncan McArthur 1831-1834 Nat.-Repub.
Robert Lucas 1833-1837 Democrat.
Joseph Vance 1837-1839 Whig
Wilson Shannon 1839-1841 Democrat.
Thomas Corwin 1841-1843 Whig
Wilson Shannon 1843-1844 Democrat.
Thomas W. Bartley (Acting) 1844-1845
Moeulcey (Acting) 1845-1847
William Babb 1847-1849
Seabury Ford 1849-1851
Reuben Wood 1851-1853 Democrat.
William Medill (Acting, 1853) 1853-1856
Salome F. Chase 1856-1859
William Dennison, Jr. 1860-1862
David Tod 1862-1864
John Brough 1864-1866
Charles Anderson (Acting). 1866-1868
Jacob D. Cox 1868-1872
Rutherford B. Hayes 1872-1877
Edward F. Noyes. 1877-1878
William Allen 1874-1876 Democrat.
Rutherford B. Hayes 1876-1877 Republican
Thomas L. Young (Acting) 1877-1878
Richard M. Bishop 1878-1880 Democrat.
Charles Foster 1880-1884 Republican
George Hoadley 1884-1886 Democrat.
Joseph B. Foraker 1886-1890 Republican
James E. Campbell 1890-1892 Democrat.
William McKinley, Jr. 1892-1896 Republican
Asa Bushnell 1896-1899
George K. Nash 1899-1902
Myron T. Herrick 1902-1904
John M. Patterson 1904-1906
Arthur Linnert Harris 1906-1909 Republican
Judson Harmon 1909-1910

Ohio Company

A name of two 18th century companies organized for the colonization of the Ohio Valley. The first Ohio Company was organized in 1749, partly to aid in securing for the English control of the valley, then in dispute between England and France, and partly as a commercial project for trade with the Indians. The company was composed of Virginians, including Thomas Lee (d. 1750) and the two brothers of George Washington, Lawrence (who succeeded to the management upon the death of Lee) and Augustine; and of Englishmen, including John Hanbury, a wealthy London merchant. George II sanctioned a grant to the company of 500,000 acres generally N.W. of the Ohio, and to the eastward, between the Monongahela and the Kanawha rivers, but the grant was never actually issued. 1750-1755. The Virginia and North Carolina proprietors, except for the company the Ohio Valley as far as the mouth of the Scioto river. In 1752 the company had a pathway between the small fortified posts at Will's Creek (Cumberland), Maryland, and at Redstone Creek (Brownsville), Pennsylvania, which it had established in 1750; but it was finally merged in the Walpole Company (an organization in which Benjamin Franklin was interested), which in 1772 had received from the British government a grant of a large tract lying along the southern bank of the Ohio as far west as the mouth of the Scioto river. The War of Independence interrupted colonization and nothing was accomplished.

The second company, the Ohio Company of Associates, was formed at Boston on the 3rd of March 1756. The leaders in the movement were General Rufus Putnam, Benjamin Tupper (1758-1792), Samuel Holden Parsons (1737-1789) and Manasseh Cutler. Dr Cutler was selected to negotiate with Congress, and seems to have helped to secure the incorporation in the Ordinance for the government of the Northwest Territory of the paragraphs which set forth the provisions for the support of the militia and for the support of the ministry. Cutler's original intention was to buy for the Ohio Company only about 1,500,000 acres, but on the 27th of July Congress authorized a grant of about 5,000,000 acres of land for $3,500,000; a reduction of one-third was allowed for bad tracts, and it was also provided that the lands could be sold for in United States securities. On the 27th of October 1787 Cutler and Major Winthrop Sargent (1755-1820), who had joined him in the negotiations, signed two contracts; one was for the absolute purchase for the Ohio Company, at 66½ cents an acre, of 1,500,000 acres of land lying along the north bank of the Ohio river, from a point near the site of the

Abridged and History: P. G. Thomson's Bibliography of Ohio (Cincinnati, 1880) is an excellent guide to the study of Ohio's history. For archaeology see Cyrus Thomas's Catalogue of Prehistoric Works

1 Died in office.
OHIO RIVER, the principal eastern tributary of the Mississippi river, U.S.A. It is formed by the confluence of the Allegheny and Monongahela rivers at Pittsburgh, Pennsylvania, and flows N.W. nearly to the W. border of Pennsylvania, S.S.W. between Ohio and West Virginia, W. by N. between Ohio and Kentucky, and S.W. between Illinois and Indiana on the N. and Kentucky on the S. It is the largest of all the tributaries of the Mississippi in respect to the amount of water discharged (an average of about 15,800,000 cu. ft. per sec.), is first in importance as a highway of commerce, and in length (967 m.) as well as in the area of its drainage basin (approximately 210,000 sq. m.) it is exceeded only by the Missouri. The slope of the river at low water ranges from 1 ft. or more per mile in the upper section to about 0-75 ft. per mile in the middle section and 0-29 ft. per mile in the lower section, and the total fall is approximately 500 ft. Nearly two-thirds of the bed is occupied by 187 pools, in which the fall is very gentle; and the greater part of the descent is made over intervening bars, which are usually composed of sand or gravel but occasionally of hard pan or rock. The greatest falls are at Louisville, where the river within a distance of 2-25 m. descends 23-9 ft. over an irregular mass of limestone. The rock floor of the valley is usually 30 to 50 ft. below low water level, and when it comes to the surface, as it occasionally does, it extends at this height only part way across the valley. In the upper part of the river the bed contains much coarse gravel and numerous boulders, but lower down a sand bed prevails. The ordinary width of the upper half of the river is quite uniform, from 1200 to 1500 ft., but it widens in the pool above Louisville, contracts immediately below the Falls, and then gradually widens again until it reaches a maximum width of more than a mile about 20 m. from its mouth. Islands are numerous and vary in size from an acre or less to 5000 acres; above Louisville there are fifty or more, and below it about thirty. Many of them are cultivated.

Besides its parent streams, the Allegheny and the Monongahela, the Ohio has numerous large branches. On the N. it receives the waters of the Muskingum, Scioto, Miami and Wabash rivers, and on the S. those of the Kanawha, Big Sandy, Licking, Kentucky, Green, Cumberland and Tennessee rivers.

The drainage basin of the Ohio, in which the annual rainfall averages about 45 in., is, especially in the S. part of the river, of the "quick-spilling" kind, and as the swift mountain streams in that section are filled in February or March by the streams from the Gulf of Mexico, while the northern streams are swollen by melting snow and rain, the Ohio rises very suddenly and not infrequently attains a height of 30 to 50 ft. or more above low water level, spreads out ten to fifteen times its usual width, submerges the bottom lands, and often causes great damage to property in the lower part of the cities along its banks.

Robert Cavelier, Sieur de La Salle, asserted that he discovered the Ohio and descended it until his course was obstructed by a fall (thought to be the Falls at Louisville); this was probably in 1670, but until the middle of the next century, when its strategic importance in the struggle of the French and the English for the possession of the interior of the continent became fully recognized, little was generally known of it. By the treaty of 1763 ending the Seven Years’ War the English finally gained undisputed control of the territory along its banks. After Virginia had bought, in 1768, the claims of the Six Nations to the territory south of the Ohio, immigrants, mostly Virginians, began to descend the river in considerable numbers, but the Shawnee Indians, whose title to the land was more plausible than that of the Six Nations ever was, resisted their encroachments until the Shawnees were defeated in October 1774 at the battle of Point Pleasant. By the treaty of 1783 the entire Ohio country became a part of the United States and by the famous Ordinance of 1787 the north side was opened to settlement. Most of the settlers entered the region by the headwaters of the Ohio and carried much of their market produce, lumber, &c., down the Ohio and Mississippi to New Orleans or beyond. Until the successful navigation of the river by steamboats a considerable portion of the imports was carried overland from Philadelphia or Baltimore to Pittsburgh. The first steamboat on the Ohio was the "Ohio Rights," which was built in 1811 by Nicholas J. Roosevelt and sailed from Pittsburg to New Orleans in the same year, but it remained for Captain Henry M. Shreve (1785-1854) to demonstrate with the "Washington," which he built in 1816, the success of this kind of navigation on the river. From 1820 to the Civil War the steamboat system of inland navigation of the Ohio was a dominant factor in the industrial life of the Middle West. Cincinnati, Louisville and Pittsburgh on its banks were extensively engaged in building these vessels. The river was dotted with floating shops—dry-goods boats fitted with counters, boats containing a tinner's establishment, a blacksmith's shop, a factory, or a lottery office. Until the Erie Canal was opened in 1825 the Ohio river was the chief commercial highway between the East and the West. It was connected with Lake Erie in 1832 by the Ohio & Erie Canal from Portsmouth to Cleveland, and in 1845 by the Miami & Erie Canal from Cincinnati to Toledo.

In the natural state of the river navigation was usually almost wholly suspended during low water from July to November, and it was dangerous at all times on account of the numerous snags. The Federal government in 1827 undertook to remove the snags and to increase the depth of water on the bars by the construction of contraction works, such as dikes and wing dams, and appropriations for these purposes as well as for dredging were continued until 1844 and resumed in 1866; but as the channel obtained was less than 3 ft. in 1870, locks with movable dams—that is, dams that can be thrown down on the approach of a flood—were then advocated, and five years later Congress made an appropriation for constructing such a dam, the Davis Island Dam immediately below Pittsburg, as an experiment. This was opened in 1885 and was a recognized success; and in 1895 the Ohio Valley Improvement Association was organized in an effort to have the system extended. At first the association asked only for a channel 6 ft. in depth; and between 1896 and 1905 Congress authorized the necessary surveys and made appropriations for thirty-six locks and dams from the Davis Island Dam to the mouth of the Great Miami river. As the association then urged that the channel be made 9 ft. in depth Congress authorized the secretary of war to appoint a board of engineers which should make a thorough examination and report on the comparative merits of a channel 9 ft. in depth, and one 6 ft. in depth. The board reported in 1908 in favour of a 9-ft. channel and stated that fifty-four locks and dams would be necessary for such a channel throughout the course of the river, and Congress adopted this project. At the Falls is the Louisville & Portland Canal, originally built by a private corporation, with the United States as one of the stockholders, and opened in 1830, with a width of 50 ft., a length of 200 ft., and three locks, each with a lift of about 8 ft. In 1860-1872 the width was increased to 90 ft. and the three old locks were replaced by two new ones. The United States gradually increased its holdings of stock until in 1855 it became owner of all but five shares; it assumed the management of the canal in 1874, abolished tolls in 1880, and thereafter improved it in many respects. Sixty-eight locks and dams have been constructed on the principal tributaries, and the Allegheny, Monongahela, Cumberland, Tennessee, etc.
Muskingum, Kanawha, Little Kanawha, Big Sandy, Wabash, and Green now afford a total of about 900 m. of slack-water navigation.

See the Board of Engineers' Report of Examination of Ohio River with a view to obtaining Channel Depths of 6 and 9 ft. respectively (Washington, 1908); A. B. Hulbert, Waterways of Western Expansion (Cleveland, 1903) and The Ohio River, a Course of Empire (New York, 1906); also R. G. Thwaites, Afloat on the Ohio (New York, 1899).

OHLAU—ÖHLENSCHLÄGER

A. a published at the fantasy college Three of epic towards Copenhagen, the palace poet, 14th district churches, and a castle. It became a town in 1291 and passed to Prussia in 1742. In the 17th and 18th centuries it was often the residence of the dukes of Brieg and of the Sobielski family. See Schulz, Aus OHLAUS Vergangenheit (OHLAU, 1902).

ÖHLENSCHLÄGER, ADAM GOTTLOB (1779–1850), Danish poet, was born in Vesterbro, a suburb of Copenhagen, on the 14th of November 1779. His father, a Schlesiwyger by birth, was at that time organist, and later became keeper, of the royal palace of Frederiksborg; he was a very brisk and cheerful man. The other father, on the other hand, was partly German by extraction, suffered from depressed spirits, which afterwards deepened into melancholy madness. Adam and his sister Sofia were allowed their own way throughout their childhood, and were taught nothing, except to read and write, until their twelfth year. At the age of nine Adam began to make fluent verses. Three years later, while walking in Frederiksborg Gardens, he attracted the notice of the poet Edward Storm, and the result of the conversation was that he received a nomination to the college called “Posterior's High School,” an important institution of which Storm was the principal. Storm himself taught the class of Scandinavian mythology, and thus Öhleenschläger received his earliest bias towards the poetical religion of his ancestors. He was confirmed in 1795, and was to have been apprenticed to a tradesman in Copenhagen. To his great delight there was a hitch in the preliminaries, and he returned to his father's house. He now, in his eighteenth year, suddenly took up study with great zeal, but soon again abandoned his books for the stage, where a small position was offered him. In 1797 he actually made his appearance on the boards in several successive parts, but soon discovered that he possessed no real historical talent. The brothers Ørsted, with whom he had formed an intimacy fruitful of profit to him, persuaded him to quit the stage, and in 1800 he entered the university of Copenhagen as a student. He was doomed, however, to disturbance in his studies, first from the death of his mother, next from his invertebrate tendency towards poetry, and finally from the attack of the English upon Copenhagen in April 1801, which, however, inspired a dramatic sketch (April the Second 1801) which is the first thing of the kind by Öhleenschläger that we possess. In the summer of 1802, when Öhleenschläger had an old Scandinavian romance, as well as a volume of lyrics, in the press, the young Norse philosopher, Henrik Steffens, came back to Copenhagen after a long visit to Schelling in Germany, full of new romantic ideas. His lectures at the university, in which Goethe and Schiller were for the first time revealed to the Danish public, created a great sensation. Steffens and Öhleenschläger met one day at Dreier's Club, and after a conversation of sixteen hours the latter went home, suppressed his two coming volumes, and wrote at a sitting his splendid poem Guldhornene, in a manner totally new to Danish literature. The result of his new enthusiasm speedily showed itself in a somewhat hasty volume of poems, published in 1803, now chiefly remembered as containing the lovely piece called Sankt-Hansaften-Spil. The next two years saw the production of several exquisite works, in particular the epic of Thors Reise til Jutunheim, the charming poem in hexameters called Langelandsreisen, and the bewitching piece of fantasy Aladdin's Lampe (1805). At the age of twenty-six Öhleenschläger was universally recognized, even by the opponents of the romantic revival, as the leading poet of Denmark. He now collected his Poetical Writings in two volumes. He found no difficulty in obtaining a grant for foreign travel from the government, and he left his native country for the first time, joining Steffens at Halle in August 1805. Here he wrote the first of his great historical tragedies, Hakon Jarl, which he sent off to Copenhagen, and then proceeded for the winter months to Leipzig, where he associated with Humboldt, Fichte, and the leading men of the day, and met Goethe for the first time. In the spring of 1806 he went on to Weimar, where he spent several months in daily intercourse with Goethe. The autumn of the same year he spent with Tieck in Dresden, and proceeded in December to Paris. Here he resided eighteen months and wrote his three famous masterpieces, Baldur hin Gode (1808), Palnotake (1809), and Axel og Valborg (1810). In July 1808 he left Paris and spent the autumn and winter in Switzerland as the guest of Madame de Staël-Holstein at Coppet, in the midst of her circle of wits. In the spring of 1809 Öhleenschläger went to Rome to visit Thorwaldsen, and in his house wrote his tragedy of Correggio. He hurriedly returned to Denmark in the spring of 1810, partly to take the chair of aesthetics at the university of Copenhagen, partly to marry the sister-in-law of Rahbek, to whom he had been long betrothed. His first course of lectures dealt with his Danish predecessor Ewald, and was followed by Schiller. From this time forward his literary activity became very great; in 1811 he published the Oriental tale of Ali og Gulskynd, and in 1812 the last of his great tragedies, Stærkodder. From 1814 to 1819 he, or rather his admirers, were engaged in a long and angry controversy with Baggesen, who represented the old didactic school. This contest seems to have disturbed the peace of Öhleenschläger's mind, and to have undermined his genius. His talent may be said to have culminated in the glorious cycle of verse-romances called Helge, published in 1814. The tragedy of Hagbarth og-Signe, 1815, showed a distinct falling-off in style. In 1817 he went back to Paris, and published Hroars Saga and the tragedy of Fostbrodre. In 1818 he was again in Copenhagen, and wrote the idyll of Den lille Hyrdedreng and the Eddaic cycle called Nordens Guder. His next productions were the tragedies of Erik og Abel (1820) and Væringerne i Miklagård (1826), and the epic of Hrolf Krake (1829). It was in the last-mentioned that he, being in Sweden, associated with Humboldt, Fichte, and with a lawyer in front of the great altar of Lutheran Church by Bishop Essias Tegnér, as the "Scandinavian King of Song." His last volumes were Tordenskjold (1833), Dronning Margrethe (1833), Søbret (1835), Of den Hellige (1836), Knud den Store (1838), Dina (1842), Erik Glipping (1843), and Kiartan og Gudrun (1847). On his seventieth birthday, 14th November 1840, a public festival was arranged in his honour, and he was decorated by the king of Denmark under circumstances of great pomp. He died on the 20th of January 1850, and was buried in the cemetery of Frederiksborg. Immediately after his death his Recollections were published in two volumes.

With the exception of Holberg, there has been no Danish writer who has exercised so wide an influence as Öhleenschläger. His great work was to awaken in the breasts of his countrymen an enthusiasm for the poetry and religion of their ancestors, and this he performed to so complete an extent that his name remains to this day synonymous with Scandinavian romance. He supplied them with patriotic tragedies at the very moment when all eyes were turned to the stage, and when the old-fashioned pieces were felt to be inadequate. His plays, partly, no doubt, in consequence of his own early familiarity with acting, fulfilled the stage requirements of the day, and were popular beyond all expectation. The earliest are the best—Öhleenschläger's dramatic masterpiece being, without doubt his first tragedy, Hakon Jarl. In his poems and plays alike his style is limpid, elevated, profound; his flight is sustained at a high pitch without visible excitement. His fluent tenderness and romantic zest have been the secrets of his extreme popularity. Although his inspiration came from Germany, he is not much like a German poet, except when he is consciously following Goethe; his analogy is much rather to be found among the English poets.
his contemporaries. His mission towards antiquity reminds us of Scott, but he is, as a poet, a better artist than Scott; he has sometimes touches of exquise diction and of overwrought sensibility which remind us of Coleridge in us. In his wide ambition and profundness he possessed some characteristics of Southey, although his style has far more vitality. With all his faults he was a very great writer, and one of the principal pioneers of the romantic movement in Europe.

(E. G.)

OHLIGS, a town of Germany, in the Prussian Rhine Province, 17 m. by rail N. of Cologne, on the railway to Elberfeld. Pop. (1905) 24,264. Its chief manufactures are cutlery and hardware, and there are iron-foundries and flour-mills. Other industries are brewing, dyeing, weaving and brick-making. Before 1891 it was known as Merscheid.

OHM, GEORG SIMON (1787–1854). German physicist, was born at Erlangen on the 16th of March 1787, and was educated at the university there. He became professor of mathematics in the Jesuits' college at Cologne in 1817 and in the polytechnic school of Nuremberg in 1833, and in 1852 professor of experimental physics in the university of Munich, where he died on the 7th of July 1854. His writings were numerous, but, with one important exception, not original in his order. The exception is his pamphlet published in Berlin in 1827, with the title "Die elektrische Kette mathematisch bearbeitet." This work, the germ of which had appeared during the two preceding years in the journals of Schweiggin and Poggendorff, has exerted most important influence on the whole development of the theory and applications of current electricity, and Ohm's name has been incorporated in the terminology of electrical science. Nowadays "Ohm's Law," as it is called, in which all that is most valuable in the pamphlet is summarized, is as universally known as anything in physics. The equation for the propagation of electricity formed on Ohm's principles is identical with that of J. B. J. Fourier for the propagation of heat; and if, in Fourier's solution of any problem of heat-conduction, we change the word "temperature" to "potential" and write "electric current" instead of "flux of heat," we have the solution of a corresponding problem of electric conduction. The basis of Fourier's work was his clear conception and definition of conductivity. But this involves an assumption, undoubtedly true for small temperature increments, but still an assumption, viz., that, all else being the same, the flux of heat is strictly proportional to the gradient of temperature. An exactly similar assumption is made in the statement of Ohm's law, i.e. that, other things being alike, the strength of the current is at each point proportional to the gradient of potential. It happens, however, that with our modern methods it is much more easy to test the accuracy of the assumption in the case of electricity than in that of heat; and it has accordingly been shown by J. Clerk Maxwell and George Chrystal that Ohm's law is true, within the limits of experimental error, even when the currents are so powerful as almost to fuse the conducting wire.

Ohmmeter, an electrical instrument employed for measuring insulation-resistance or other high electrical resistances. For the purpose of measuring resistances up to a few thousand ohms, the most convenient appliance is a Wheatstone's Bridge, but when the resistance of the conductor to be measured is several hundred thousands ohms, or if it is the resistance of a so-called insulator, such as the insulating coating of the conductor wires employed for distributing electric current in houses and buildings for electric lighting, then the ohmmeter is more convenient. An ohmmeter in one form consists of two pairs of coils, one pair called the series coil and the other called the shunt coil. These coils are placed with their axes at right angles to one another, and at the point where the axes intersect a small pivoted needle of soft iron is placed, carrying a longer index needle moving over a scale.

Suppose it is desired to measure the insulation-resistance of a system of electric house wiring; the ohmmeter circuits are then joined up as shown in fig. 1, where W represents a portion of the wiring of the building and A portion of the insulating materials surrounding it. The object of the test is to discover the resistance of the insulator I, that is, to determine how much current flows through this insulator by leakage under a certain electromotive force or voltage which must not be less than that which will be employed in practice when the electric lights supplied through these wires are in operation. For this purpose the ohmmeter is provided with a small dynamo D, contained in a dynamo box which produces a continuous electromotive force of from 100 to 100 volts when the handle of the instrument is steadily turned. In making the test, the whole of the copper wires belonging to any section of the wiring and the insulator to be measured together at some point and then connected through the series coil of the ohmmeter with one terminal of the dynamo. The shunt coil S and the series coil Se are connected together at one point, and the remaining terminals of the dynamo and shunt coil must be connected to a "good earth," viz., generally the gas or water pipe or the building. In setting the dynamo in operation, a current passes through the shunt coil of the ohmmeter proportional to the voltage of the dynamo, and, if there is any sensible leakage through the insulation, it will be shown by the needle deflexion. If, however, the ohmmeter is connected to a "good earth," then the current will pass through the series coil proportional to the conductivity of the insulation of the wiring under the electromotive force used. These two coils, the shunt and the series coil, then produce two magnetic fields, with their lines of force at right angles to one another. The small pivoted needle is at first in a horizontal position, as placed by the common field therefore takes up a certain position, dependent on the relative value of these fields. The tangent of the angle of deflexion θ of this needle measured from its position, when the shunt coil is disconnected, is equal to the ratio of the magnetic forces of the two coils, and therefore the insulator, we call this last resistance R, the voltage of the working dynamo V, and the current through the insulator C, then tan θ = C/V = R. Hence the deflexion of the needle is proportional to the insulation resistance and the needle can be graduated to show directly this resistance in megohms.

The Eversheds and Vigneaux form of the instrument is much used in testing the insulation resistance of electric wiring in houses. In this instrument the dynamo and ohmmeter are combined in one instrument. The field magnet of the dynamo has two gaps in it. In one the exciting armature is rotated, producing the working voltage of 250, 500 or 1000 volts. In the other gap are pivoted two coils wound on an iron core placed at nearly a right angle to each other. One of these coils is in series with the armature circuit and with the insulation or high resistance to be measured. The other is a shunt across the terminals of the armature. When the armature is rotated, the two coils with a volta- meter connected to the terminals of the high resistance or insulator and the current passing through it, this, however, is measured on the insulation-resistance. Hence the instrument can be graduated to show this directly.

In the Naider ohmmeter the electrostatic principle is employed. The instrument consists of a high-voltage continuous current dynamo which creates a potential difference between the needle and the two quadrants of a quadrant electrometer (see Electro- meter). These two quadrants are interconnected by the high resistance to be measured, but therefore, themselves differ in potential. The exact position taken up by the needle is therefore determined by the potential difference (P.D.) of the quadrants and the P.D. of the needle and each quadrant, and, therefore, by the ratios of the P.D. of the quadrant and the currents in the insulated and the current passing through it, that is, by its insulation resistance.

The ohmmeter recommends itself by its portability, but in default of the possession of an ohmmeter the insulation-resistance can be measured by means of an ordinary mirror galvanometer (see Galvanometer) and insulated battery of suitable voltage. In this case one terminal of the battery is connected to the earth, and the other terminal if connected through the galvanometer with the copper wire, the insulation of which it is desired to test. If any sensible current flows through this insulator the galvanometer will show a deflexion.

The meaning of this deflexion can be interpreted as follows: If a galvanometer has a resistance R and is shunted by a shunt of resistance S, and the shunted galvanometer is placed in series with a large resistance R' of the order of a megohm, and if the same
battery is applied to the shunted galvanometer, then the current $C$ passing through the galvanometer will be given by the expression

$$C = \frac{R'}{(R+S) + R'S'}$$

where $V$ is the electromotive force of the battery. It is possible so to arrange the value of the shunt and of the high resistance $R'$ that the same or nearly the same deflection of the galvanometer is obtained as when it is used in series with the battery and the insulation-resistance. In these circumstances the current through the galvanometer is known, provided that the voltage of the battery is determined by means of a potentiometer (g.e.). Hence the resistance of the insulator can be ascertained, since it is expressed in ohms by the ratio of the voltage of the battery in ohms to the current through the galvanometer in amperes. In applying this method to test the insulation of india-rubber-covered or oil insulated copper wire, before employing the wire for electrical purposes, it is usual to place the coil of wire W (fig. 2) in an insulated tank of water T, which is connected to one terminal of the insulated battery B, the other terminal being connected to a metallic conductor CC of the wire under test, through a galvanometer G. To prevent leakage over the surface of the insulating covering of the wire which projects above the surface of the water, it is necessary to employ a "guard wire" P, which consists of a piece of fine copper wire, twisted round the extremity of the insulated wire and connected to the battery. This guard wire prevents any current which leaks over the surface of the insulator from passing through the galvanometer G, and the galvano-meter to the indication is therefore only determined by the amount of current which passes through the insulator, or by its insulation-resistance.

of from 0.700 to 0.730 specific gravity showed that 98% of the lighter sample distilled over below 120° C, while only 88% of the heavier came over within the same temperature range. The heavier petrol is not so easily converted into vapour. The great modern development of the motor car gives the light oil engine a much more important place as one of the leading sources of motive power in the world. The total petrol power now applied to cars on land and to vessels on sea amounts to at least two million H.P. The petrol engine has also enabled aeroplanes to be used in practice.

The earliest proposal to use oil as a means to produce motive power was made by an English inventor—Street—in 1794, but the first practical petroleum engine was that of Julius Hock of Vienna, produced in 1870. This engine, like Lenoir’s gas engine, operated without compression. The piston took in a charge of air and light petroleum spray which was ignited by a flame jet and produced a low-pressure explosion. Like all non-compression engines, Hock’s machine was very cumbersome and gave little power. In 1873, Brayton, an English engineer, had settled in America, produced a light oil engine working on the constant pressure system without explosion. This appears to have been the earliest compression engine to use oil fuel instead of gas.

Shortly after the introduction of the “Otto” gas engine in 1876, a motor of this type was operated by an inflammable vapour produced by passing air on its way to the cylinder through the light oil then known as gasoline. A further air supply was drawn into the cylinder to form the required explosive mixture, which was subsequently compressed and ignited in the usual way. The Spiel petroleum engine was the first Otto cycle motor introduced into practice which dispensed with an independent vaporizing apparatus. Light hydrocarbon of a specific gravity of not greater than 0.725 was injected directly into the cylinder on the suction stroke by means of a pump. In entering it formed spray mixed with the air, was vaporized, and on compression an explosion was obtained just as in the gas engine.

Until the year 1883 the different gas and oil engines constructed were of a heavy type rotating at about 150 to 250 revolutions per minute. In that year Daimler conceived the idea of constructing very small engines with light moving parts, in order to enable them to be rotated at such high speeds as 800 and 1000 revolutions per minute. At that time engineers did not consider it practicable to run engines at such speeds; it was supposed that low speed was necessary to durability and smooth running. Daimler showed this idea to be wrong by producing his first small engine in 1883. In 1886 he made his first experiment with a motor bicycle, and on the 4th of March 1887 he ran for the first time a motor car propelled by a petrol engine. Daimler deserves great credit for realizing the possibility of producing durable and effective engines rotating at such unusually high speeds; and, further, for proving that his ideas were right in actual practice. His little engines contained nothing new in their cycles of operation, but they provided the first step in the startlingly rapid development of petrol motive power which we have seen in the last twenty years. The high speed of rotation enabled motors to be constructed giving a very large power for a very small weight.

Fig. 1 is a diagrammatic section of an early Daimler motor. A is the cylinder, B the piston, C the connecting rod, and D the crank-case which is entirely enclosed in a casing. A further lever is carried by the crank-shaft, and it serves the double purpose of a fly-wheel and a clutch. a is the combustion space, E the single port, which serves both for inlet of the charge and for discharge of exhaust. W is inlet valve, F the charging valve, which was supposed in its action, and is held closed by a spring f; G the carburettor, H the igniter tube, I the igniter tube lamp, K the charge inlet passage, L the air filter chamber, and M an adjustable air inlet cap for regulating the air inlet area. The light oil—petrol, as it is commonly called—is fed to the float chamber N of the vaporizer by means of the valve O. So long as the level of the petrol is high, the float r, acting by levers about it, holds the valve O closed against oil forced by air pressure along the pipe P. When the level falls, however, the valve opens and more petrol is admitted. When the piston B makes its suction stroke, air passes from the atmosphere by the passage K through the valve F, which it opens automatically. The pressure falls within the passage K, and a spur of petrol passes by the jet G, separate air at the same time passing by the passage K round the jet. The petrol breaks up into spray by impact against the walls of the passage K, and it vaporizes and passes into the cylinder A as an inflammable mixture. When the piston B returns it compresses the charge into a, and upon compression the incandescent igniter tube H fires the charge. H is a short platinum tube, which is always open to the compression space. It is rendered incandescent by the burner J, fed with petrol from the pipe supplying the vaporizer. The open incandescent tube is found to act well for small engines, and it does not ignite the charge until the compression takes place, because the inflammable mixture cannot come into contact with the hot part till it is forced up the tube by the compression. The engine is started by giving the crank-shaft a smart turn round by means of a detachable handle. The exhaust is alone actuated from the valve shaft. The shaft Q is operated by pinion and a spur-wheel Q' at half the rate of the crank-shaft. The governing is accomplished by cutting out explosions as with the gas engine, but the governor operates by preventing the exhaust valve from opening, so that no charge is discharged from the cylinder, and therefore no charge is drawn in. The cam R operates the exhaust valve, the levers shown are so controlled by the governor (not shown) that the knife edge S is pressed out when speed is too high, and cannot engage the recess T until it falls. The engine has a water jacket V, through which water is circulated. Cooling devices are used to economize water.

Benzen of Mannheim followed close on the work of Daimler, and in France Panhard and Levassor, Peugeot, De Dion, Delahaye and Renault all contributed to the development of the petrol engine, while Napier, Lanchester, Royce and Austin were the most prominent among the many English designers.

The modern petrol engine differs in many respects from the Daimler engine just described both as to general design, method of carburett ing, igniting and controlling the power and speed. The carburettor now used is usually of the float and jet type shown in fig. 1, but alterations have been made to
allow of the production of uniform mixture in the cylinder under widely varying conditions of speed and load. The original form of carburettor was not well adapted to allow of great
change of volume per suction stroke. Tube ignition has been abandoned, and the electric system is now supreme. The favourite type at present is that of the high-tension magneto.

Valves are now all mechanically operated; the automatic inlet valve has practically disappeared. Engines are no longer controlled by cutting out impulses; the governing is effected by throttling the charge, that is by diminishing the volume of charge admitted to the cylinder at one stroke. Broadly, throttling by reducing charge weight reduces pressure of compression and so allows the power of the explosion to be graduated within wide limits while maintaining continuity of impulses.

The object of the throttle control is to keep up continuous impulses for each cycle of operation, while graduating the power produced by each impulse so as to meet the conditions of the load.

Originally three types of carburettor were employed for dealing with light oil; first, the surface carburettor; second, the wick carburettor; and third, the jet carburettor. The surface carburettor has entirely disappeared. In it air was passed over a surface of light oil or bubbled through it; the air carried off a vapour to form explosive mixture. It was found, however, that the oil remaining in the carburettor gradually became heavier and heavier, so that ultimately no proper vaporization took place. This was due to the fractional evaporation of the oil which tended to carry away the light vapours, leaving in the vessel the oil, which produced heavy vapours. To avoid this fractionation the wick carburettor was introduced and here a complete portion of oil was vaporized at each operation so that no concentration of heavy oil was possible. The wick carburettor is still used in some cars, but the jet carburettor is practically universal. It has the advantage of discharging separate portions of oil into the air entering the engine, each portion being carried away and evaporated with all its fractions to produce the charge in the cylinder.

The modern jet carburettor appears to have originated with Butler, an English engineer, but it was first extensively used in the modification produced by Maybach as shown in fig. 1.

A diagrammatic section of a carburettor of the Maybach type is shown in a larger scale in fig. 2.

Petrol is admitted to the chamber A by the valve B which is controlled by the float C acting through the levers D, so that the valve E is opened so as to allow the required volume of petrol to flow into the jet F, which is constructed to a sufficient extent to produce the pressure necessary to propel the petrol through the jet G, and the area of the discharge aperture of the petrol jet E is proportioned to give the desired volume of petrol to form the proper mixture with air. The device in this form works quite well when the range of speed required from the engine is not great; that is, within limits, the volume of petrol thrown by the jet is fairly proportional to the speed of the engine. When, however, the speed range is greater, such as in modern motors, which may vary from 300 to 1500 revolutions per minute under light and heavy loads, then it becomes impossible to secure proportionality sufficiently accurate for regular ignition. This implies not only a change of engine speed but a change of volume entering the cylinder at each stroke determined by the position of the throttle. This introduces further complications. Throttle control implies a change of total charge volume per stroke, which change may occur either at a low or at a high speed.

To meet this change the petrol jet should respond in such manner as to give a constant proportionality of petrol weight to air weight throughout all the variations—otherwise sometimes petrol will be present in excess with no oxygen to burn it, and at other times the mixture may be so dilute as to miss firing altogether.

To meet these varying conditions many carburettors have been produced which seek by various devices to maintain uniformity of quality of mixture by the automatic change of throttle a round the jet.

Fig. 3 shows in diagrammatic section one of the simplest of these contrivances, known as the Krebs carburettor. The petrol enters from the float chamber to the jet E; and, while the engine is running slowly, the whole supply of air enters by way of the passage F, mixes with the petrol and reaches the cylinders by way of the pipe G. The volume of charge entering the cylinder per stroke is controlled by the piston H operated by the rod I; and so long as the charge volume required remains small, air from the atmosphere enters only by F. When speed rises, however, and the throttle is sufficiently opened, the pressure within the apparatus falls and affects the spring-pressed diahram K, which actuates a piston valve controlling the air passages L so that this valve opens to the atmosphere more and more with increasing pressure reduction, and additional air thus flows into the carburettor and mixes with the petrol entering through F. By this device the required proportionality is maintained through a comparatively large volume range. This change of air admission is rendered necessary because of the difference between the laws of air and petrol flow. In order to give a sufficient weight of petrol at low speeds when the drop is small, it is necessary to provide a somewhat large area of petrol jet. When suction increases owing to high speed, this large area discharges too much petrol, and so necessitates a device, such as that described, which admits more air.

A still simpler device is adopted in many carburettors—that of an additional air inlet valve, kept closed until wanted by a spring.

Fig. 4 shows a diagrammatic section as used in the Vauxhall carburettor. Here the petrol jet and primary and secondary air passages are lettered as before.

The same effect is produced by devices which alter the area of the petrol jet or increase or diminish the number of petrol jets exposed as required. Although engine designers have succeeded in producing engines of great speed and power, no one has been able to devise a range of speed and charge demand, so as to obtain effective power expansion at all these conditions, yet much remains to be done to secure constancy of mixture at all speeds. Notwithstanding much which has been said as to varying mixture, there is only one mixture of air and petrol which gives the best results—that is, in which there is some excess of oxygen, more than sufficient to burn all the hydrogen and carbon present. It is necessary to secure this mixture under all conditions, not only to obtain economy in running but also to maintain purity of exhaust gases. Moreover, it is desirable in all these cases that the exhaust gases should be burned at the lowest possible temperature in order to get rid of any surplus quantities of carbonic oxide into the atmosphere with their exhaust gases, and some discharge so as to give rise to danger in a closed garage. Carbonic oxide is an extremely poisonous gas which would be fatal to human beings in the interests of the health of our large cities. The enormous increase of motor traffic makes it important to render the exhaust gases as pure and innocuous as possible. Tests were made by the Royal Automobile Club some years ago which clearly showed that carbonic oxide should be kept down to 2% and under when carburettors were properly adjusted. Subsequent experiments have been made by Hopkinson, Clerk and
OIL ENGINE

Watson, which clearly prove that in some cases as much as 30% of the whole heat of the petrol is lost in the exhaust gases by imperfect combustion. This opens a wide field for improvement, and makes it probable that with better carburettors motor cars would not only discharge pure exhaust gases but would work on very much less petrol than they do at present.

Practically all modern petrol engines are controlled by throttling the whole charge. In the earlier days several methods of control were attempted: (1) missing impulses as in fig. 1 of the Daimler engines; (2) altering the timing of spark; (3) throttling petrol supply, and (4) throttling the mixture of petrol and air. The last method has proved to be the best. By maintaining the proportion of explosive mixture, but diminishing the total volume admitted to the cylinder per stroke, graduated impulses are obtained without any, or but few, missed ignitions. The effect of the throttling is to reduce compression by diminishing total charge weight. To a certain extent the proportion of petrol to total charge also varies, because the residual exhaust gases remain constant through a wide range. The thermal efficiency diminishes as the throttling increases; but, down to a third of the brake power, the diminution is not great, because although compression is reduced the expansion remains the same. At low compressions, however, the engine works practically as a non-compression engine, and the point of maximum pressure becomes greatly delayed. The efficiency, therefore, falls markedly, but this is not of much importance at light loads. Experiments by Callendar, Hopkinson, Watson and others have proved that the thermal efficiency obtained from these small engines with the throttle full open is very high indeed; 28% of the whole heat in the petrol is often given as indicated work when the carburettor is properly adjusted. As a large gas engine for the same compression cannot do better than 35%, it appears that the loss of heat due to small dimensions is compensated by the small time of exposure of the gases of explosion due to the high speed of rotation. Throttle control is very effective, and it has the great advantage of diminishing maximum

pressures to which the piston and cylinders are exposed while the engine is running at the lower loads. This is important both for smooth running and good wearing qualities. Theoretically, better results could be obtained from the point of view of economy by retaining a constant compression pressure, constant charge of air, and producing ignition, somewhat in the manner of the Diesel engine. Such a method, however, would have the disadvantage of producing practically the same maximum pressure for all loads, and this would tend to give an engine which would not work smoothly at low speeds.

As has been said, tube ignition was speedily abandoned for electric ignition by accumulator, induction coil distributor and sparking plug. This in its turn was largely displaced by the low-tension magneto system, in which the spark was formed between contacts which were mechanically separated within the cylinders. The separable contacts gave rise to complications, and at present the most popular system of ignition is undoubtedly that of the high-tension magneto. In this system the ordinary high-tension sparking plugs are used, and the high-tension current is generated in a secondary winding on the armature of the magneto, and reaches the sparking plugs by way of a rotary distributor. In many cases the high-tension magneto system is used for the ordinary running of the engine, combined with an accumulator or battery and induction coil for starting the engine from rest. Such systems are called dual ignition systems. Sometimes the same ignition plugs are adapted to spark from either source, and in other cases separate plugs are used. The magneto systems have the great advantage of generating current without battery, and by their use noise is reduced to a minimum. All electrical systems are now arranged to allow of advancing and retarding the spark from the steering wheel. In modern magneto methods, however, the spark is automatically retarded when the engine slows and advanced when the speed rises, so that less change is required from the wheel than is necessary with battery and coil.

Sir Oliver Lodge has invented a most interesting system of electric ignition, making use of the production of an extra oscillatory current of enormous tension produced by the combined use of spark gap and condenser. This extra spark passes freely even under water, and it is impossible to stop it by any ordinary sooting or fouling of the ignition plug.

The most popular engines are now of the four and six-cylinder types.

Fig. 5 shows a modern four-cylinder engine in longitudinal and transverse sections as made by the Wolseley Company. A, A are the cylinders; B, B, water jackets; G, oil scoops on the large ends of the connecting-rods. These scoops take up oil from the crank chamber. Forced lubrication is used. The oil pump M is of the toothed wheel type, and it is driven by skew gearing. An oil sump is arranged at L, and the oil is pumped from this sump by the pump described. The overflow from the main bearings supplies the channels in the crank case from which the oil scoops take their charge. It will be seen that the two inside pistons are attached to cranks of coincident centres, and this is true of the two outside pistons also. This is the usual arrangement in four-cylinder engines. By this device the primary forces are balanced; but a small secondary unbalanced force remains, due to the difference in motion of the pistons in the up and down portions of their stroke. A six-cylinder engine has the advantage of getting rid of this secondary unbalanced force; but it requires a longer and more rigid crank chamber. In this engine the inlet and exhaust valves of each cylinder are placed in the water jacket and are driven from one camshaft. This is a very favourite arrangement; but many engines are constructed in which the inlet and exhaust valves operate on opposite sides of the cylinder in separate ports and are driven from separate camshafts. Ignition is applied to this engine; that is, an ignition composed of high-tension magneto and also battery and coil for starting. U is the high-tension magneto. Under the figure there is shown a list of parts which sufficiently indicate the nature of the engine.

An interesting and novel form of engine is shown at fig. 6. This is a well-known engine designed by Mr Knight, an American inventor, and now made by the Daimler and other companies. It will be observed in the figure that the ordinary lift valves are entirely dispensed with, and slide valves are used of the cylindrical shell type. The engine operates on the ordinary Otto cycle, and all the valve actions necessary to admit charge and discharge exhaust gases are accomplished by means of two sleeves sliding one within the other.
cross the Channel was accomplished by means of an Anzani engine, and the Gnome engine, because it was used in the aeroplane with which Paulhan flew from London to Manchester.

Fig. 7 shows transverse and longitudinal sections through the Anzani motor. Looking at the longitudinal section it will be observed that the cylinders are of the air-cooled type; the exhaust valves alone are positively operated, and the inlet valves are of the automatic lift kind. The transverse section shows that three radially arranged cylinders are used and three pistons act upon one crank-pin. The Otto cycle is followed so that three impulses are obtained for every two revolutions. The cylinders are spaced apart 60° and project from the upper side of the crank chamber. Although not shown in the drawing, the pistons overrun a row of holes at the out end of the stroke and the exhaust first discharges through these holes. This is a very common device in aeroplane engines, and it greatly increases the rapidity of the exhaust discharged and reduces the work falling upon the exhaust valve. The pistons and cylinders are of cast iron; the rings are of cast iron; the ignition is electric, and the petrol is fed by gravity. The engine used by Blériot in his Cross-Channel flight was 25 H.P., cylinders 105 mm. bore X 130 mm. stroke; revolutions, 1600 per minute; total weight, 145 lb. The engine, it will be seen, is exceedingly simple, although air-cooling seems somewhat primitive for anything except short flights. The larger Anzani motors are water-cooled.

A diagrammatic transverse section of the Gnome motor is shown at fig. 8. In this interesting engine there are seven cylinders disposed radially round a fixed crank-shaft. The seven pistons are all connected to the same crank-shaft, one piston being rigidly connected to a big end of peculiar construction by a connecting-rod, while the other connecting-rods are linked on to the same big end by pins; that is, a hollow fixed crank-shaft has a single throw to which only one connecting-rod is attached; all the other connecting-rods work on pins let into the big end of that connecting-rod. The cylinders revolve round the fixed crank in the manner of the well-known engines first introduced to practice by Mr John Rigg. The explosive mixture is fed from the carburettor through the hollow crank-shaft into the crank-case, and it is admitted into the cylinders by means of automatic inlet valves placed in the heads of the pistons. The exhaust valves are arranged on the cylinder heads. Dual ignition is provided by high tension magneto and storage battery and coil. The cylinders are ribbed outside like the Anzani, and are very effectively air-cooled by their rotation through the air as well as by the passage of the aeroplane through the atmosphere. The cylinders in the 35 H.P. motor are 110 mm. bore X 120 mm. stroke. The speed of rotation is usually 1200 revolutions per minute. The total weight of the engine complete is 180 lb, or just over 9 lb per brake horse-power. The subject of aeroplane petrol engines is a most interesting one, and rapid progress is being made.

So far, only 4-cycle engines have been described, and they are almost universal for use in motor-cars and aeroplanes. Some motor cars, however, use 2-cycle engines. Several types follow the “Clerk” cycle (see Gas Engine) and others the “Day” cycle. In America the Day cycle is very popular for motor launches, as the engine is of a very simple, easily managed kind. At present, however, the two-cycle engine has made but little way in motor car or aeroplane work. It is capable of great development and the attention given to it is increasing.

So far, petrol has been alluded to as the main liquid fuel for these motors. Other hydrocarbons have also been used; benzol, for example, obtained from gas tar is used to some extent, and alcohol has been applied to a considerable extent both for stationary and locomotive engines. Alcohol, however, has not been entirely successful. The amount of heat obtained for a given monetary expenditure is only about half that obtained by means of petrol. On the continent of Europe, however, alcohol motors have been considerably used for public vehicles.

The majority of petrol motors are provided with water jackets around their cylinders and combustion spaces. As only a small quantity of water can be carried, it is necessary to cool the water as fast as it becomes hot. For this purpose radiators of various constructions are applied. Generally a pump is used to produce a forced circulation, discharging the hot water from the engine jackets through the radiator and returning the cooled water to the jackets at another place. The radiators consist in some cases of fine tubes covered with projecting fins or gills; the motion of the car forces air over the exterior of those surfaces and is assisted by the operation of a powerful fan driven from the engine. A favourite form of radiator consists of numerous small tubes set into a casing and arranged somewhat like a steam-engine condenser. Water is forced by the pump round these tubes, and air passes from the atmosphere through them. This type of radiator is sometimes known as the “honeycomb”
radiator. A very large cooling surface is provided, so that the same water is used over and over again. In a day's run with a modern petrol engine very little water is lost from the system. Some engines dispense with a pump and depend on what is called the thermo-syphon. This is the old gas-engine system of circulation, depending on the different density of water when hot and cool. The engine shown at fig. 5 is provided with a water-circulation system of this kind. For the smaller engines the thermo-syphon works extremely well.

Heavy oil engines are those which consume oil having a flashing-point above 73° F.—the minimum at present allowed by act of parliament in Great Britain for oils to be consumed in ordinary illuminating lamps. Such oils are American and Russian petroleum and Scottish paraffins. They vary in specific gravity from .78 to .85, and in flashing-point from 75° to 152° F. Engines burning such oils may be divided into three distinct classes: (1) Engines in which the oil is subjected to a spraying operation before vaporization; (2) Engines in which the oil is injected into the cylinder and vaporized within the cylinder; (3) Engines in which the oil is vaporized in a device external to the cylinder and introduced into the cylinder in the state of vapour.

The method of ignition might also be used to divide the engines into those igniting by the electric spark, by an incandescent tube, by compression, or by the heat of the internal surfaces of the combustion space. Spiel's engine was ignited by a flame igniting device similar to that used in Clerk's gas engine, and it was the only one introduced into Great Britain in which this method was adopted, though on the continent flame igniters were not uncommon. Electrically-operated igniters have come into extensive use throughout the world.

The engines first used in Great Britain which fell under the first head were the Priestman and Samuelson, the oil being sprayed before being vaporized in both. The principle of the spray producer used is that so well and so widely known in connexion with the atomizers or spray producers used by perfumers. Fig. 9 shows such a spray producer in section. An air blast passing from the small jet A crosses the top of the tube B and creates within it a partial vacuum. The liquid contained in C flows up the tube B and issuing at the top of the tube through a small orifice is at once blown into very fine spray by the action of the air jet. If such a scent distributor be filled with petroleum oil, such as Royal Daylight or Rousline, the oil will be blown into fine spray, which can be ignited by a flame and will burn, if the jets be properly proportioned, with an intense blue non-luminous flame. The earlier inventors often expressed the idea that an explosive mixture could be prepared without any vaporization whatever, by simply producing an atmosphere containing inflammable liquid in extremely small particles distributed throughout the air in such proportion as to allow of complete combustion. The familiar explosive combustion of lycopodium, and the disastrous explosions caused in the exhaust rooms of flour-mills by the presence of finely divided flour in the air, have also suggested to inventors the idea of producing explosions for power purposes from a suitable soluble liquid, though, doubtless, explosions could be produced in that way, yet in oil engines the production of spray is only a preliminary to the vaporization of the oil. If a sample of oil is sprayed in the manner just described, and injected in a hot chamber also filled with hot air, it at once passes into a state of vapour within that chamber, even though the air be at a temperature far below the boiling-point of the oil; the spray producer, in fact, furnishes a ready means of saturating any volume of air with heavy petroleum oil to the full extent possible from the vapour tension of the oil at that particular temperature. The oil engines described below are in reality explosion gas engines of the ordinary Otto type, with special arrangements to enable them to vaporize the oil to be used. Only such parts of them as are necessary for the treatment and ignition will therefore be described.

Fig. 10 is a vertical section through the cylinder and vaporizer of a Priestman engine, and fig. 11 is a section on a larger scale, showing the vaporizing jet and the air admission and regulation valve leading to the vaporizer. Oil is forced by means of air pressure from a reservoir through a pipe to the spraying nozzle a, and air passes from an accessory pump through the annular channel 6 into the cylinder, and there meets the oil jet issuing from a. The oil is thus broken up into spray, and the air charged with spray flows into the vaporizer E, which is heated up in the first place on starting the engine by means of a lamp. In the vaporizer the oil spray becomes oil vapour, saturating the air within the hot walls. On the opening-stroke of the piston the mixture passes by way of the inlet valve H into the cylinder, air flowing into the vaporizer to replace it through the valve I (fig. 11). The cylinder K is thus charged with a mixture of air and thus saturated with vapour some of which may exist in the form of very fine spray. The piston L then returns and compresses the mixture, and when the compression is quite complete an electric spark is passed between the points M, and a compression explosion is obtained precisely similar to that obtained in the gas engine. The piston moves out, and on its return stroke the exhaust valve N is opened and the exhaust gases discharged by way of the pipe O, round the jacket P, enclosing the vaporizing chamber. The latter is thus kept hot by the exhaust gases when the engine is at work, and it remains sufficiently hot without the use of the lamp provided for starting. To obtain the electric spark a bi-chromate battery is used, an eccentric rod, used to actuate the exhaust valve and the air-pump for supplying the oil chamber and the spraying jet. To start the engine a hand pump is worked until the pressure is sufficient to force the oil through the spraying nozzle, and oil spray is formed in the starting lamp; the spray and air mixed produce a blue flame which heats the vaporizer. The fly-wheel is then rotated by hand and the engine moves away. The eccentric shaft is driven from the crank-shaft by means of toothed wheels, which reduce the speed to one-half the revolutions of the crank-shaft. The charging inlet valve is automatic. Governing is effected by throttling the oil and air supply. The governor operates on the butterfly valve T (fig. 11), and on the plug-cock T connected to it, by means of the spindle %.

Fig. 11.—Priestman Oil Engine (section on a larger scale).

XX. 2 a
The compression pressure of the mixture before admission is, however, 
steadily reduced as the load is reduced, and at very light loads the 
engine is running practically as a non-compression engine.

A test by Professor Unwin of a 43 nominal horse-power Priestman 
engine, cylinder 8\(\frac{1}{2}\) in. diameter, 12 in. stroke, normal speed 180 
revolutions per minute, showed the consumption of oil per indicated 
horse-power hour to be 1-66 lb and per brake horse-power hour 1-243 lb. 
The oil used was that known as Broxburn Lighthouse, a 
Scottish paraffin oil produced by the destructive distillation 
of coal, and costing a density of 81 and a flashing-point of 152\(^o\) F.

With a 5 H.P. engine of the same dimensions, the volume swept by 
the piston per stroke being 395 cub. ft. and the clearance space in 
the cylinder at the end of the stroke 210 cub. ft., the principal results were:

With daylight oil the explosion pressure was 153-4 lb per square 
inch above atmosphere, and with Russian oil 134-3 lb. The terminal 
pressure at the moment of opening the exhaust valve with daylight 
oil was 35-4 lb and with Russian oil 33-7 per square inch. The compression pressure with daylight oil was 53 lb, and with Russian oil 270 lb pressure above atmosphere. Professor Unwin calculated the 
amount of heat accounted for by the indicator as 18.8\% in the 
case of daylight oil and 15.2\% in the case of Russian oil.

The Hornsby-Ackroyd engine is an example of the class in which 
the oil is injected into the cylinder and there vaporized. Fig. 12

![Fig. 12.—Hornsby-Ackroyd Engine (section through engine, vaporizer and cylinder).](image)

is a section through the vaporizer and cylinder of this engine, and 
fig. 13 shows the inlet and exhaust valves also in section placed in 
front of the vaporizer and cylinder section. Vaporizing is conducted 
in the interior of the combustion chamber, which is so arranged that 
the air entering at the engine is heated to a temperature sufficiently 
high to enable the oil to be vaporized by mere injection upon the hot 
surfaces. The vaporizer A is heated up by a separate lamp, the oil 
is injected at the oil inlet B, and the engine takes the air from 
the exhaust valve C. The sides of the chamber are sufficiently 
hot to cause explosion, under the pressure of which the piston 
moves forward. As the vaporizer A is not water-jacketed, and is 
connected to the metal of the back cover only by the small section 
or area of cast-iron forming the metal neck o, the heat given to the

![Fig. 13.—Hornsby - Ackroyd Engine (section through valves, vaporizer and cylinder).](image)

surface by each explosion is sufficient to keep its temperature at 
about 700-800\(^o\) C. Oil vapour mixed with air will explode by 
contact with a metal surface at a comparatively low temperature; 
this accounts for the explosion of the compressed mixture in the 
combustion chamber A, by per hour. It has long been known that under certain conditions of internal 
surface a gas engine may be made to run with very great regularity, 
without incandescent tube or any other form of igniter, if some 
portion of the internal surfaces of the cylinder or combustion space 
be so arranged that the temperature may be too low to ignite the mixture at 
ambient temperature, yet when compression is completed the 
mixture will often ignite in a perfectly regular manner. It is a curious 
fact that with heavy oils ignition is per minute for the exhaust valve D, and an explosion is 
accounted for by the indicator as 18.8\% in the case of daylight oil and 15.2\% in the case of Russian oil.

The Hornsby-Ackroyd engine is an example of the class in which 
the oil is injected into the cylinder and there vaporized. Fig. 12

OILLETS—OILS

Fig. 15.—Crossey Oil Engine.

loads. The principal difference between this engine and the Hornsby engine already described lies in the use of the separate ignition tube H and in the water sprayer F, which acts as a snuffing valve, taking in a little air and water when the engine becomes hot. Messrs. Crossey inform the writer that the consumption of either crude or refined oil is about 63 of a pint per horse-power on full load. They also give a test of a small engine developing 7 B.H.P., which consumed 601 pint per B.H.P. per hour of Rock Light refined lamp oil and only 603 pint per B.H.P. per hour of crude Borneo petroleum oil.

Engines in which the oil is vaporized in a device external to the cylinder have almost disappeared, because of the great success of the Hornsby-Ackroyd type, where oil is injected into, and vaporized within, the cylinder. It has been found, however, that many petrol engines having jet carburettors will operate with the heavier oil if the jet carburettor is suitably heated by means of the exhaust gases. In some engines it is customary to start with petrol, and then when the parts have become sufficiently heated to substitute paraffin or heavy petroleum oil, putting the heavy oil through the same spraying process as the petrol and evaporating the spray by hot walls before entering the cylinder.

Mr. Diesel has produced a very interesting engine which departs considerably from other types. In it air alone is drawn into the cylinder on the charging stroke; the air is compressed on the return stroke to a very high pressure generally to over 400 lb. per sq. in. This compression raises the air to incandescence, and then heavy oil is injected into the incandescent air by a small portion of air compressed to a still higher point. The oil ignites at once as it enters the combustion space, and so a power impulse is obtained, but without explosion. The pressure does not rise above the pressure of air and oil injection. The Diesel engine thus embodies two very original features; it operates at compression pressures very much higher than those used in any other internal combustion engines, and it dispenses with the usual igniting devices by rendering the air incandescent, and the engine operates generally on the Otto cycle, but it is also built as an impulse engine at every revolution. Mr. Diesel has shown great determination and perseverance, and the engine has now attained a position of considerable commercial importance. It is made on the continent, in England and in America, in sizes up to 1000 H.P., and it has been applied to many purposes on land and also to the propulsion of small vessels. The engine gives a very high thermal efficiency. The present writer has calculated the following values from a test of a 300 B.H.P. Diesel oil engine made by Mr. Michael Longridge, M.Inst.C.E. The engine had three cylinders, each of 22-05 in. diameter and stroke 29-52 in., each cylinder operating on the Otto cycle. The main results were as follows:—

(D. C.)

OILLETS—OILS—OILS

(from an O. Fr. diminutive of oil, eye, in Mod. Fr. oillet; other English variants are oylets, eyelets, or eyelet-holes), the architectural term given to the arrow slits in the walls of medieval fortifications, but more strictly applied to the round hole or circle with which the openings terminate. The same term is applied to the small circles inscribed in the tracery-head of the windows of the Decorated and Perpendicular periods, sometimes varied with trefoils and quatrefoils.

OILS (adopted from the Fr. huile, mod. huile, Lat. oleum, olive oil), the generic expression for substances belonging to extensive series of bodies of diverse chemical character, all of which have the common physical property of being fluid either at the ordinary temperature or at temperatures below the boiling-point of water. Formerly, when substances were principally classified by obvious characteristics, the word included such a body as "oil of vitriol" (sulphuric acid), which has of course nothing in common with what is now understood under the term oils. In its most comprehensive ordinary acceptation the word embraces at present the fluid fixed oils or fatty oils (e.g. olive oil), the soft fats which may be fluid in their country of origin (e.g. coco-nut oil, palm oil), the hard fats (e.g. tallow), the still harder vegetable and animal waxes (e.g. carnauba wax, beeswax), the odoriferous ethereal (essential) oils, and the fluid and solid volatile hydrocarbons—mineral hydrocarbons—found in nature or obtained from natural products by destructive distillation.

The common characteristic of all these substances is that they consist principally, in some cases exclusively, of carbon and hydrogen. They are all readily inflammable and are practically insoluble in water. The mineral hydrocarbons found in nature or obtained by destructive distillation do not come within the range of this article (see NAPHTHA, PARAFFIN, PETROLEUM), which is restricted to the following two large groups of bodies, formed naturally within the vegetable and animal organisms, viz. (1) Fixed oils, fats and waxes, and (2) Essential, ethereal or volatile oils.

The substances to be considered under this head divide themselves naturally into two large classes, viz. fatty (fixed) oils and fats on the one hand, and waxes on the other, the distinction between the two classes being based on a most important chemical difference. The fixed oils and fats consist essentially of glycerides, i.e. esters formed by the union of three molecules of fatty acids with one molecule of the trihydric alcohol glycerol (glyceric acid), whereas the waxes consist of esters formed by the union of one molecule of fatty acid with one molecule of a monobasic alcohol, such as cetyl alcohol, cholesterol, &c. Only in the case of the wax so called two molecules of fatty acids are combined with one molecule of a dihydric (bivalent) alcohol. It must be pointed out that in common parlance this distinction does not find its ready expression. Thus Japon wax is a glyceride and should be more correctly termed Japan tallow, whereas sperm oil is, chemically speaking, a wax. Although these two classes of substances have a number of physical properties in common, they must be considered under separate heads. The true chemical constitution of oils and fats was first expounded by the classical researches of Chevreul, embodied in his work, Recherches sur les corps gras d'origine animale (1823; reprinted 1850).

(a) Fatty (fixed) Oils and Fats.—The fatty (fixed) oils and fats form a well-defined and homogeneous group of substances, passing through all gradations of consistency, from oils which are fluid even below the freezing-point of water, up to the hardest fats which melt at about 50° C. Therefore, no sharp distinction can be made between fatty oils and fats. Nevertheless, it is convenient to apply the term "oil" to those glycerides which are fluid below about 20° C, and the term "fat" to those which are solid above this temperature.

Chemical Composition.—No oil or fat is found in nature consisting of a single chemical individual, i.e. a fat consisting of the glyceride of one fatty acid only, such as stearin or tristearin, C17H35-C17H35-C17H35-O(CH2)2-OH, the glycinen ester of stearic acid, C17H35-C17H35-C17H35-CO2H. The natural oils and fats are mixtures of at least two or three different triglycerides, the most important of which are tristearin, tripalmitin, C17H35-O-C17H35-O-C17H35 (with a very small amount of mixture with the stearic-palmitic acid, C17H35-O-C17H35-C17H35-O-C17H35), trilinolein, C17H35-O-C17H35-O-C17H35. These three glycerides have been usually considered the chief
OILS

The constituents of most oils and fats, but latterly there have been recognized as widely distributed trilinolein, the glyceride of linolic acid, and triethenolenin, the glyceride of linolenic acid. The two last-named glycerides are characteristic of the semi-drying and drying oils respectively. In addition to the fatty acids mentioned already there occur also, although in much smaller quantities, other fatty acids combined with glycerin, as natural glycerides, such as the glyceride of butyric acid in butter-fat, of caprico, caprylic and capric acids in butter-fat and in coco-nut oil, lauric acid in coco-nut and palm-nut oils, and myristic acid in mace butter. These glycerides are, therefore, characteristic of the oils and fats named.

In the classified list below the most important fatty acids occurring in oils and fats are enumerated (cf. Waxes, below).

Up to the recently the oils and fats were looked upon as consisting in the main of a mixture of triglycerides, in which the three combined fatty acids are identical, as is the case in the above-named glycerides. Such glycerides are termed "simple glycerides." Recently, however, glycerides have been found in which the glycerin is combined with two and even three different acid radicals; examples of such glycerides are distearo-olein, C₂₀H₃₂(O-C₈H₁₇O₂)₂, (O-C₂₀H₄₂O₂), and stearo-palmito-olein, C₁₂H₂₄(O-C₂₀H₄₂O₂) (O-C₂₀H₄₂O₂) (O-C₁₂H₂₄O₂); such glycerides are termed "mixed glycerides." The glycerides occurring in natural oils and fats differ, therefore, in the first instance by the different fatty acids contained in them, and secondly, even if they do contain the same fatty acids, by different proportions of the several simple and mixed glycerides.

Since the methods of preparing the vegetable and animal fats are comparatively crude ones, they usually contain certain impurities of one kind or another, such as colouring and mucilaginous matter, remnants of vegetable and animal tissues, &c. For the most part these foreign substances can be removed by processes of refining, but even after this purification they still retain small quantities of foreign substances, such as traces of colouring matters, albuminoid and (or) resinous substances, and other foreign substances, which remain dissolved in the oils and fats, and can only be isolated after saponification of the fat. These foreign substances are comprised in the term "unsaponifiable matter." The most important constituents of the "unsaponifiable matter" are phytosterol C₃₆H₇₀O₂ or C₃₆H₇₀O₂, and the isomeric cholesterol. The former occurs in all oils and fats of vegetable
origin; the latter is characteristic of all oils and fats of animal origin. This important difference furnishes a method of distinguishing by chemical means vegetable oils and fats from animal oils and fats. This distinction will be made use of in the classification of the oils and fats. A second guiding principle is afforded by the different amounts of iodine (see Oil Testing below) the various oils and fats are capable of absorbing. Since this capacity runs parallel with one of the best-known properties of oils and fats, viz. the power of absorbing larger or smaller quantities of oxygen on exposure to the air, we arrive at the following classification:

I. FATTY OILS OR LIQUID FATS
A. Vegetable oils.
1. Drying oils.
2. Semi-drying oils.
B. Animal oils.

2. Terrestrial animal oils.

II. SOLID FATS
A. Vegetable fats.
1. Drying fats.
2. Semi-drying fats.
B. Animal fats.

Physical Properties.—The specific gravities of oils and fats vary between the limits of 0.910 and 0.925, whereas the drying oils have specific gravities of about 0.930. The so-called castor oil, which has been somewhat higher specific gravities, up to 0.930. The high specific gravity, 0.970, is owned by castor oil and cacao butter, and the highest specific gravity observed hitherto, 0.975, by Japan wax and myrtle wax. In their liquid state and fats easily penetrate into the pores of dry substances; on paper they leave a translucent spot—"grease spot"—which cannot be removed by washing with water and subsequent drying. A curious fact, which may be of use for the detection of the miniest quanta of oils and fats may be noticed when the pan or crucible is heated in layers of paper without having been touched with the fingers rotates when thrown on clean water, the rotation ceasing immediately when a trace of oil or fat is added such as introduced by touching the water with a needle which has been passed previously through the hair. The oils and fats are practically insoluble in water. With the exception of castor oil they are insoluble in cold alcohol; in boiling alcohol somewhat larger quantities dissolve. They are completely soluble in ether, carbon bisulphide, chloroform, carbon tetrachloride, petroleum ether, and benzene. Oils and fats have no distinct melting or solidifying point. This is not only due to the fact that they are mixtures of several glycerides, but also that even pure glycerides, such as glycerol, on melting form two mUltiliglycerides, a so-called “double melting-point,” the triglycerides melting at a certain temperature, then solidifying at a higher temperature to melt again on further heating. This curious behaviour was looked upon by Dufy as being due to the existence of two isomeric modifications, the actual occurrence of which has been proved (1907) in the case of several mixed glycerides. The freezing points of those oils which are fluid at the ordinary temperature range from a few degrees above zero down to —28° (limnet oil). At low temperatures solid portions—usually termed “stearine” —separate out from many oils; in the case of cotton-seed oil the separation takes place at 12° C. These solid portions can be filtered off, and thus are obtained the commercial “demargarinated oils” or “winter oils”.

Oils and fats can be heated to a temperature of 200° to 250° C. without undergoing any material change, provided prolonged contact with air is avoided. On being heated above 250° up to 300° some oils, like linseed oil, safflower oil, unripened oil (Chinese or Japanese wood oil) and even castor oil, undergo a change which is most likely due to polymerization. In the case of castor oil solid products are formed. Above 300° C. all oils and fats are decomposed; this is evidenced by evolution of acrolein, which possesses the well-known pungent odour of burning fat. At the same time hydrocarbons are formed (see Petroleum).

On exposure to the atmosphere, oils and fats gradually undergo certain changes. The drying oils absorb oxygen somewhat rapidly and dry to a film or skin, especially if exposed in a thin layer. Extensive use of this property is made in the paint and varnish trades. The semi-drying oils absorb oxygen more slowly than the drying oils, and are, therefore, useless as paint oils. Still, in course of time, they absorb oxygen distinctly enough to become thickened. The property of the semi-drying oils to absorb oxygen is accelerated by spreading such oils over a large surface, notably over woolen or cotton fibres, when absorption proceeds so rapidly that frequently spontaneous combustion will ensue. Many fires in the ancient oil mills have been caused thereby. The non-drying oils, the type of which is olive oil, do not become oxidized readily on exposure to the air, although gradually a change takes place, the oils thickening slightly and acquiring that peculiar disagreeable smell and acid taste, which are defined by the term “rancid.” The changes conditioning rancidity, although not yet fully understood in all details, must be ascribed in the first instance to slow hydrolysis (“saponification”) of the oils and fats by the moisture of the air, especially if favoured by insolation, when water is taken up by the oils and fats, and free fatty acids are formed. The fatty acids so set free are then more readily attacked by the oxygen of the air, and oxygenated products are formed, which impart to the oils and fats the rancid smell and taste. The products of oxidation are not yet fully known; most likely they consist of lower fatty acids, such as formic and acetic acids, and perhaps also of aldehydes and ketones. If the fats and oils are well protected from air and light, they can be kept indefinitely. In fact C. Friedel has found unchanged triglycerides in the stone niches that had been stored several thousand years in caves in the tombs of a Bossu. If the air is dry and moisture is allowed free play, the hydrolysis of the oils and fats may become so complete that only the insoluble fatty acids remain behind, the glycerin being washed away. This is exemplified by adipocere, and also by Irish bog butter, which consists chiefly of free fatty acids.

The property of oils and fats of being readily hydrolysed is a most important one, and very extensive use of it is made in the arts (soap-making, candle-making and recovery of their by-products). If oils and fats are treated with water alone under high pressure (corresponding to a temperature of about 220° C.), or in the presence of water with caustic alkalis or alkaline earths or basic metallic oxides (which bodies act as “catalysers”) at lower pressures, they are converted in the first instance into free fatty acids and glycerin. If an amount of the bases sufficient to combine subsequently with the fatty acids be present, then the corresponding salts of these fatty acids are formed, such as sodium salts of fatty acids (hard soap) or potassium salts of the fatty acids (soft soap), soaps of the alkaline earth (lime soap), or soaps of the metallic oxides (zinc soap, &c.). The conversion of the glycerides (triglycerides) into fatty acids and glycerin must be looked upon as a reaction which takes place in stages, one molecule of a triglyceride being converted first into diglycerides, then into monoglycerides, and the last molecule being changed into monoglyceride, and a second molecule of fatty acid, and finally the monoglyceride being converted into one molecule of fatty acid and glycerin. All these reactions take place concurrently, so that one molecule of oil or fat may still retain its ephemeral existence, whilst another molecule is already broken up completely into free fatty acids and glycerin.

The oils and fats used in the industries are not drawn from any very great number of sources. The tables on the following pages contain chiefly the most important oils and fats together with their sources, yields and principal uses, arranged according to the above classification, and according to the magnitude of the iodine value. It should be added that many other oils and fats are only waiting improved conditions of transport to enter into successful competition with some of those that are already on the market.

Extraction.—Since the oils and fats have always served the human race as one of the most important articles of food, the oil and fat industry may well be considered to be as old as the human race itself. The methods of preparing oils and fats range themselves under three heads: (1) Extraction of oil by “rendering,” i.e. boiling out with water; (2) Extraction of oil by expression; (3) Extraction of oil by means of solvents.

Rendering.—The crudest method of rendering oils from seeds, still practised in Central India and on some of the South Sea Islands, consists in heating the oil with a heavy stone, which allows them to melt by the heat of the sun, when the exuding oil runs off and is collected. In a somewhat improved form this process of rendering is practised in the preparation of palm oil, and the rendering the best (Cochin) coco-nut oil by boiling the fresh kernels with water. Since hardly any machinery, or only the simplest machinery, is required for these processes, this method has some fascination for
inventors, and even at the present day processes are being patented, having for their object the boiling out of fruits with water or salt solutions, so as to facilitate the separation of the oil from the pulp by gravitation. Naturally these processes can only be applied to those seeds which contain large quantities of fatty matter, such as con-nuts and olives. The rendering process is, however, applied on a very large scale to the production of animal oils and fats. Formerly the animal oils and fats were obtained by heating the tissues con-taining the oils or fats over a free fire, when the cell membranes burst and the liquid fat flowed out. The cave-dweller who first collected the fat dripping off the deer on the roasting spit may well be looked upon as the first manufacturer of tallow. This crude process is now classed amongst the noxious trades, owing to the offensive stench given off, and must be considered as almost extinct in this country. Even on whaling vessels, where up to recently whale oil, seal oil and sperm oil (see Waxes, below) were obtained exclusively by "trying," i.e. by melting the blubber over a free fire, the process of rendering is fast becoming obsolete, the modern practice being to deliver the blubber in as fresh a state as possible to the "whaling establishments," where the oil is rendered by methods closely resembling those worked in the enormous rendering establishments (for tallow, lard, bone fat) in the United States and in South America. The method consists essentially in cutting up the fatty matter into small fragments, which are transferred into vessels containing water, wherein the comminuted mass is heated by steam, either under ordinary pressure in open vessels or under higher pressure in digestors. The fat gradually exudes and collects on the top of the water, whilst the membranous matter, "greaves," falls to the bottom. The fat is then drawn off the aqueous (gluey) layer, and strained through sieves or filters. The greaves are placed

in hair or woollen bags and submitted to hydraulic pressure, by which a further portion of oil or fat is obtained (cf. Pressing, below). In the case of those animal fats which are intended for edible purposes, such as lard, suet for margarine, the greatest cleanliness must, of course, be observed, and the temperature must be kept as low as possible, in order to obtain a perfectly sweet and pure material. Pressing.—The boiling out process cannot be applied to small seeds, such as linseed and rape seed. Whilst the original method of obtaining seed oils may perhaps have been the same which is still used in India, viz. triturating of (rags, which the seeds can exude, it may be safely assumed that the process of expressing has been applied in the first instance to the preparation of olive oil. The first woman who expressed olives packed in a sack by beating stones on them may be considered as the inventor of all the processes that subsequently came into use. Pliny describes in detail the apparatus and processes for obtaining olive oil in vase among his Roman contemporaries, who used already a simple screw press, a knowledge of which they had derived from the Greeks. In the East, where vegetable oils form an important article of food and serve also for other domestic purposes, various ingenious applications of lever presses and wedge presses, and even of combined lever and wedge presses, have been used from the remotest time. At an early stage of history the Chinese employed the same series of operations which are followed in the most advanced oil mills of modern time, viz. bruising and reducing the seeds to meal under an edge-stone, heating the meal in an open pan, and pressing out the oil in a press in which the wedges were driven by hammers. This primitive process is still being carried out in Manchuria, in the production of soja bean cake and soja bean oil, one of the staple industries of that country. The olive press, which was also used in the West for expressing the grape juice, found its way from the south of France to the north, and was employed there for expressing poppy seed and rape seed. The apparatus was then gradually improved, and thus evolved the modern forms of the screw press, next the Dutch or stands, which finally became the hydraulic press. With the screw press, even in its most improved form, the amount of pressure practically obtainable is limited from the failure of its parts under the severe inelastic strain. Hence this kind of press has found only limited application, as in the industry of olive oil for expressing the best and finest virgin oil, and in the production of animal fats for edible purposes, such as lard and oleomargarine. The Dutch or plaster press, invented in Holland in the 17th century, was up to the early years of the 19th century almost exclusively employed in Europe for pressing oil-seeds. It consists of two principal parts, an oblong rectangular box with an arrangement of plates, blocks and wedges, and over it a framework with heavy stampers which produce the pressure by their fall. The press box first consisted of strongly bound oaken planks, but later cast-iron boxes were introduced. At each extremity of the box a bag of oil-meal was placed between two perforated iron plates, next to which were inserted filling-up pieces of wood, two of which were oblique, so that the wedges which exercised the pressure could be readily driven home. This press has had to yield place to the hydraulic press, although in some old-fashioned establishments in Holland the stamper press could still be seen at work in the 'eighties of the 19th century. The invention of the hydraulic press in 1795 by Joseph Mocaya (Eng. Patent 30th April 1795) effected the greatest revolution in the oil industry, bringing a new, easily controlled and almost unlimited source of power into play; the limit of the power being solely reached by the limit of the strength of the material which the engine is able to produce. Since then the hydraulic press has practically completely superseded all other appliances used for expression, and in consequence of this epoch-making invention, assisted as it was later on by the accumulator—invented by William George (later Lord) Armstrong in 1843—the seed-crushing industry reached a perfection of mechanical detail which soon secured its supremacy for England. The sequence of operations in treating oil seeds, oil nuts, &c., for the separation of their contained oils is at the present time as follows: The preliminary operations are the separation of the oil seeds and nuts are freed from dust, sand and other impurities by stirring in an inclined revolving cylinder or sieving machine, covered with woven wire, having meshes varying according to the size and nature of the seed operated upon. This preliminary purification is of the greatest importance, especially for the preparation of edible oils and fats. In the case of those seeds amongst which are found pieces of iron (hammer heads amongst palm kernels, &c.), the seeds are passed over magnets, or screens which separate the pieces of iron. The seeds and nuts are then decorticated (where required), the shells removed, and the kernels ("meats") converted into a pulp mass or meal (in older establishments by crushing and grinding between stones in edge-runners) on passing through a hopper over rollers consisting of five chilled iron or steel cylinders mounted vertically like the bowls of a calendar. These rollers are finely grooved so that the seed is cut up whilst passing in succession between the first and second rollers in the series, then between the second and the third, and so
on to the last, when the grains are sufficiently bruised, crushed and ground. The distance between the rollers can be easily regulated so that the seed leaving the bottom roller has the desired fineness. The comminuted mass, forming a more or less coarse meal, is either extracted with solvents, or subjected to hydraulic pressing, according to the quality of the product to be manufactured. For the preparation of edible oils and fats the meal is expressed in the cold, after having been packed into bags and placed in hydraulic presses under weight, and the resulting meal is kept for a number of weeks, and the cakes are allowed to remain under pressure for about seven minutes.

The oil exuding in the cold dissolves the smallest amount of colouring matter, &c., and hence has suffered least in its quality. Oils so obtained are termed "cold drawn oils," "cold pressed oils," "pressed oils," "salad oils," "virgin oils." By pressing in the cold, obviously only part of the oil or fat is recovered. A further quantity is obtained by expressing the seed meal at a somewhat elevated temperature, reached by warming the press with steam, and it is thereby possible to effect the cold pressing of substances which are not recovered in the first pressing. The second stage of the process is called "second pressing" and of the "third pressing" are obtained.

In the case of oleaginous seeds of low value (cotton-seed, linseed) it is of importance to express in one operation the largest possible quantity of oil. In the case of the beechnut the bruised seed is pressed between the five-roller mill, generally warmed at once in a steam-jacketed kettle fitted with a mixing gear, by passing steam into the jacket, and sending at the same time some steam through a rose, fixed in the ketle, heated and then sent into the lower part of the machine. The survival of the older method of moistening the seed with a little water, while the seeds were bruised under edge-runners, so as to lower the temperature and facilitate the bursting of the cells. The warmer may be termed the "hydraulic," i.e., in the process the oil is pressed under heat, and the "cold," i.e., the oil is expressed without heat, or, more correctly, "cold" to the extent that the seed and oil are kept below the temperature of the boiling water. The "cold" process results in a better oil than the "hot", and the latter may be further improved by the "second pressing." The "hot" process gives a better oil, but the "cold" is preferable for the large quantities of the so-called vegetable oil which are obtained by the process described above.

Extraction by Solvents.—The cakes obtained in the foregoing process still retain considerable proportions of oil, not less than 4%, and are therefore usually extracted with solvents. By this process the oil is recovered in larger quantities than are yielded by the above-described methods, processes having for their object the extraction of the seeds by volatile solvents must be resorted to. Extraction by means of carbon bisulphide was for some years the only process employed by the chemical industry for the extraction of vegetable oils. This process, however, has been largely supplanted by the extraction of the oil from the presscakes with the use of volatile hydrocarbons, such as benzene, toluene, and carbon bisulphide.

The apparatus employed for large-scale operations compacts a flat sheet of the press-cakes, and the solvent is allowed to percolate through the cake. The solvent extracts the oil from the press-cake, and, being heavier than water, collects in the lower part of the apparatus, the cakes remaining at the top. To ensure that the solvent shall float, the press-cakes are generally composed of a number of layers of cakes, the solvent being poured between the layers. The solvent is usually benzene, toluene, or carbon bisulphide.

The solvent is removed by steaming the press-cakes, and the cake is ready for further pressing or refining. The cake, after being pressed, is cleaned by passing steam through it, so as to expel the solvent and dried. The cake is then usually packed in bags, and the oil extracted is drawn off as required.
is driven off and recovered by condensing the vapours in a cooling coil, to be used again. The last remnant of volatile solvents in the oil is driven off by a current of open steam blown through the oil in the warm state. The extracting process in the hot is carried out in apparatus, the principle of which is exemplified by the well-known Soxhlet extractor. The condensed solvent is placed inside a vessel connected with an upright refrigerator on trays or baskets, and is surrounded there by the volatile solvent. On heating the solvent with steam through a coil or jacket, the vapours rise through and around the vessel and pass into the refrigerator, where they are condensed and fall back as a condensed liquid through the meal, percolating it as they pass downward, and reaching to the bottom of the vessel as a more or less saturated solution of oil in the solvent. The solvent is then evaporated, leaving the oil at the bottom of the vessel until the extraction is deemed finished. The solution of fat is then run off into a still, as described already, and the last traces of solvent are driven out. The solvent is recovered and used again.

With regard to olive, linseed and dehydrators of the last two mentioned processes—expression and extraction—the adoption of either will largely depend on local conditions and the objects for which the products are intended. Wherever the cake is the main product, expression will command itself as the most advantageous process. Where, however, the fatty material forms the main product, as in the case of palm kernel oil, or sesame and coco-nut oils from damaged seeds (which would no longer yield proper cattle food), the process of extraction will be preferred, especially when the price of oils is high. In some localities the prices of producing oil in this way will be found by themselves, as in the case of the production of olive oil. The fruits are expressed, and after the edible qualities and best class of oils for technical purposes have been taken off by expression, the remaining pulp is extracted by means of solvents. This process is known under the name of mixed process (houiller mixte).

Refining and Bleaching.—The oils and fats prepared by any of the methods detailed above are in their fresh state, and, if got from perfectly fresh (“sweet”) material, practically neutral. If care be exercised in the process of rendering animal oils and fats or expressing oils in the cold, the products are, as a rule, sufficiently pure to be delivered to the consumer, after a preliminary settling has allowed any mucilaginous matter, such as animal or vegetable fibres or other impurities, and also traces of moisture, to separate out. This spontaneous clarification was at one time the only method in vogue. This process is now shortened by filtering oils through cotton or other materials, brightening them, e.g. by blowing with air. In many cases these methods still suffice for the production of commercial oils and fats.

In special cases, such as the preparation of edible oils and fats, a further improvement in colour and greater purity is obtained by filtering the oils over charcoal, or over natural absorbent earths, such as fuller’s earth. Where this process does not suffice, as in the case of coco-nut oil or palm kernel oil, a preliminary purification in a current of steam must be resorted to before the final purification, described above, is carried out. Oils intended for use on the table which deposit “stearine” in winter must be freed from such solid fats. This is done by allowing the oil to cool down to a low temperature and pressing it through cloths in a press, when a lipid oil exudes, which remains proof against cold—“winter oil.” Most olive oils are naturally non-congealing oils, whereas the Tunisian and Algerian olive oils deposit so much “stearine” that they must be “demargarinated.” Similar methods are employed in the production of lard oil, edible cotton-seed oil, &c. For refining oils and fats intended for edible purposes only the foregoing methods, which may be summarized under the name physical methods, can be used. The only chemical permissible are alkalis or alkaline earths to remove free fatty acids present. Treatment with other chemicals renders the oils and fats unfit for consumption. Therefore all bleaching and refining processes involving other means than those enumerated can only be used for technical oils and fats, such as lubricating oils, burning oils, paint oils, soap-making oils, &c.

Bleaching by the aid of chemicals requires great circumspection. There is no universal method of oil-refining applicable to any and every oil or fat. Not only must each kind of oil or fat be considered as a special problem, but frequently even varieties of one and the same oil or fat are apt to cause the same difficulties as would a new individual. In many cases the purification by means of sulphuric acid, invented and patented by Charles Gower in 1792 (frequently ascribed to Thénard), is still usefully applied. It consists in treating the oil with a small percentage of a more or less concentrated sulphuric acid, according to the nature of the oil or fat. The acid not only takes up water, but it acts on the suspended impurities, carbonizing them to some extent, and thus causing them to coagulate and fall down in the form of a flocculent mass, which carries with it mechanically other impurities which have not been acted upon. This method is chiefly used in the refining of linseed and rape oils. Purification by means of strong caustic soda was first recommended as a general process by Louis C. Arthur Barreswil, his suggestion being to heat the oil and add 2% to 3% of caustic soda. In most cases the purification consisted in removing the free fatty acids from rancid oils and fats, the caustic soda forming a soap with the fatty acids, which would either rise as a scum and lift up with it impurities, or fall to the bottom and carry down impurities. This process is a useful one in the case of cotton-seed oil. As a rule, however, it is a very precarious one, since emulsions are formed which prevent in many cases the separation of oil altogether. After the treatment with sulphuric acid or caustic soda, the oils must be washed to remove the last traces of chemicals. The water is then allowed to settle out, and the oils are finally filtered. The products of chemical which have been proposed from time to time for the purification of oils and fats are legion, and so long as the nature of oils and fats was little understood, a secret trade in oil-purifying chemicals flourished. With our present knowledge most of these chemicals may be removed into the limbo of useless things. The general methods of bleaching besides those mentioned already as physical methods, viz. filtration over charcoal or bleaching earth, are chiefly methods based on bleaching by means of oxygen or by chlorine. The methods of bleaching by oxygen include all those which aim at the bleaching by exposure to the air and to sunlight (as in the case of artists’ linseed-oil), or where oxygen or ozone is introduced in the form of gas or is evolved by chemicals, as manganese dioxide, potassium bichromate or potassium permanganate and sulphuric acid. In the process of bleaching by means of chlorine either bleaching powder or bichromates and hydrochloric acid are used. It must again be emphasized that no general rule can be laid down as to which process should be employed in each given case. There is still a wide field open for the application of proper processes for the removal of impurities and colouring matters without running the risk of attacking the oil or fat itself.

Oil Testing.—Reliable scientific methods for testing oils and fats date back only to the end of the seventies of the 19th century. Before that time it was believed that not only could individual oils and fats be distinguished from each other by colour reactions, but it was also maintained that falsification could be detected thereby. With one or two exceptions (detection of sesame oil and perhaps also of cotton-seed oil) all colour reactions are identical. The modern methods of oil testing rest chiefly on so-called “quantitative determinations, a number of characteristic ‘values’ being determined which, being based on the special nature of the fatty acids contained in each individual oil or fat, assist in identifying them and also in revealing adulteration. These ‘values’, together with other useful methods, are enumerated in the order of their utility for the purposes of testing.

The saponification value (saponification number) denotes the number of milligrams which one grammme of an oil or fat requires for saponification, or, in other words, for the neutralization of the total fatty acids contained in an oil or fat. We thus measure the alkali absorption value of all fatty acids contained in an oil or fat. The saponification values of most oils and fats lie in the neighbourhood of 195. But the oils belonging to the rape oil group are characterized by considerably lower saponification values, viz. about 175 on account of their containing notable quantities of erucic acid, C16H31O. In the case of those oils which do not belong to the rape oils and yet show abnormally low saponification values, the suspicion is raised at once that a certain amount of mineral oils (which do not absorb
alkali and are therefore termed "unsaponifiable" has been admixed fraudulently. Their amount can be determined in a direct manner by exhausting the saponified mass, after dilution with water, with ether, evaporating the latter and weighing the amount of mineral oil left behind, and by comparing the drying extent of the blended oils, like dolphin jaw and porpoise jaw oils (used for lubricating typewriting machines), with exceedingly high saponification values owing to their containing volatile fatty acids with a small number of carbon atoms. Notable also among the unsaponifiable is castor-oil, which furnishes a nitrogen-containing oil, of which vary from 240 to 260, and especially butter-fat, which has a saponification value of about 227. These high saponification values are due to the presence of (glycerides of) volatile fatty acids, and are of extreme usefulness to the analyst, especially in converting butter-fat for fatty acids and margarine and other fats. These volatile acids are specially measured by the Reischert value (Reischert-Wolffy value). To ascertain this value the volatile acids contained in 5 grammes of an oil or fat are distilled in a minutely prescribed manner, and the distillate-offs (calculated in grams) furnish the iodine value for the unsaturated fatty acids of most of the oils and fats, viz. all those the saponification value of which lies at or below 195, contain practically no volatile acids, i.e. have extremely low Reischert-Wolffy values, all those oils and fats having saponification values and iodine values cannot be amonized and volatile fatty acids. Thus, the Reischert-Metsel value of butter-fat is 25-30, that of coco-nut oil 6-7, and of palm kernel oil about 5-6. This value is indispensable for judging the purity of a butter. One of the most important values of a fat in the commerce is the iodine value. This indicates the percentage of iodine absorbed by an oil or fat when the latter is dissolved in chloroform or carbon tetrachloride, and treated with an accurately measured amount of free iodine supplied in the form of a solution. It is a measure of the per cent. of the unsaturated fatty acids contained in an oil or fat. On this value a scientific classification of all oils and fats can be based, as is shown by the above-given list of oils and fats. The unsaturated fatty acids of all vegetable oils (except those of safflower oil and one or two others) give an iodine value of 90-97; erucic acid, iodine value 75-15; linolic acid, iodine value 181-42; linoleic acid, iodine value 274-1; and elapanodonic acid, iodine value 307-7. Oleic acid occurs in all non-drying oils and fats, and is characteristic of all semi-drying and, to some extent of all drying oils. Linolic acid characterizes all vegetable drying oils; similarly clapanodonic acid characterizes all marine animal oils.

If an individual oil or fat is given, the iodine value alone furnishes the readiest means of finding its place in the above system, and in many cases of identifying it. Even if a mixture of several oils and fats be present, the iodine value assists greatly in the identification of the various components, and furnishes the most important key for the attacking and resolving of this not very simple problem. Thus it points the way to the application of a further method to resolve the isolated fatty acids of an oil or fat into their constituent fatty acids which is important and furnishes the saturated fatty acids, which absorb iodine in various proportions as shown above. This separation is effected by converting the alkali soaps of the fatty acids into lead soaps and treating the latter with ether. A few drops of a few per cent. of the saturated acids, whereas the salts of the above-named unsaturated acids are soluble. The saturated fatty acids can then be further examined, and valuable information is gained by the determination of the melting-points and the composition of the fatty acids. One of the chief characteristics of fatty acids is the iodine value (which is characteristic of ground nut oil) can be identified. In the mixture of unsaturated fatty acids, by means of some more refined methods, clapanodonic acid, oleic acid, and linolic acid and can be amonized. By combining the various methods which have been outlined here, and by the help of some further additional special methods, and by reasoning in a strictly logical manner, it is possible to resolve a mixture of two oils into its fats, and to ascertain more accurately into what compounds the mixture probably consists and determine approximately their quantities. The methods described here do not yet exhaust the armoury of the analytical chemist, but it can only be pointed out in passing that the detection of hydroxylated acids enables the analyst to ascertain the presence of this compound and the isolation of the unsaponifiable matter of oxidized fatty acids enables him to differentiate blown oils from other oils.

Tests such as the Maunon test, the elaidin test and others, which have been practically superseded by the foregoing methods. The viscosity test, although of considerable importance in the examination of lubricating oils, has been shown to have very little discriminative value as a general test.

Commerce.—It may be safely said of the United Kingdom that it takes the foremost position in the world as regards the extent of the oil and fat industries. An estimate made by the writer (Cantor Lectures, "Oils and Fats, their Uses and Applications," Society of Arts, 1904, p. 795), and based on the most reliable information obtainable, led to the conclusion that the fats involved in the oil and fat trade exceeded £1,000,000 per week; in 1907 they approximated £1,250,000 per week. The great centres of the seed-oil trade (linseed, cotton-seed, rapeseed, castor-seed) are Hull, London, Liverpool, Bristol, Leith and Glasgow. Linseed is imported principally from the East Indies, Argentina, Canada, Russia and the United States; cotton-seed is chiefly supplied by Egypt and East India; rape-seed and castor-seed chiefly by East India. The importation of copra and palm kernels for the production of coconut-oil and palm-nut oil is also considerable, but in these two cases Great Britain does not take the first place. Fish and blubber oils are principally produced in Dundee, London and Greenock. The manufacture of cod-liver oil for pharmaceutical purposes is naturally somewhat limited, as Norway, Newfoundland, and latterly also Japan, are more favourably situated as regards the supply of fresh cod, but the technical liver oils (cod oil, shark-liver oil) are produced in very large quantities in Grimsby, Hull, Aberdeen, and latterly also on the west coasts of the United Kingdom. The production of edible fats (marginne, lard compounds, and vegetable butters) has taken root in this country, and bids fair to extend largely. With regard to edible oils, edible cotton-seed oil is the only table oil produced in Great Britain. The United Kingdom is also one of the largest importers of fatty materials.

Practically the whole trade in palm oil, which comes exclusively from West Africa, is confined to Liverpool, and the bulk of the tallow imported into Europe from Australia, South America and the United States, is sold in the markets of London and Liverpool. Lard reaches Great Britain chiefly from the United States. Amongst the edible oils and fats which are largely imported, butter takes the first rank (to an amount of almost £25,000,000 per annum). This food-stuff reaches Great Britain not only from all butter-exporting countries of the continent of Europe, but in increasing quantities also from Australia, Canada, Argentina, Siberia and the United States of America. Next in importance is margarine, the British production of which does not suffice for the consumption, so that large quantities must be imported from Holland, edible olive oil from Italy, the south of France, Spain and the Mediterranean ports generally. Coco-nut oil and copra, both for edible and technical purposes, are largely shipped to Great Britain from the East Indies and Ceylon, Java and the West Indies. Of lesser importance are greases, which form the by-product of the large slaughter-houses in the United States and Argentina, and American (Canadian) and Japanese fish oils.

On the continent of Europe the largest oil-trading centres are on the Mediterranean (Marseilles and Triest), which are geographically more favourably placed than England for the production of such edible oils (in addition to the home-grown olive oil—such as arachis oil, sesame oil and coco-nut oil. Moreover, the native population itself constitutes a large consumer of these oils. In the north of Europe, Hamburg, Rotterdam, Antwerp and Copenhagen are the largest centres of the oil and fat trade. Hamburg and its neighbourhood produces, curiously enough, at present the largest amount of palm-nut oil. The United States takes the foremost place in the world for the production of cottonseed and maize oils, lard, bone fat and fish oils. Canada is likely to outstrip the United States in the trade of fish and blubber oils, and in the near future Japan bids fair to become a very serious competitor in the supply of these oils. Vast stores of hard vegetable fats are still practically wasted in tropical countries, such as India, Indo-China and the Sunda Islands, tropical South America, Africa and China. With the improvement in transport these will no doubt reach European manufacturing centres in larger quantities than has been the case hitherto.

Waxes

The waxes consist chiefly of the fatty acid esters of the higher monohydric alcohols, with which are frequently associated free alcohols as also free fatty acids. In the following two tables the "acids" and "alcohols" hitherto identified in waxes are enumerated in a classified order:—

Spermaceti consists practically of cetyl palmitate, Chinese wax or ceryl palmitate. The other waxes are of more complex composition, especially so wool wax.

The waxes can be classified similarly to the oils and fats as follows:—

I. Liquid waxes.  
II. Solid waxes.  
   A. Vegetable waxes.  
   B. Animal waxes.

The table enumerates the most important waxes:

There are only two liquid waxes known, sperm oil and arctic sperm oil (bottlenose-whale oil), formerly always classed together with the animal oils. In their physical properties the natural waxes simulate the fatty oils and fats. They behave similarly to solvents; and in their liquid condition leave a grease spot on paper. An important property of waxes is that of easily forming emulsions with water, so that large quantities of water can be incorporated with them (lanolin).

The liquid waxes occur in the blubber of the sperm whale, and in the head cavities of those whales which yield spermaceti; this latter is obtained by cooling the crude oil obtained from the head cavities. Vegetable waxes appear to be very widely distributed throughout the vegetable kingdom, and occur mostly as a very thin film covering leaves and also fruits. A few only are found in sufficiently large quantities to be of commercial importance. So far carnaüba wax is practically the only vegetable wax which is of importance in the world's markets. The animal waxes are widely distributed amongst the insects, the most important being beeswax, which is collected in almost all parts of the world. An exceptional position is occupied by wool wax, the main constituent of the natural wool fat which covers the hair of sheep, and is obtained as a by-product in scouring the raw wool. Wool fat is now being purified on a large scale and brought into commerce, under the name of lanolin, as an...
OILS

ointment the beneficient properties of which were known to Dioscorides in the beginning of the present era. Its chemical composition is exceedingly complex, and specially remarkable on account of the considerable proportions of cholesterol and isocholesterol it contains.

Commerce.—The sperm oils are generally sold in the same markets as the fish and blubber oils (see above). For beeswax London is one of the chief marts of the world. In Yorkshire, the centre of the woolen industry, the largest amounts of wool-fat are produced, all attempts to recover the hitherto wasted material in Argentine and Australia having so far not been attended with any marked success. Spermacei is a comparatively unimportant article of commerce; and of Chinese wax small quantities only are imported, as the home manufacture takes up the bulk of the wax for the manufacture of candles, polishes and sizes.

2. Essential or Etherial Oils.

The essential, ethereal, or "volatile" oils constitute a very extensive class of bodies, which possess, in a concentrated form, the odour characteristic of the plants or vegetable substances from which they are obtained. The oils are usually contained in special cells, glands, cavities, or canals within the plants either as such or intermixed with resinous substances; in the latter case the mixtures form oleo-resins, balsams or resins according as the product is soft, solid or hard. A few do not exist ready formed in the plants, but result from the change of inodorous substances; as for instance, bitter almonds and essential oil of mustard.

The essential oils are for the most part insoluble or only very sparingly soluble in water, but in alcohol, ether, fatty oils and mineral oils they dissolve freely. They ignite with great ease, emitting a smoke freely, owing to the large proportion of carbon they contain. Their characteristic odour is often called "volatile," and it is as a rule not oleaginous to the touch and leaves no oily sensation on the spot. They have an aromatic smell and a hot burning taste, and can be distilled unchanged. The crude oils are at the ordinary temperature solid or liquid, some are solid substances, others, again, deposit on standing a crystalline substance. "Hydrocarbons" is the contradistinction to the liquid portion ("c. lacetopon "). The essential oils possess a high refractive power, and most of them rotate the plane of the polarized light. Even so nearly related oils as the oils of turpentine, if obtained from different sources, rotate the plane of the polarized light in opposite directions. In specific gravity the essential oils range from 0·850 to 1·42; the majority are, however, specifically lighter than water. In their chemical constitution the essential oils present a great number of fatty and oil-like substances; they represent a large number of classes of substances of which the most important are: (1) Hydrocarbons, such as pine in oil of turpentine, camphene in citronella oil, limonene in lemon and orange-peel oils, carvone in oil of caraway, etc.; (2) aldehydes, such as trans-cinnamic acid in rose balsam, such as camphor from the camphor tree, and iris which occurs in orris root; (3) phenols, such as eugenol in clove oil, thymol in thyme oil, saffrol in sassafras oil, anethol in anise oil; (4) alcohols and their esters, such as geraniol (Rhodinol) in rose oil and geranium oil, linalool, occurring in bergamot and lavender oils, and as the acetic ester in rose oil, terpineol in cardamom oil, menthol in peppermint oil, eucalyptol in eucalyptus oil and boiled in rosemary oil and Borneo camphor; (5) aldehydes, such as citral and citronellol, the most important of the oleo-resins and oleaginous substances; (6) carboxyls, such as the tartaric acid in sorrel oil; and (7) nitrogenous compounds, such as mustard oil, indol in jasmine oil and antrinathyl ester in neroli and jasmine oils.

Preparation from Plants.—Before essential oils could be prepared synthetically they were obtained from plants by one of the following methods: (1) distillation, (2) expression, (3) extraction, (4) enfleurage, (5) maceration.

The most important of these processes is the first, as it is applicable to a large number of substances of the widest range, such as oil of peppermint, etc. In the process of distillation, it is based on the principle that whilst the odoriferous substances are insoluble in water, the vapour tension is reduced on being treated with steam so that they are carried over by a current of steam. The distillation is generally performed in a still with an inlet for steam and an outlet to carry the vapours laden with essential oils into a condenser. Where water and oil vapours are condensed. On standing, the distillate separates into two layers, an aqueous and an oily layer, the oil floating on or skimming through the water according to its specific gravity. The process of expression is applicable to the obtaining of essential oils which are contained in the rind or skin of the fruits belonging to the citron family, such as orange and lemon oils. The oranges, lemons, &c., are peeled, and the peel is pressed against a large number of fine needles, the exuding oil being absorbed by sponges. It is intended to introduce machinery to replace manual labour. The process of extraction with volatile solvents is similar to that used in the extraction of oils and fats, but as only the most volatile and odorous solvents are used, this process has not yet gained much importance. The process of enfleurage is applicable in those cases where the odoriferous substance is present to a very small extent, and is so tender and liable to deterioration that it cannot be isolated by way of distillation. Thus in the case of neroli oil the petals of orange blossom are largely spread on trays covered with limy earth or hard with fine olive oil. The fatty materials then take up and fix the essential oil. This process is principally employed for preparing pomades and perfumed oils. Less tender plants can be readily identified by a synthetic process, and even in cases where it involves the extracting the odoriferous substances by macerating the flowers in hot oil or molten fat. The essential oil is then dissolved by the fatty substances. The essential oil itself can be recovered from the squashed oils, prepared either by the introduction of a mixture of camphor, or by agitating the perfumed fat in a shaking machine with pure concentrated alcohol. The essential oils pass into the alcoholic solution, which is used as such in perfumery.

Synthetic Preparation.—Since the chemistry of the essential oils has been investigated in a systematic fashion a large number of the chemical individuals mentioned above have been isolated from the oils and identified.

This first step has led to the synthetic production of the most characteristic substances of essential oils in the laboratory, and the synthetic manufacture of essential oils has become one of the most important industries in the world. The production of these languages is a by-product in the manufacture of artificial camphor. This was followed by the production of heliotropin, coumarin and vanilin, and later on by the artificial preparation of Ionone, the most characteristic substance of the violet oils. At present the manufacture of artificial camphor may be considered a solved problem, although it is doubtful whether such camphor will be able to compete in price with the natural product in the future. The aim of the chemist to produce artificial oils, and artificial perfumery, is to compete at present to the more expensive oils. For so long as the great bulk of oils is so cheaply produced in nature's laboratory, the natural products will hold their field for a long time to come.

Applications.—Essential oils have an extensive range of uses, of which the principal are their various applications in perfumery (q.v.). Next to that they play an important part in connexion with food. The value of flavouring herbs, condiments and spices is due in a large measure to the essential oils contained in them. The commercial value of tea, coffee, wine and other beverages may be said to depend largely on the delicate aroma which they owe to the presence of minute quantities of ethereal oils. Hence, essential oils are extensively used for the flavouring of confectionery and other drinks. Nor is their employment less considerable in the manufacture of perfumery and in the preparation of many dietetic articles. Most fruit essences now employed in confectionery are artificially prepared oils, especially is this the case with cheap confectionery (jams, marmalades, &c.) in which the artificial fruit esters to a large extent replace the natural fruity flavour. Thus amy acetate is used as an imitation of the jargonelle-pear flavour; amy valerate replaces apple flavour, and a mixture of ethyl and propyl butyrate yields the so-called pine-apple flavour. Formic ether gives a peach-like odour, and is used for flavouring fictitious rum. Many of the essential oils find extensive use in medicine. In the arts, oil of turpentine is used on the largest scale in the manufacture of varnishes, and in smaller quantities for the production of terpineol and of artificial camphor. Oil of cloves is used in the silverying of mirror glasses. Oils of lavender and of spike are used as vehicles for painting, more especially for the painting of pottery and glass.

The examination of essential oils is by no means an easy task. Each oil requires almost a special method, but with the progress of chemistry the extensive determination that used to be practised with fatty oils has almost disappeared, as the presence of fatty oils is readily detected. Adulteration of expensive oil with cheaper oil is now more extensively practised, and such tests as the determination...

of the saponification value (see above) and of the optical rotation, and in special cases the isolation and quantitative determination of characteristic substances, leads in many very cases to reliable results. The colour, the boiling-point, the specific gravity and solubility of the oils and fats are of importance in this connexion with a view to form an estimate of the genuineness and value of a sample. Quite apart from the genuineness of a sample, its special aroma constitutes the value of an oil, and in this respect the judging of oils may arise from the part, be more readily solved by an experienced perfumer than by the chemist. Thus roses of different origin or even of different years will yield rose oils of widely different value. The cultivation of plants for essential oils has become a large industry, and is especially productive in the south of France (Grasse, Nice, Cannes). The rose oil industry, which had for centuries been located in the valleys of Bulgaria, has now been taken up in Germany (near Leipzig), where roses are actively cultivated for rose oil. China and Japan are also very large producers of essential oils. Owing to the climate other countries are less favoured, although lavender and peppermint are largely cultivated at Mitcham in Surrey, in Hertfordshire and Bedfordshire. Lavender and peppermint oils of English origin rank as the best qualities. As an illustration of the extent to which this part of the industry suffers from the climate, it may be stated that oil from lavender plants grown in England never produces more than 7 to 10% linalool acetate, which gives the characteristic scent to lavender oil, whilst oil from lavender grown in the south of France frequently yields as much as 35% of the ester. The proof that this is due mainly to climatic influences is furnished by the fact that the trans-antarctic and trans-pacific races of lavender, which by year after year approximates more closely in respect of its contents of linalool acetate to the product of the French plant.

For the essential oils, see F. B. Power, Descriptive Catalogue of Essential Oils; L. J. Sawyer, Odorographia (London, 1892 and 1894); E. Gildemeister and F. Hoffmann, Die aetherischen Öle (Berlin, 1899), trans. (1900) by E. Kremers under the title Volatile Oils (Milwaukee, Wisconsin); F. W. Aschan, Chemie der alkylieren Verbindungen (Brunswick, 1905); F. R. Heussler (translated by Pond), The Chemistry of the Terpenes (London, 1904). (J. L.)

OIRON, a village of western France, in the department of Deux-Sèvres, 27 m. E. by S. of Thouars by road. Oiron is celebrated for its château, standing in a park and originally built in the first half of the 16th century by the Gouffier family, rebuilt in the latter half of the 17th century by Francis of Aubusson, duke of La Foulle, and purchased by Madame de Montespan, who passed the latter part of her life. Marshal Villeroi afterwards lived there. The château consists of a main building with two long projecting wings, one of which is a graceful structure of the Renaissance period built over a cloister. The adjoining church, begun in 1518, combines the Gothic and the Renaissance styles and contains the tombs of four members of the Gouffier family. The town, and in other parts of the château and church were mutilated by the Protestants in 1568. The park contains a group of four dolmens.

For the Oiron pottery see CERAMICS.

OISE, a river of northern France, tributary to the Seine, flowing south-west from the Belgian frontier and traversing the departments of Artois, Oise, and Somme. Area basin of basin 3,647 sq. m. Rising in Belgium, it enters in the S.E. of Charny (province of Namur) at a height of 898 ft., the river enters France after a course of little more than 9 m. Flowing through the district of Thiérache, it divides below Guise into several arms and proceeds to the confluen of the Serre, near La Fère (Aisne). Thence as far as the confluence of the Ailette, its course lies through well-wooded country to Compiègne, a short distance above which it receives the Aisne. Skirting the forests of Compiègne, Halatte and Chantilly, all on its left bank, and receiving near Creil the Thérain and the Brêche, the river flows past Pontoise and debouches into the Seine 39 m. below Paris. Its channel is canalized (depth 6 ft. 6 in.) from Janville above Compiègne, to its mouth over a section 60 m. in length. Above Janville a lateral canal continued by the Sambre-Oise canal accompanies the river to Landrecy. It communicates with the canal system of Flanders and with the Somme canal by way of the St Quentin canal (Crozet branch) which unites with it at Chauny. The same town is its point of junction with the Aisne-Oise canal, by which it is linked with the Eastern canal system.

OISE, a department of northern France, three-fourths of which belonged to Lie-de-France and the rest to Picardy, bounded N. by Somme, E. by Aisne, S. by Seine-et-Marne and Seine-Oise, and W. by Eure and Seine-Inférieure. Pop. (1906) 476,049; area 2,272 sq. m. The department is a moderately elevated plateau with pleasant valleys and fine forests, such as those of Compiègne, Ermenonville, Chantilly and Halatte, all in the south-east. It belongs almost entirely to the basin of the Seine—the Somme and the Bresle, which flow into the English Channel, draining but a small area. The most important river is the Oise, which flows through a broad and fertile valley from north-east to south-west, past the towns of Noyon, Compiègne, Pont St Maxence and Creil. On its right it receives the Brêche and the Thérain, and on its left the Aisne, which brings down a larger volume of water than the Oise itself, the Aunette, and the Nonette, which irrigates the valley of Senlis and Chantilly. The Ourcq, a tributary of the Marne, in the south-east, and the Epte, a tributary of the Seine, in the west, also in part belong to the department. These streams are separated by ranges of slight elevation or by isolated hills, the highest being (770 ft.) being in the ridge of Bray, which stretches from Digne to Ermenonville. Creil is the lowest point at the mouth of the Oise, only 66 ft. above sea-level. The climate is very variable, but the range of temperature is moderate.

Clay for bricks and earthenware, sand and building-stone are among the mineral products of Oise, and peat is also worked. Piétrain and Bouonne, have mineral springs. Wheat, oats and other cereals, potatoes and sugar beet are the chief agricultural crops. Cattle are reared more especially in the western districts, where dairying is actively carried on. Bee-keeping is general. Racing stables are numerous in the neighbourhood of Chantilly and Compiègne. Among the industries of the department, manufacture of sugar and alcohol from beetroot occupies a foremost place. The manufacture of furniture, brushes (Beauvais) and other wooden goods and of toys, fancy-ware, buttons, fans and other articles in wood, ivory, bone or mother-of-pearl are widespread industries. There are also woolen and cotton mills, and the making of woolen fabrics, blankets, cloths (Beauvais), hose and lace (Chantilly and its vicinity) is actively carried on. Creil and the neighbouring Montataire form an important metallurgical centre. Oise is served by the Northern railway, on which Creil is an important junction, and its commerce is facilitated by the Oise and its lateral canal and the Aisne, which afford about 70 m. of navigable waterway.

There are four arrondissements—Beauvais, Clermont, Compiègne and Senlis—with 35 cantons and 701 communes. The department forms the diocese of Beauvais (province of Reims) and part of the region of the II. army corps of and of the académie (educational division) of Paris. Its court of appeal is at Amiens. The principal places are Beauvais, the capital, Chantilly, Clermont-en-Beauvaisis, Compiègne, Noyon, Piétrain, Creil and Senlis, who are treated separately. Among the more populous places not mentioned is Méru (55,000), a centre for fancy-ware manufacture. The department abounds in old churches among which, besides those of Beauvais, Noyon and Senlis, may be mentioned those at Morienval (11th and 12th centuries), Maignelay (15th and 16th centuries), Crépy-en-Valois (St Thomas, 12th, 13th and 15th centuries), St Leu d’Esserent (mainly 12th
OJIBWAY—OKAPI

The okapi appears to be intermediate between that of the giraffe on the one hand and that of the extinct Palaeotragus (or Semotherium) of the Lower Pliocene deposits of southern Europe on the other. It has, for instance, a greater development of air-cells in the diaphysis than in the latter, but much less than in the former. Again, in Palaeotragus the horns (present only in the male) are situated immediately over the eye-sockets, in Okapia they are placed just behind the latter, while in Giraffa they are partly on the paretials. In general form, so far as can be judged from the disarticulated skeleton, the okapi was more like an antelope than a giraffe, the fore and hind cannon-bones, and consequently, the entire limbs, being of approximately equal length. From this it seems probable that Palaeotragus and Okapia indicate the ancestral type of the giraffe-line; while it has been further suggested that the apparently hornless Heliadotherium of the

Female Okapi.

Grecian Pliocene may occupy a somewhat similar position in regard to the horned Sivatherium of the Indian Siwaliks.

For these and other allied extinct genera see Pecora; for a full description of the okapi itself the reader should refer to an illustrated memoir by Sir E. Ray Lankester in the Transactions of the Zoological Society of London (xvi. 6, 1902), entitled "On Okapia, a New Genus of Giraffidae from Central Africa."

Little is known with regard to the habits of the okapi. It appears, however, from the observations of Dr J. David, who spent some time in the Albert Edward district, that the creature dwells in the most dense parts of the primeval forest, where there is an undergrowth of solid-leaved, swamp-loving plants, such as arum, Donax and Phrymum, which, with orchids and climbing plants, form a thick and confused mass of vegetation. The leaves of these plants are blackish-green, and in the gloom of the forest, grow more or less horizontally, and are glistening with moisture. The effect of the light falling upon them is to produce along the margin of each a number of short white streaks of light, which contrast most strongly with the shadows cast by the leaves themselves, and with the general twilight gloom of the forest. On the other hand, the thick layer of fallen leaves on the ground, and the bulk of the stems of the forest trees are bluish-brown and russet, thus closely resembling the decaying leaves in an European forest after heavy rain; while the whole effect is precisely similar to that produced by the russet head and body and the striped thighs and limbs of the okapi. The long and mobile muzzle of the okapi appears to be adapted for feeding...
on the low forest underwood and the swamp-vegetation. The small size of the borns of the males is probably also an adaptation to life in thick underwood. In Dr. David's opinion an okapi in its native forest could not be seen at a distance of more than twenty or twenty-five paces. At distances greater than this it is impossible to see anything clearly in these equatorial forests, and it is very difficult to do so even at this short distance. This suggests that the colouring of the okapi is of purely protective type.

By the Arabianized emancipated slaves of the Albert Edward district the okapi is known as the kenge, dô-á-pé being the Pigmies' name for the creature. Dr. David adds that Junker may undoubtedly claim to be the discoverer of the okapi, for, as stated on p. 290 of the third volume of the original German edition of his Travels, he saw in 1878 or 1879 in the Nplo district a portion of the skin with the characteristic black and white stripes. Junker, by whom it was mistaken for a large water-chemovatian or zebra-antelelo, states that to the natives of the Nplo district the okapi is known as the makape. (R. L.*)

OKEHAMPTON, a market town and municipal borough in the Tavistock parliamentary division of Devonshire, England, on the east and west Okement rivers, 22 m. W. by N. of Exeter by the London & South-Western railway. Pop. (1901) 2,560. The church of All Saints has a fine Perpendicular tower, left uninjured when the nave and chancel were burned down in 1842. Glass is made from granaries in which the Meldon Vale falls, 3 m. distant. Below branches of the river abound in small trout. Okehampton Castle, one of the most picturesque ruins in Devon, probably dates from the 15th century, though its keep may be late Norman. It was dismantled under Henry VIII., but considerable portions remain of the chapel, banqueting hall and bower's tower. Immediately opposite are the traces of a supposed British camp, and of the Roman road from Exeter to Cornwall. The custom of tolling the curfew still prevails in Okehampton. The town is governed by a mayor, 4 aldermen and 12 councillors. Area, 503 acres.

Okehampton (Oakmanton) was bestowed by William the Conqueror on Baldwin de Brioninis, and became the caput of the barony of Okehampton. At the time of the Domesday Survey of 1066 it already ranked as a borough, with a castle, a market paying 4 shillings, and four burgesses. In the 18th century the manor passed by marriage to the Courtenays, afterwards earls of Devon, and Robert de Courtenay in 1220 gave the king a falty to hold an annual fair at his manor of Okehampton, on the vigil and feast day of St. Thomas the Apostle. In the reign of Henry III. the inhabitants received a charter (undated) from the earl of Devon, confirming their rights "in woods and in uplands, in ways and in paths, in common of pastures, in waters and in mills. They were to be free from all toll and to elect yearly a portreeve and a beadle." A further grant of privileges was bestowed in 1292 by the earl of Devon, but no charter of incorporation was granted until that from James I. in 1624, and the confirmation of this by Charles II. in 1684 continued to be the governing charter, the corporation consisting of a mayor, seven principal burgesses and eight assistant burgesses, until the Municipal Corporations Act of 1882. On a petition from the inhabitants the town was reincorporated by a new charter in 1885. Okehampton returned two members to parliament in 1300, and again in 1312 and 1313, after which there was an intermission till 1640, from which date two members were returned regularly until the Reform Act of 1832 the borough was disfranchised.

See Victoria County History, Devonshire; W. B. Bridges, History of Okehampton (1889).

OKEN, LORENZ (1779-1851), German naturalist, was born at Bohlsbach, Swabia, on the 1st of August 1779. His real name was Lorenz Ockenfuss, and under that name he was entered at the natural history and medical classes in the university of Wurzburg, whence he proceeded to that of Göttingen, where he became a privat-doect, and abridged his name to Oken. As Lorenz Oken he published in 1802 his small work entitled Grundriss der Naturphilosophie, der Theorie der Sinne, und der darauf gegründeten Classification der Thiere, the first of the series of works which placed him at the head of the "natur-philosophie" or physio-philosophical school of Germany. In it he extended the physical science the philosophical principles which Kant had applied to moral science. Oken had, however, in this application been preceded by J. G. Fichte, who, acknowledging that the materials for a universal science had been discovered by Kant, declared that nothing more was needed than a systematic co-ordination of these materials; and this task Fichte undertook in his famous Doctrine of Science (Wissenschaftslehr), the aim of which was to construct a priori all knowledge. In this attempt, however, Fichte did little more than indicate the path; it was reserved for F. W. J. von Schelling fairly to enter upon it, and for Oken, following him, to explore its mazes yet further, and to produce a systematic plan of the country so surveyed.

In the Grundriss der Naturphilosophie of 1802 Oken sketched the outlines of the scheme he afterwards devoted himself to perfect. The position which he advanced in that remarkable work, and to which he ever after professed adherence, is that "the animal classes are virtually nothing else than a representation of the sense-organs, and that they must be arranged in accordance with them." Agreeably with this idea, Oken contended that there are only five animal classes: (1) the Dermatozoa, or invertebrates; (2) the Classcoza, or Fishes, as being the ones in which the true tongue makes, for the first time, its appearance; (3) the Reptiles, or Serpents, wherein the nose opens for the first time into the mouth and inhaled air; (4) the Ovozoa, or Birds, in which the ear for the first time opens externally; and (5) Ophthalmozoa, or Mammals, in which all the organs of sense are present and complete, the eyes being movable and covered with two lids.

In 1805 Oken made another characteristic advance in the application of the a priori principle, by a book on generation (Die Zeugung), wherein he maintained the proposition that all organic beings originate from and consist of vesicles or cells. These vesicles, when singly detached and regarded in their original process of production, are the infusorial mass or protoplasma (urschleim) whence all larger organisms fashion themselves or are evolved. Their production is therefore nothing else than a regular agglomeration of Infusorior—no, of course, of species already elaborated or perfect, but of mucous vesicles or points in general, which first form themselves by their union or combination into particular species.

One year after the production of this remarkable treatise, Oken advanced another step in the development of his system, and in a volume published in 1806, in which D. G. Kieser (1779-1862) assisted him, entitled Beiträge zur vergleichenden Zoologie, Anatomie, und Physiologie, he demonstrated that the intestines originate from the umbilical vesicle, and that this corresponds to the vitellus or yolk-bag. Caspar Friedrich Wolff had previously proved this fact in the chick (Theoria Generationis, 1774), but he did not see its application as evidence of a general law. Oken showed the importance of the discovery as an illustration of his system. In the same work Oken described and recalled attention to the corpora Wolfisiana, or "primordial kidneys."

The reputation of the young privat-doect of Göttingen had meanwhile reached the ear of Goethe, and in 1807 Oken was invited to fill the office of professor extraordinarius of the medical sciences in the university of Jenae. He accepted the call, and selected for the subject of his inaugural discourse his ideas on the Signification of the Bones of the Skull," based upon a discovery he had made in the previous year. This famous lecture was delivered in the presence of Goethe, as privy-councillor and rector of the university, and was published in the same year, with the title, Uber die Bedeutung der Schädelknochen.

With regard to the origin of the idea, Oken narrates in his Isis that, walking one autumn day in 1806 in the Haar forest, he stumbled upon the blanched skull of a deer, picked up the partially dislocated bones, and contemplated them for a while, when the truth flashed across his mind, and he exclaimed, "It
is a vertebral column!" At a meeting of the German naturalists held at Jena some years afterwards Professor Kieser gave an account of Oken's discovery in the presence of the grand-duke, which account is printed in the tagelbi, or "proceedings," of that meeting. The professor stated that Oken communicated to him his discovery when journeying in 1806 to the island of Wangeroog. On their return to Göttingen Oken explained his ideas by reference to the skull of a turtle in Kieser's collection, which he disarticulated for that purpose with his own hands.

"It is with the greatest pleasure," wrote Kieser, "that I am able to show here the same skull, after having it thirty years in my collection. The single bones of the skull are marked by Oken's own handwriting, which may be so easily known."

The range of Oken's lectures at Jena was a wide one, and they were highly esteemed. They embraced the subjects of natural philosophy, general natural history, zoology, comparative anatomy, the physiology of man, of animals and of plants. The spirit with which he grappled with the vast scope of science is characteristically illustrated in his essay Uber das Universum als Fortsetzung des Sinnessystems, 1808. In this work he lays it down that "organism is none other than a combination of all the universe's activities within a single individual body." This doctrine is the explicit conviction that "the world and organisms alike are products of chance and do not arise from any law or purpose with each other." In the same year he published his Erste Ideen zur Theorie des Leiches, &c., in which he advanced the proposition that "light could be nothing but a polar tension of the ether, evoked by a central body in antagonism with the planets, and heat was nothing other than a motion of this ether"—a sort of vague anticipation of the doctrine of the "correlation of physical forces." In 1809 Oken extended his system to the mineral world, arranging the ores, not according to the metals, but agreeably to their combinations with oxygen, acids and sulphur. In 1810 he summed up his views on organic and inorganic nature into one compendious system. In the first edition of the Lehrbuch der Naturphilosophie, which appeared in that and the following years, he sought to bring his different doctrines into mutual connection, and to "show that the mineral, vegetable and animal kingdoms are not to be arranged arbitrarily in accordance with single and isolated characters, but to be based upon the cardinal organs or anatomical systems, from which a firmly established number of classes would necessarily be evolved; that each class, moreover, takes its starting-point from below, and consequently that the whole of them pass upward until the year 1848."

"As in chemistry, where the combinations follow a definite numerical law, so also in anatomy the organs, in physiology the functions, and in natural history the classes, families, and even genera of minerals, plants, and animals present a similar arithmetical ratio." The Lehrbuch procured for Oken the title of Hofrat, or court-councillor, and in 1812 he was appointed ordinary professor of the natural sciences.

In 1816 he commenced the publication of his well-known periodical, entitled Isis, eine encyclopädische Zeitschrift, vorzüglich für Naturgeschichte, vergleichende Anatomie und Physiologie. In this journal appeared essays and notices not only on the natural sciences but on other subjects of interest; poetry, and even comments on the politics of other German states, were occasionally admitted. This led to representations and remonstrances from the governments criticized or impugned, and the court of Weimar called upon Oken either to suppress the Isis or resign his professorship. He chose the latter alternative. The publication of the Isis at Weimar was prohibited. Oken made arrangements for its issue at Rudolstadt, and this continued intermittently until 1835.

In 1821 Oken promulgated in his Isis the first idea of the annual general meetings of the German naturalists and medical practitioners, which happy idea was realized in the following year, when the first meeting was held at Leipzig. The British Association for the Advancement of Science was at the outset avowedly organized after the German or Okenian model.

In 1828 Oken resumed his original humble duties as privat-docent in the newly-established university of Munich, and soon afterwards he was appointed ordinary professor in the same university. In 1835, on the proposal by the Bavarian government to transfer him to a professorship in a provincial university of the province of the palatine or some other dominions and left the kingdom. He was appointed in 1833 to the professorship of zoology and mineralogy in the then recently-established university of Zurich. There he continued to reside, fulfilling his professional duties and promoting the progress of his favourite sciences, until his death on the 11th of August 1851.

All Oken's writings are eminently deductive illustrations of a foregone and assumed principle, which, with other philosophers of the transcendental school, he deemed equal to the explanation of all the mysteries of nature. According to him, the head was a result of the interaction of the skull, the vertebrae, the limbs and other appendages; this sum of his observations and comparisons—few of which he ever gave in detail—ought always to be borne in mind in comparing the share taken by Oken in homological anatomy with the progress made by other cultivators of that philosophical branch of the science.

The idea of the analogy between the skull, or parts of the skull, and the vertebral column had been previously propounded and ventilated in their lectures by J. H. F. Autenrieth and K. F. Kielmeyer, and in the writings of J. P. Frank. By Oken it was applied chiefly in illustration of the mystical system of Schelling—the "all-in-all" and "all-in-ever-part." From the earliest to the latest of his works Oken's treatise on anatomy is illustrated with the whole trunk with all its systems: the brain is the spinal cord; the abdomen is the vertebral column; the mouth is the intestine and abdomen; the nose is the lungs and thorax; the jaws are the limbs; and the fore-arms and legs are the bones of nails," J. B. von Spix, in his folio Cephalogenese (1818), richly illustrated, could not have missed the facts under the same transcendental guise; and Cuvier ably availed himself of the extravgances of these disciples of Schelling to cast ridicule on the whole inquiry into those higher relations of parts to the grand scheme of the universe.

The vertebral theory of the skull had practically disappeared from anatomical science when the labours of Cuvier drew to their close. In Oken's Archetype and Homologies of the Vertebrate Skeleton (1817) he deduced the unity of the head, and the teleological conclusions, inductively, and the theory rightly stated, as follows: "The head is not a virtual equivalent of the trunk, but is only a portion, i.e., certain modified segments, of the whole body. The jaws are the arches of the first two segments; they are not limbs of the head" (p. 176).

Vaguely and strangely, however, as Oken had blended the idea with his a priori conception of the nature of the head, the chance of appropriating it seems to have overcome the moral sense of the younger generation. Comparative osteology had early attracted Goethe's attention. In 1786 he published at Jena his essay Uber den Zwischenkieferknochens des Menschen und der Thiere, showing that the intermaxillary bone (nasal) of the fish, which gives the remotest hint of his having then possessed the idea of the vertebral analogies of the skull. In 1820, in his Morphologie, he first publicly stated that thirty years before the date of that publication he had discovered the secret relationship between the brae and the bones of the head, and that he had always continued to meditate on this subject. The circumstances under which the poet, in 1820, narrates having become inspired with the original idea, are suspiciously analogous to those described by Oken in 1807, as producing the same effect on his mind. A bleached skull is accidentally discovered in both instances: in Oken's it was that of a deer in the Harz forest; in Goethe's it was that of a sheep picked up in a shoal over whose answer, to and from his house: No hint of any claim of the host is given to the guest; no word of reclamation in any shape appears for some
In Goethe's "Tages- und Jahres-Hefte", he refers to two friends, Reinhard and Voigt, as being cognizant in 1807 of his theory. Why did not one or other of these make known to Oken that he had been so anticipated? I told my friends to keep quiet," writes Goethe in 1825. Spix, in the meantime, in 1813, contributes his share to the development of Oken's ideas in his "Systeme der Wirbeltiere," while Ulrich follows in 1816 with his "Schildkröten-Crâne;" next appears the contribution, in 1818, by L. H. Bojanus, to the vertebral theory of the skull, amplified in the "Paragon" to that anatomist's admirable "Anatomie des Menschen." Following Spix in 1818, Bojanus, visiting some friends at Weimar, there hears the rumour that his friend Oken had been anticipated by the great poet. He communicates it to Oken, who, like an honest man, at once published the statement. The mystery of the whole is thus explained when reflecting on the poet, but restricting himself to a detailed and interesting account of the circumstances under which he himself had been led independently to make his discovery when wandering in 1806 through the Harz. It was thus Thuringia in 1806, as Spix has informed him, but he abstains from any comment on Goethe, and maintained the same blameless silence when Goethe ventured for the first time to claim for himself, in 1820, the merit of having entertained the same idea, or made the discovery, thirty years previously.

The German naturalists held their annual meeting at Jena in 1836, and there Kieser publicly bore testimony, from personal knowledge, to the circumstances and dates of Oken's discovery. However, a few days later, in the "Centralblatt" for 1836, there appeared the following paragraph: "The type-bone is the dorsal vertebra, provided with a hole and divided in processes, every bone being only a modification of it. This idea originated to Oken, who, in 1807, worked in a trisection of the skull published in his "Morphologie" (1820), p. 162. Oken, to whom the treatise was communicated, has pretended that the idea was his own property, and has reaped the honour of it. This accusation again called out Oken, who, in a letter, also published in the "Centralblatt," has refuted his statement in part v. of the "Ilias" (1847). Goethe's osteological essay of 1785, the only one he printed in that century, is on a different subject. In the "Journal" of 1820-1825, Goethe distinctly declares that he had never heard of any work on the vertebral theory of the skull. He could not, therefore, have sent any such essay to Oken before the year 1807. Oken, in reference to his previous endearment of Goethe's pretensions, states that, "being well aware that his fellow-labourers in natural science have approved of the most important of his discoveries," he had accepted the offer of the honorary position of the Judas theory in their judgment. Meckel, Spix, Ulrich, Bojanus, Carus, Cuvier, Geoffroy St Hilaire, Alber, Straus-Durchheim, Owen, Kieser and Lichtenstein had recorded their judgment in his favour and against Goethe's. But the Parmenides of Michtelet's edition of Hegel he could no longer remain silent."

Oken's bold axiom that heat is but a mode of motion of light, and the idea broached in his essay on generation (1805) that the earth is a mass of animated globular monads, or "Sphäritis," are both of the same order as his proposition of the head being a repetition of the trunk, with its vertebrae and limbs. Science would have profited no more from the one idea without a previous disseminating discovery of H. C. D. Will, H. D. Coleridge and M. Faraday, or from the other without the microscopic observations of Robert Brown, J. M. Schleiden and T. Schwann, than from the third notion without the inductive demonstration of the segmental constitution of the skull by Owen. It is questionable, indeed, whether in either case the discoverers of the true theories were excited to their labours, or in any way influenced, by the a priori guesses of Oken; more probable is it that the requisite researches and genuine deductions therefrom were the results of the correlated fitness of the stage of the science and the gifts of its true cultivators at such particular stage.

The following is a list of Oken's principal works: "Grundris des System der Naturphilosophie, der Theorie der Sinne, und der darauf gegründeten Physiologie der Tiere" (1805); "Grundris der Biologie" (1805); "Beiträge zur vergleichenden Zoologie, Anatomie und Physiologie" (along with Kieser, 1806-1807); "Über die Bedeutung der Schädellknochen" (1807); "Über das Corpuscularle" (1807); "Über das Universum als Fortsetzung des Simmerns" (1809); "Über das Gebiß der Seeigel" (1809); "Über die Beziehungen der Farben und der Wärme" (1808); "Grundzüge der physikalischen Lehre" (1813, 1815, 1825); "Handbuch der Naturgeschichte" (1809-1811); "Lehrbuch der Naturgeschichte" (1809-1811); "Grundzüge der Physiologie der Tiere" (1815); "Grundzüge der Physiologie der Tiere" (1821); "Essai d'un système d'anatomie de la physiologie" (1821); "Allgemeine Naturgeschichte" (1822). He also contributed a large number of papers to the "Ibis" and other journals.

OKHOTSK, SEA OF, a part of the western Pacific Ocean, lying between the peninsula of Kamchatka, the Kurile Islands, the Japanese island of Yezo, the island of Sakhalin, and the Amur province of East Siberia. The Sakhalin Gulf and Gulf of Tartary connect it with the Japanese Sea on the west of the island of Sakhalin, and on the south of this island is the La Pérouse Strait.

OKI, a group of islands belonging to Japan, lying due north of the province of Izumo, at the intersection of 36° N. and 133° E. The group consists of one large island called Dogo, and three smaller isles—Chiburi-shima, Nishi-no-shima, and Naka-no-shima—which are collectively known as Dozen. These four islands have a coast-line of 182 m., an area of 132 sq. m., and a population of 63,000. The island of Dogo has two high peaks, Daimanji-mine (2185 ft.) and Omine-yama (2128 ft.). The chief town is Saigo in Dogo, distant about 40 m. from the port of Sakai in Izumo. The name Oki-no-shima signifies "islands in the offing," and the place is celebrated in Japanese history not only because the possession of the islands was much disputed in feudal days, but also because an ex-emperor and an emperor were banished thither by the Hojo regents in the 13th century.

OKLAHOMA (a Choctaw Indian word meaning "red people"), a south central state of the United States of America lying between 33° 35' and 37° 50' lat. and 94° 29' and 105° 42' W. long. It is bounded N. by Colorado and Kansas; E. by Missouri and Arkansas; S. by Texas, from which it is separated in part by the Red river; and W. by the Panamint Desert, 179,000 sq. m., of which 643 sq. m. are water-surface. Although the extreme western limits of the state is the 103rd meridian, the only portion W. of the 106th meridian is a strip of land about 35 m. wide in the present Beaver, Texas and Cimarron counties, and formerly designated as "No Man's Land."

Physiography.—The topographical features of the state exhibit considerable diversity, ranging from wide treeless plains in the W. to rugged and heavily wooded mountains in the E. In general terms, however, the surface may be described as a vast rolling plain having a gentle southern and eastern slope. The elevations above the sea range from 4700 ft. in the extreme N.W. to 350 ft. S.E. The southern and eastern slopes are remarkably uniform; between the northern and southern boundaries E. of the 100th meridian there is a general difference in elevation of from 200 to 300 ft., while from W. to E. there is an average decline of about 3 ft. to the mile. The state has a mean elevation of 1300 ft. with 34,930 sq. m. below 1000 ft; 25,430 sq. m. between 1000 and 2000 ft.; 6500 sq. m. between 2000 and 3000 ft.; and 3600 sq. m. between 3000 and 5000 ft.

The western portion of the Ozark Mountains enters Oklahoma near the centre of the eastern boundary, and extends W.S.W. half way across the state to the highest point of the eastern boundary, overlooking the Red river. In the south central part of the state is an elevated tableland known as the Arbuckle Mountains. In its western portion this tableland attains an elevation of about 1350 ft. above the sea and lies about 200 ft. below the elevation of the Great Plains region at the confluence of the North Fork and South Fork of the Canadian river. With the exception of these isolated clusters of hills the western portion of the state consists almost entirely of rolling prairie. The extreme north-western corner of Oklahoma forming part of the Great Plains region E. of the Rocky Mountains.

The prairies N. of the Arkansas and W. of the Neosho rivers are deeply carved by small streams, and in the western portion of this region they form a series of parallel ridges and sandstones, the easily eroded rocks have been carved into canyons, buttes and mesas. South of the Arkansas river these ledges of sandstone continue as far as Okmulgee, but the evidences of erosion are less marked; and the land is a hilly forested region, with a mixture of hardwood and cedar woodland. In the N.W. four large salt plains form a striking physical feature. Of these the most noted is the Big Salt Plain of the Cimarron river, in Woodward county, which varies in width from 3 m. to 2 m. and extends along the course of the river for a distance of 65,000 ft.

OKLAHOMA, the state capital of Oklahoma, is situated at the north end of the Salt Fork, 14 m. W. of the Salt Fork, and 12 m. S. of the Salt Fork. The city is located on a high bluff overlooking the Salt Fork river, and is well situated for defense. The city is served by the Atchison, Topeka & Santa Fe, and the Missouri, Kansas & Texas railroads, and by the Atchison & Topeka and Santa Fe steam railroads. The city has a large number of hotels, including the Grand, the Hotel Oklahoman, the Hotel Capitol, and the Hotel Caddo, and a number of good business houses. The city is the seat of the University of Oklahoma, the State Normal College, and the State Agricultural College. The city is also the seat of the Atchison & Topeka and Santa Fe railway station, and the Missouri, Kansas & Texas railway station. The city is also the seat of the Atchison & Topeka and Santa Fe railway station, and the Missouri, Kansas & Texas railway station. The city is also the seat of the Atchison & Topeka and Santa Fe railway station, and the Missouri, Kansas & Texas railway station.
Following the slope of the land, the important streams flow from N.W. to S.E. The Arkansas river enters the state from the N. near the 97th meridian, and after following a general south-easterly course, leaves it near the centre of the eastern boundary. Its tributaries from the N. and W. and the Verdigris and nearly all the streams from Illinois—are small and unimportant; but from the S. and W. it receives the waters of much larger streams—the Salt Fork, the Cimarron and the Canadian, with its numerous tributaries. The extended area of the state affords the opportunity for the production of alternate crops which forms the greater part of the southern boundary, and by its tributaries, the North Fork, the Washita and the Kiambas.

Fauna and Flora.—Of wild animals the most characteristic are the black bear, puma, prairie wolves, timber wolves, prairie dogs and antelope. Hawks and turkey buzzards are common types of the larger birds, and the wild turkey, prairie chicken and quail are the principal game birds. The total woodland area of the state was estimated in 1900 at 24,450 sq. m., or one-fifth of the territorial area in 1891. There is a great amount of bottom land, which is exceedingly fertile and yields the crops of the region in a much shorter time than does the upland. The most stunted % of the prairie woodlands is in the extreme E.; among the prairies of the W. timber is seldom found beyond the banks of streams. The most common trees are the various species of the oak and cedar. The pine is confined to the mountains, and is a slow grower, and is remarkably rapid among the bottom lands. These four varieties are of commercial value. Other varieties, most of which are widely distributed, are the ash, pecan, cottonwood, sycamore, elm, maple, hickory, cedar, gum and tallow. The most densely wooded tracts are those along the streams, but there is much bottom land bearing hardwoods. The cottonwood is common along the streams and along the bottom lands. There is a wide variety of timber and the forests are most dense in the extreme N.W. and S.W. of the state. The state's forests are estimated to be worth about $150,000,000.

The climate of the state is of a continental type, with great annual variations of temperature and a rainfall which, though generally sufficient for the needs of vegetation, is considerably less than that of the Atlantic Coast or the Mississippi Valley. The warmest months are June, July and August; in the extreme E. during July the average temperature is 104° F., and in the extreme W. it is 95° F. The state is divided into two rainfall belts, one in which the annual rainfall is 18 to 24 in., and the other in which it is 24 to 30 in. At Oklahoma City, in the centre of the state, the mean annual temperature is 59° F., and for the summer (June, July and August) it is 78°, with an extreme recorded of 104°; for the winter (December, January and February) it is 39°, with an extreme recorded of 17°. For the state as a whole, the mean annual temperature is 61° F.; the mean for the summer is 81°, and for the winter 41°, while the highest and lowest temperatures ever recorded are respectively 114° and 17°. The mean annual precipitation is 37° in., the variation between the E. and W. being about 12 in.

Soils.—The prevailing type of soil is a deep dark-red loam, sometimes (especially in the east central part of the state) made up of a dense, loamy silt loam. The clay loams are quite deep, and the topsoil is more or less clayey. The loess, often thin and containing little humus, also covers large areas in the high, semi-arid plains in the western part of the state.

Livestock.—Stock-raising.—For some time before the first opening to settlement by white men in 1889, the territory now embraced in Oklahoma was largely occupied by great herds of cattle driven in from Texas, and since then, although the opening was principally for agricultural purposes, cattle raising was of great importance. By 1900, 22,988,339 acres, or 52% of the total land surface was included in farms, and 8,574,187 acres, or 37.7% of the farm land was improved. The farm land was divided among 108,000 farms containing 4,414,000 acres (35,685 acres). The number of all live stock was 1,265,189, of which 557,153 were of the middle and E. parts of the state, although the soil of the middle section yields the best crops of wheat. Kafrin corn and sorghum cane are the most common in the W. sections, while the climate is too dry in the extreme S. for the cultivation of cotton. There are many minerals in Oklahoma, but none of them are of great importance. The chief mineral is petroleum, which is found in the extreme S. and is known as the Okla oil. It is estimated that there are 250,000,000 barrels of petroleum in the state, valued at $25,000,000. The production of petroleum in the state is valued at $25,000,000. The total value of minerals produced in the state is valued at $25,000,000. The total value of the state is valued at $25,000,000.

1 The statistics in this article were obtained by adding those for Oklahoma those for Indian Territory, which was combined with it in 1907.

2 The agricultural statistics for 1909 are taken from the Year-Book of the United States Department of Agriculture.
what was Indian Territory) increased from 10,000 barrels in 1901 to 138,011 in 1903, 1,366,728 in 1904 and 45,798,765 in 1908, when it was valued at $17,664,813. Natural gas abounds in the same region, and several strong wells were developed in 1906, and immediately afterwards gas began to be used largely for industrial purposes for which in 1908 the price was from 15 to 15 cents per 1,000 ft. Pipe lines have been constructed. The value of the output increased from $360 in 1902 to $310,137 in 1905 and to $665,159 in 1908.

In the same region are, besides the deposits of asphaltum, but their development has been undertaken only on a small scale: in 1908, 2,402 short tons were put on the market, the value being $23,820. Lead and zinc are found in the same district, the Peoria district, and the Neosho district. The lead (1,400 tons) was valued at $118,356, and the zinc (2,235 tons) at $210,000. The total value of the mineral products in 1908 was $25,868,751.

Manufactures.—The manufactures in 1905 were still largely such as are normally required for agriculture. Measured by the value of the products, 61.8% were represented by flour and gist mill products and cottonseed oil and cake. Among the manufacturing centres are Oklahoma City and Guthrie, and the combined value of their factory products increased from $1,493,698 in 1904 to $4,871,392 in 1908.

Transportation and Commerce.—The navigable waters in Oklahoma are of little importance, and the state is almost wholly dependent on railways as a means of transportation. The first railway was that of the Frisco, the 24th of which was allowed to the territory to Denison, Texas, in 1872. The railway mileage was slowly increased to 1,260 in 1890, and on the 1st of January 1899 was 5,800 m. The Missouri, Kansas & Texas railway crosses the E. part of Oklahoma, and the same line of the same company is continued to the St. Louis & San Francisco, the Atchison, Topeka & Santa Fé, two lines of the Chicago, Rock Island & Pacific, and the Kansas City, Mexico & Orient railways. The Chicago, Rock Island & Pacific also have a line across Oklahoma. Topeka & Santa Fé and the Chicago, Rock Island & Gulf cross the N.W. part. The St. Louis & San Francisco cross the S.E. quarter. A line of the Frisco system extends along the S. border from the Arkansas line to the middle of the state, and with these main lines numerous branches form an extensive network.

Population.—The population of the territory now embraced within the state increased from 95,627 in 1890, when the first census was taken, to 790,391 in 1900, to 205,671, to 1,144,777 in 1907, and to 1,657,155 in 1910. Of the total population in 1900, 779,853, or 97.7%, were native-born. The white population increased from 1,252,554 in 1890 to 1,954,376 in 1907, or 611%, the negro population during the same period from 21,609 to 112,160, or 419%, and the Indian population from 64,456 to 75,072, or 16.3%. In 1890 the Indians and negroes constituted 33.3% of the population of the state. In 1906 (with the addition of 75,000 Mongolians, who numbered 75) constituted only 13.2% of the total. The only Indians who are natives of this region are a few members of the Kiowa, Comanche and Apache tribes. The others are the remnants of a number of tribes collected here from various parts of the country: Choctaws, Chickasaws, Cherokee, Creeks, Seminoles, Osages, Kaws, Poncas, Otoes, Cheyennes, Iowas, Kickapoos, Sauk and Foxes, Sioux, Miamis, Shawnees, Pawnees, Ottawas and several others. Until 1906 the Osages lived on a reservation touching Kansas on the N. and the Arkansas river on the W. (since then almost all allotted); but to the greater portion of the Indians the government has made individual allotments. Only about one-fourth of the so-called Indians are full bloods. A large portion are one-half or more white blood and the Creeks and some others have more or less negro blood. In 1906 there were 5,370,000 communicants of various churches in Oklahoma and Indian Territory, the Methodist Episcopalians being the most numerous, and next to them the Baptists. The population in places having 4000 inhabitants or more increased from 900,000 in 1900 to 2,900,000 in 1907, or 369.9%, while the population outside of such places increased from 760,413 to 1,273,598, or only 75.9%. The principal cities in 1907 were Oklahoma City, Muskogee, Guthrie (the capital), Shawnee, Enid, Ardmore, McAlester and Chickasha.

Administration.—The constitution now in operation was adopted in September 1907, and is that with which the state was admitted into the Union in November of the same year. Amendments may be submitted by a majority of the members elected to both houses of the legislature or through a petition signed by 15% of the electorate, and a proposed amendment becomes a part of the constitution if the majority of the votes cast at a popular election are in favour of it. The legislature may also at any time propose a convention for amending or revising the constitution, but no such convention shall be held with the object of obtaining the approval of the electorate. An elector must be able to read or write (unless he be, or an ancestor was a voter in 1866 or then lived in some foreign nation) and must be 21 years old, and a resident of the state for one year, in the county six months, and in the election precinct 30 days; and women have the privilege of voting at school meetings. General elections are held on the first Tuesday after the first Monday in November in odd-numbered years and party candidates for state, district, county and municipal offices and for the United States Senate are chosen at primary elections held on the first Tuesday in August. The Massachusetts ballot which had been in use in 1897-1899 was again adopted in 1900. Oklahoma has put into its constitution many things which in the older states were left to legislative enactment.

The governor is elected for a term of four years but is ineligible for the next succeeding term. The number of officers whom he appoints is rather limited and for most of his appointments the confirmation of the Senate is required. He is not limited to pardons which he may grant. The constitution reserves to the people the privilege of rejecting any act or any item of any act whenever 5% of the legal voters ask that the matter be voted upon at a general election; and the people may initiate legislation by a petition signed by 8% of the electorate.

For the administration of justice there have been established a supreme court composed of six justices elected for a term of six years; a criminal court of appeals composed of three justices appointed by the governor with the advice and consent of the Senate; twenty-one district courts each with one or more justices elected for a term of four years; a county court in each county with one justice elected for a term of two years; a court of a justice of the peace, elected for a term of two years, in each of six districts of each county, and police courts in the cities. The supreme court has appellate jurisdiction in all civil cases, but its original jurisdiction is restricted to a general control of the lower courts. The criminal court of appeals has jurisdiction in all criminal cases appealed from the district and county courts. The district courts have exclusive jurisdiction in civil actions for sums exceeding $1,000, concurrent jurisdiction with the county courts in civil actions for sums greater than $500 and not exceeding $1,000, original or appellate in criminal cases. The county courts have, besides the concurrent jurisdiction above stated, original jurisdiction in all probate matters, original jurisdiction in civil actions for sums greater than $200 and not exceeding $500, concurrent jurisdiction with the justices of the peace in misdemeanor cases, and appellate jurisdiction in all cases brought from a justice of the peace or a police court.

Local Government.—The general management of county affairs is intrusted to three commissioners elected by districts, but these commissioners are not permitted to incur extraordinary expenses or levy a tax exceeding five mills on a dollar without first obtaining the consent of the people at a general or special election. The
and county officers are a treasurer, clerk, register of deeds, attorney, surveyor, sheriff, assessor and superintendent of public instruction. The counties have been divided into municipal townships, each of which elects a trustee, a clerk and a treasurer, who together constitute the board for internal government affairs. The trustee is also the assessor. Cities or towns having a population of 2000 or more may become cities of the first class whenever a favourable majority vote is obtained at a general or special election held in that city or town, and this question must be submitted to the electors at an election whenever 35% of the legal voters petition for it.

Miscellaneous Laws.—The property rights of husband and wife are practically equal, and either may buy, sell or mortgage real estate, other than the homestead, without the consent of the other. Among the individuals who may be convicted of desertion are those guilty of drunkenness, gross neglect of duty and imprisonment for felony.

Article XII of the constitution exempts from forced sale the homestead of any family in the state to the extent of 160 acres of land in the county in which the family has resided for a period of not less than ten years. If the same does not exceed $5000 and that the claims against it are not for purchase money, improvements or taxes. A corporation commission of three members, elected for a term of six years, is intrusted with the secondary government in control of public service corporations. A state board of arbitration, composed of two farmers, two employers and two employees is authorized to investigate the causes of any strike affecting the public interests, and publish what it finds to be the facts in the case, together with recommendations for amending the laws requiring this investigation. The legislature (1908), were amended and made more radical by the legislature of 1909: a child labour law forbids the employment of children under 14 in factories, workshops, theatres, bowling-alleys, pool-halls, and other places of resort, or on public roads and highways, and no child under 16 is to be employed in such places unless able to read and write simple English sentences or without having attended school during the previous year or six months, in any part of the school term. No (enumerated) dangerous occupations; no child under 16 is to be employed more than 8 hours in any one day, or more than 48 hours in any one week in any gainful occupation other than agriculture, or service and age and schooling certificates are required of children between 14 and 16 years of age in the state. A re-enslavement system for the sale of intoxicating liquors was authorized by the constitution, but the popular vote in 1908 was unfavourable to the continuance of the system, the sentiment seeming to be for rigid prohibition of the sale of intoxicating liquors. A law passed in May 1908 against nepotism (closely following the Texas law of 1907) forbids public officials to appoint (or vote for) any person related to them by affinity or consanguinity within the third degree to any position in the government. This amendment makes it impossible for a public officer to be employed by either a private or public corporation for a term of five years as next friend in cases affecting the property of orphan minors, and has power to investigate complaints against public and private institutions whose charters may be revoked for cause by the commissioner. By act of legislature in 1909 a State Affair was created; it is made of five members appointed by the governor, with duties in connection with the fiscal affairs of all state institutions. Convicts were sent to the state penitentiary of Kansas until January 1909, when it was charged that they were treated cruelly there; in 1909 work was begun on a new state penitentiary.

Banking and Finance.—The unique feature of the banking system (with amendments adopted by the second legislature becoming effective on the 11th of June 1909) is a fund for the guaranty of deposits other than deposits in bills of exchange, for which the governor, lieutenant-governor, president of the board of agriculture, state treasurer and state auditor, levies against the capital stock of each state bank and trust company, organized or existing, under the laws of the state to create a fund equal to 5% of average daily deposits other than the deposits of state funds properly secured. One-fifth of this fund is payable the first year and one-twentieth each year thereafter; 1% of the increase in average deposits is to be paid each year; the aggregate assessment of more than 3% may be made whenever necessary to pay in full the deposits in an insolvent bank; if the guaranty fund is impaired to such a degree that it is not made up by the 2% emergency assessment, the state banking board issues certificates of indebtedness which draw 6% interest, and which are to be secured by mortgages on state lands, may secure its depositors in this manner if it so desires. The bank guaranty law was held to be valid by the United States Supreme Court in 1908 after the attorney-general of the United States had declared that it was unconstitutional.

The revenue for state and local purposes is derived chiefly from taxes. The constitutional limit on the state tax levy is 31 mills on a dollar, and legislation has fixed the limit of the county levy at 5 mills, of the levy in cities at 7, in incorporated towns at 5, in townships at 3, and in school districts at 5. There is a tax on the gross receipts of corporations, a graduated land tax on all holdings exceeding 640 acres, a tax on income exceeding $3500, and a tax on gifts and inheritances. The aggregate amount of indebtedness which the state may have at any time is limited by the constitution to $400,000, save when borrowing is necessary to repel an invasion, suppress an insurrection or defend the state in war.

Education.—The common school system is administered by a state superintendent of public instruction, a state board of education, county superintendents and district boards. The state school board is composed of the state superintendent, who is president of the board; the secretary of state, who serves as vice-president, the state auditor, the secretary of agriculture, the secretary of labor, and the governor and the governor. Each district board is composed of three members elected for a term of three years, one each year. Each district school must be open at least three months each year, and children between the ages of eight and sixteen are required to attend school. There are also country schools, public or private schools in unincorporated towns, and there are state schools of agriculture at Tishomingo and at Warner. The common schools are in large part maintained out of the proceeds of the school lands (about 1,700,000 acres), which are sections 16 and 36 in each township of that portion of the state which formerly constituted Oklahoma Territory, and a Congressional appropriation of $5,000,000 in lieu of these sections in which the former Indian Territory. The university, agricultural and mechanical college and normal schools also are maintained to a considerable extent out of the proceeds of section 13 in several townships. The university owns land valued at $3,670,000. Amendments made in 1890 and 1892 to the constitution by the state, are Epworth University (Methodist Episcopal, 1901) at Oklahoma City, and Kingfisher College at Kingfisher.

Charities and Correctional Institutions.—The state has a hospital for the insane at the State Orphans Home at Pryor Creek, the Oklahoma School for the Blind, Fort Gibson; the Oklahoma School for the Deaf at Sulphur; and the legislature of 1908 appropriated money for the East Oklahoma Hospital for the Insane at Vinita, a School for the Feeble-Minded at Enid, a State Training School for Boys at Wynnewood and a State Training School for Girls (at Granite, greer county) for first-time convicts between the ages of sixteen and twenty-five. Under the constitution the supervision and inspection of charities and institutions of correction is in the hands of a State Commissioner of Charities and Corrections, elected by the people. The commissioner must inspect each year all penal, correctional and eleemosynary institutions, including public hospitals, jails, poorhouses and corporations and organizations of like character. The commissioner has power to enter into agreements with charitable, eleemosynary or other corporations for the care of insane, blind and deaf persons.

History.—With the exception of the narrow strip N. of the most N. section of Texas the territory comprising the present state of Oklahoma was set apart by Congress in 1834, under the name of Indian Territory, for the possession of the five southern tribes (Cherokees, Creeks, Seminoles, Choctaws and Chickasaws) and the Quapaw Agency. Early in 1809 some Creeks in the south-eastern states made known to President Jefferson their desire to remove to hunting grounds W. of the Mississippi, and the President in 1817 allowed them to occupy lands in what is now known as the Kansas and Nebraska Territories. In 1833 they were allowed to occupy lands in what is now Arkansas, by a new treaty. In 1827, they received instead, in 1838, a patent for a wide strip extending along the entire N. border of Indian Territory with the exception of the small section in the N.E. corner which was reserved to the Quapaw Agency. By treaties negotiated in 1820, 1825, 1830 and 1842 the Choctaws received for themselves and the Chickasaws a patent for all that portion of the territory which
lies S. of the Canadian and Arkansas rivers, and by treaties negotiated in 1824, 1833 and 1851 the Creeks received for themselves and the Seminoles a patent for the remainder of the Territory. Many of the Indians of these tribes brought slaves with them from the Southern states and during the Civil War they supported the Confederacy, but when that war was over the Federal government demanded not only the liberation of the slaves but new treaties, partly on the ground that the tribal lands must be divided with the freedmen. By these treaties, negotiated in 1866, the Cherokees gave the United States permission to settle other Indians on what was approximately the western half of their domain; the Seminoles, to whom the Creeks in 1835 had granted their portion of the strip between the Canadian river and its North Fork, ceded all of theirs, and the Creeks, Choctaws and Chickasaws ceded the western half of theirs back to the United States for occupancy by free Indians or by treaty. In the E. portion of the lands thus placed at its disposal by the Cherokees and the Creeks the Federal government within the next seventeen years made a number of small grants as follows: to the Seminoles in 1866, to the Sauk and Foxes in 1867, to the Osages, Kansas, Pottawatomies, Absentee Shawnees and Wichita in 1871-1872, to the Pawnees in 1876, to the Poncas and Nez Percës in 1878, to the Otoes and Missouris in 1881, and to the Iowas and Kickapoos in 1893; in the S.W. quarter of the Territory, also, the Iowas, Comanches, and Kettles were located in 1885; and the Cheyennes and Araphoës in 1889. There still remained unassigned the greater part of the Cherokee Strip besides a tract embracing 1,887,800 acres of choice land in the centre of the Territory, and the agitation for the opening of this to settlement by white people increased until in 1889 a complete title to the central tract was purchased from the Creeks and Seminoles. Soon after the purchase President Benjamin Harrison issued a proclamation announcing that this land would be opened to homestead settlement at twelve o'clock noon, on the 22nd of April 1889. At that hour no less than 20,000 people were on the border, and when the signal was given there ensued a remarkably spectacular race for homes. In the next year that portion of Indian Territory which lay S. of the Cherokee Strip and W. of the lands occupied by the five tribes, together with the narrow strip N. of Texas which had been denied to that state in 1850, was organized as the Territory of Oklahoma. In the meantime negotiations were begun for acquiring a clear title to the unoccupied portion of the Cherokee Strip, for individual allotments to the members of the several small tribes who had received tribal allotments since 1866, and for the purchase of the Indian lands which were used by the government for reservation purposes and for which such Inland allotments had been made. As these negotiations were successful most of the land between the tract first opened and that of the Creeks was opened to settlement in 1891, a large tract to the W. of the center was opened in 1892, a tract S. of the Canadian river and W. of the Chickasaws was opened in 1902, and by 1904 the entire Territory had been opened to settlement with the exception of a tract in the N.E. which was occupied by the Osages, Kaws, Poncas and Otoes. By the treaties with the five southern tribes they were to be permitted to make their own laws so long as they preserved their tribal relations, but since the Civil War many whites had mingled with these Indians, gained control for their own selfish ends of such government as there was, and made the country a refuge for fugitives from justice. Consequently, in 1893, Congress appointed the Dawes Commission to induce the tribes to consent to individual allotments as well as to a government administered from Washington, and in 1898 the Curtis Act was passed for making such allotments and for the establishment of a territorial government. When the allotments were nearly all made Congress in 1906 authorized Oklahoma and Indian Territories to qualify for admission to the Union as one state. As both Territories approved, a constitutional convention (composed of 100 Democrats and 12 Republicans) met at Guthrie on the 29th of November 1906. The constitution framed by this body was approved by the electorate on the 17th of September 1907, and the state was admitted to the Union on the 16th of November.

OKLAHOMA CITY, a city and the county-seat of Oklahoma County, Oklahoma, U.S.A., on the North Fork of the Canadian river, near the geographical centre of the state. Pop. (1890) 4151; (1900) 10,037; (1907) 32,452; (1910) 64,205. It is served by the Atchison, Topeka & Santa Fe, the Chicago, Rock Island & Pacific, the Missouri, Kansas & Texas, and the St Louis & San Francisco railways, and by inter-urban electric lines. It lies partly in a valley, partly on an upland, in a rich agricultural region. The city is the seat of Epworth University (founded in 1901 by the joint action of the Methodist Episcopal Church and the Methodist Episcopal Church, South). Oklahoma City's prosperity is due chiefly to its jobbing trade, with an extensive farming and stock-raising region, but it also has cotton compresses and cotton gins, and various manufactures. The total value of the products in 1905 was $3,670,730. Natural gas is largely used as a fuel. A large settlement was established here on the 22nd of April 1889, the day on which the country was by proclamation declared open for settlement. The city was chartered in 1890.

OKUBO TOSHIMITSU (1832-1878), Japanese statesman, a samurai of Satsuma, was one of the five great nobles who led the revolution in 1868 against the shogunate. He became one of the mikado's principal ministers, and in the Satsuma troubles which followed he was the chief opponent of Saigo Takamori. But the suppression of the Satsuma rebellion brought upon him the personal revenge of Saigo's sympathizers, and in the spring of 1878 he was assassinated by six clansmen. Okubo was one of the leading men of his day, and in 1872 was one of the Japanese mission which was sent round the world to get ideas for organizing the new régime.

OKUMA (SHIGENOBU), COUNT (1838-1922), Japanese statesman, was born in the province of Hizen in 1838. His father was an officer in the artillery, and during his early years his education consisted mainly of the study of Chinese literature. Happily for him, however, he was able to acquire in youth a knowledge of English and Dutch, and by the help of some missionaries he succeeded in obtaining books in those languages on both scientific and political subjects. These works effected a complete revolution in his mind. He had been designed by his parents for the military profession, but the new light which now broke upon him determined him to devote his entire energies to the abolition of the existing feudal system and to the establishment of a constitutional government. With impetuous zeal he urged his views on his countrymen, and though he took no active part
in the revolution of 1688, the effect of his opinions exercised no slight weight in the struggle. Already he was a marked man, and no sooner was the government reorganized, with the mikado as the sole wielder of power, than he was appointed chief assistant in the department of foreign affairs. In 1869 he succeeded to the post of secretary of the joint departments of the interior and of finance, and for the next fourteen years he devoted himself wholly to politics. In 1870 he was made a councillor of state, and a few months later he accepted the office of president of the commission which represented the Japanese government at the Vienna Exhibition. In 1872 he was again appointed minister of finance, and when the expedition under General Seigō was sent to Formosa (1874) to chastise the natives of that island for the murder of some shipwrecked fishermen, he was nominated president of the commission appointed to supervise the campaign. By one of those waves of popular feeling to which the Japanese people are peculiarly liable, the nation which had supported him up to a certain point suddenly veered round and opposed him with heated violence. So strong was the feeling against him that on one occasion a would-be assassin threw at him a dynamite shell, which blew off one of his legs. During the whole of his public life he recognized the necessity of promoting education. When he resigned office in the early 'eighties he established the Semmon Gako, or school for special studies, at the cost of the 30,000 yen which had been voted him when he received the title of count, and subsequently he was instrumental in founding other schools and colleges. In 1896 he joined the Matsukata cabinet, and resigned in the following year in consequence of intrigues which produced an estrangement between him and the prime minister. On the retirement of Marquis Ito in 1898 he again took office, combining the duties of premier with that of minister of foreign affairs. But dissensions having arisen in the cabinet, he resigned a few months later, and retired into private life, cultivating his beautiful garden at Waseda near Tókyō.

OLAF, the name of five kings of Norway.

OLAF I. TRYGVGVESSON (869–900) was born in 869, and began his heroic career in exile. It is even said that he was bought as a slave in Esthonia. After a boyhood spent in Novgorod under the protection of King Valdemar, Olaf fought for the emperor Otto III. under the Wendish king Buriaslav, whose daughter he had married. On her death he followed the example of his countrymen, and harried in France and the British Isles, till, in a good day for the peace of those countries, he was converted to Christianity by a hermit in the Scilly Islands, and his marauding expeditions ceased since he would not harry those of his new faith. In England he married Gyda, sister of Olaf Kvaran, king of Dublin, and it was only after some years spent in administering her property in England and Ireland that he set sail for Norway, fired by reports of the unpopularity of its ruler Earl Haakon. Arriving in Norway in the autumn of 905, he was unanimously accepted as king, and at once set about the conversion of the country to Christianity, undeterred by the obstinate resistance of the people. It has been suggested that Olaf's ambition was to rule a united, as well as a Christian, Scandinavia, and we know that he made overtures of marriage to Sigrid, queen of Sweden, and set about annexing to his fleet, when negotiations fell through owing to her obstinate heathenism. He made an enemy of her, and did not hesitate to involve himself in a quarrel with King Sveyn of Denmark by marrying his sister Thyr, who had fled from her heathen husband Burislav in defiance of her brother's authority. Both his Wendish and his Irish wife had brought Olaf wealth and good fortune, but Thyr was his undoing, for it was on an expedition undertaken in the year 1000 to wrest her lands from Burislav that he was waylaid off the island Svold, near Rügen, by the combined Swedish and Danish fleets, together with the ships of Earl Haakon's sons. The battle ended in the annihilation of the Norwegians. Olaf fought to the last on his great vessel, the "Long Snake," the mightiest ship in the North, and finally leapt overboard and was no more seen. Full of energy and daring, skilled in the use of every kind of weapon, genial and open-handed to his friends, implacable to his enemies, Olaf's personality was the ideal of the heathendom he had trodden down with such reckless disregard of his people's prejudices, and it was no doubt as much owing to the popularity his character won for him as to the strength of his position that he was able to force his will on the country with impunity. After his death he remained the hero of his people, who whispered that he was yet alive and looked for his return. "But however that may be," says the story, "Olaf Tryggveson never came back to his kingdom in Norway."

OLAF II. Haroldsson (905–1030), king from 1016–1029, called during his lifetime "the Fat," and afterwards known as St. Olaf, was born in 905, the year in which Olaf Tryggveson came to Norway. After some years' absence in England, fighting the Danes, he returned to Norway in 1015 and declared himself king, obtaining the support of the five petty kings of the Uplands. In 1016 he defeated Earl Sveyn, hitherto the virtual ruler of Norway, at the battle of Nesje, and within a few years had won more power than had been enjoyed by any of his predecessors on the throne. He had annihilated the petty kings of the South, had crushed the aristocracy, enforced the acceptance of Christianity, treated the abbeys with arrogance, and in the Orkney Islands, had humbled the kings of Sweden and married his daughter in his despite, and had conducted a successful raid on Denmark. But his success was short-lived, for in 1029 the Norwegian nobles, seething with discontent, rallied round the invading Knut the Great, and Olaf had to flee to Russia. On his return a year later he fell at the battle of Stiklestad, where his own subjects were arrayed against him. The succeeding years of disunion and misrule under the Danes explain the belated affection with which his countrymen came to regard him. The cunning and cruelty which marred his character were forgotten, and his services to his church and country remembered. Miracles were worked at his tomb, and in 1064 he was canonized and was declared the patron saint of Norway, whence his fame spread throughout Scandinavia and even to England, where churches are dedicated to him. The Norwegian order of knighthood of St Olaf was founded in 1847 by Oscar I., king of Sweden and Norway, in memory of this king.

The three remaining Norwegian kings of this name are persons of minor importance (see Norway: History).

OLAF, or Anlaf (d. 981), king of the Danish kingdoms of Northumbria and of Dublin, was a son of Sitric, king of Deira, and was related to the English king Æthelstan. As his name indicates he was of Norse descent, and he married a daughter of Constantine II., king of the Scots. When Sitric died about 927 Æthelstan annexed Deira, and Olaf took refuge in Scotland and in Ireland until 937, when he was one of the leaders of the formidable league of princes which was destroyed by Æthelstan at the famous battle of Brunanburh. Again he sought a home among his kinsfolk in Ireland, but after Æthelstan's death in 940 he or Olaf Godfreyson was recalled to England by the Northumbrians. Both crossed over, and in 941 the new English king, Edmund, gave up Deira to the former. The peace between the English and the Danes did not, however, last long. Wulfstan, archbishop of York, sided with Olaf; but in 944 this king was driven from Northumbria by Edmund, and crossing over to Ireland he ruled over the Danish kingdom of Dublin. From 940 to 952 he was again king of Northumbria, until he was expelled once more, and he passed the remainder of his active life in warfare in Ireland. But in 980 his dominion was shattered by the defeat of the Danes at the battle of Tarn. He went to Iona, where he died probably in 981, although one account says he was in Dublin in 904. This, however, is unlikely. In the sagas he is known as Olaf the Red.

This Olaf must not be confused with his kinsman and ally, Olaf (d. 941), also king of Northumbria and of Dublin, who was a son of Godfrey, king of Dublin. The latter Olaf became king of Dublin in 934; but he was in England in 937, as he took part in the fight at Brunanburh. After this event he returned to Ireland, but he appears to have acted for a very short
time as joint king of Northumbria with Olaf Sitricon. It is possible that he was the "Olaf of Ireland" who was called by the Northumbrians after Æthelstan's death, but both the Olafs appear to have accepted the invitation. He was killed in 941 at Tynningham near Dunbar.

**ÖLAND**, an island in the Baltic Sea, next to Gotland the largest belonging to Sweden, stretching for 85 m. along the east coast of the southern extremity of that country, from which it is separated by Kalmar Sound which is from 5 to 15 m. broad. The greatest breadth of the island is 10 m., and its area 519 sq. m. Pop. (1900) 30,408. Consisting for the most part of Silurian limestone, and thus forming a striking contrast to the mainland with its granite and gneiss, Öland is further remarkable on account of the peculiarities of its structure. Down the west side for a considerable distance runs a limestone ridge, rising usually in terraces, but at times in steep cliffs, to an extreme height of 200 ft.; and along the east side there is a parallel ridge of sand, resting on limestone, never exceeding 90 ft. These ridges, known as the Western and Eastern Landborgar, are connected towards the north and the south by belts of sand and heath; and the hollow between them is occupied by a desolate and almost barren tract: the southern portion, or Alvar (forming fully half of the southern part of the island), presents a surface of bare red limestone with large spots of yellow sand, andcalcined by the heat refracted from the surrounding heights. The northern portion is covered at best with a copse of hazel bushes. Outside the ridges, however, Öland has quite a different aspect, the hillsides being not infrequently clothed with clumps of trees, while the narrow strip of alluvial coast-land, with its cornfields, windmills, villages and church towers, appears fruitful and prosperous. There are a few small streams in the island; and one lake, Hornsjö, about 3 m. long, deserves mention. Of the fir woods which once clothed a considerable area in the north the Böda crown-park is the only remnant. Grain, especially barley, and sandstone, are exported from the island, and there is cement works. A number of monuments of unknown age exist, including stones (stenstagningar) arranged in groups to represent ships. The only town is Borgholm, a watering-place on the west coast, with one of the finest castle ruins in Sweden. The town was founded in 1817, but the castle, dating at least from the 13th century, was one of the strongest fortresses, and afterwards, as erected by the architect Nicodemus Tessin the elder (1615-1681), one of the most stately palaces in the country. The island was joined in 1824 to the administrative district (län) of Kalmar. Its inhabitants were formerly styled Öningar, and show considerable diversity of origin in the matter of speech, local customs and physical appearance.

From the raid of Ragnar Lodbrok's sons in 775 Öland is frequently mentioned in Scandinavian history, and especially as a battleground in the wars between Denmark and the northern kingdoms. In the 15th century it formed a separate legislative and administrative unity.

**OLAVUS MAGNUS**, or MAGNI (Magnus, i.e. Stora, great, being the family name, and not a personal epithet), Swedish ecclesiastic and author, was born at Linköping in 1490 and died at Rome in 1556. Like his elder brother, Johannes Magnus, he obtained several ecclesiastical preferments (a canonry at Upsala and at Linköping, and the archdeaconry of Södermanland), and was employed on various diplomatic services (such as a mission to Rome, from Gustavus V., to procure the appointment of Johannes Magnus as archbishop of Upsala); but on the success of the reformation in Sweden his attachment to the old church led him to accompany his brother into exile. Settling at Rome, from 1527, he acted as his brother's secretary, and ultimately became his successor in the (now titular) archbishopric of Upsala. Pope Paul III., in 1546, sent him to the council of Trent; later, he became canon of St Lambert in Liège; King Sigismund I. of Poland also offered him a canonry at Posen; but most of his life, after his brother's death, seems to have been spent in the monastery of St Brigitta in Rome, where he subsisted on a pension assigned him by the pope. He is best remembered as the author of the famous Historia de Gentibus Septentrionalibus (Rome, 1555), a work which long remained for the rest of Europe the chief authority on Swedish matters and is still a valuable repertory of much curious information in regard to Scandinavian customs and folk-lore.

The History was translated into Italian (Venice, 1565); German (Strassburg, 1567), English (London, 1658) and Dutch (Amsterdam, 1665); abridgments of the work appeared also at Antwerp (1558 and 1562), Paris (a French abridged version, 1561), Amsterdam (1586), Frankfort (1618) and Leiden (1625). Olavus also wrote a Travels in terrarum septentrionalium partem, and that of 30 years (1556). It bears his name in commemoration of its detection by him. He also took a leading part in the discovery of the minor planets, re-identified Ceres on the 1st of January 1802, and detected Pallas on the 28th of March following. His bold hypothesis of their origin by the disruption of a primitive large planet (Monatliche Correspondenz, vi. 88), although now discarded, received censure from the finding of Juno by Harding, and of Vesta by himself, in the precise regions of Cetus and Virgo where the nodes of such supposed planetary fragments should be situated. Olbers was deputed by his fellow-citizens to assist at the baptism of the king of Rome on the 9th of June 1811, and he was a member of the corps législatif in Paris 1812-1815. He died on the 2nd of March 1840, at the age of eighty-one. He was twice married, and one son survived him.

**OLBIA**, the chief Greek settlement in the north-west of the Euxine. It was generally known to the Greeks of Hellas as Barcopolis, though its actual site was on the right bank of the Hypanis (Bug) 4 m. above its junction with the estuary of the Borysthenes river (Dnieper). Eusebius says that it was founded from Miletus c. 650 B.C., a statement which is borne out by the discovery of Mileian pottery of the 7th century. It first appears as enjoying friendly relations with its neighbours the Scythians and standing at the head of trade routes leading far to the north-east (Herodotus iv.). Its wares also penetrated northward. It exchanged the manufactures of Ionia and, from the 5th century, of Attica for the slaves, hides and corn of Scythia. Changes of the native population (see SCYTHIA) interrupted this commerce, and the city was hard put to it to
OLBIA—OLD-AGE PENSIONS

defend itself against the surrounding barbarians. We know of these difficulties and of the democratic constitution of the city from a decree in honour of Protagenes in the 3rd century B.C. (Gr. Ins. ii. 2058, Inscrip. Sept. Ponti. 223). In the following century it fell under the rule of Scylurus, whose name appears on its coins, and when its power was broken by Mithradates VI. the Great, of Pontus, it submitted to the latter. About 50 B.C. it was entirely destroyed by the Getae and lay waste for many years. Ultimately at the wish of, and, to judge by the coins, under the protection of the natives themselves, it was restored, but Dio Chrysostom (Or. xxxvi.), who visited it about A.D. 83, gives a curious picture of its poor state. During the 2nd century A.D. it prospered better with Roman support and was quite flourishing from the time of Septimius Severus, when it was incorporated in Lower Moesia, to 248, when its coins came to an end, probably owing to its sack by the Goths. It was once more restored in some sort and lingered on to an unknown date. Excavations have shown the position of the old Greek walls and of those which enclosed the narrower site of the Roman city, an interesting Hellenistic house, and cemeteries of various dates. The principal cult was that of Achilles Pontarches, to whom the archons made dedications. It has another centre at Leuce (Phidonisi) and at various points in the north Euxine. Secondary was that of Apollo Prostates, the patron of the strategi; but the worship of most of the Hellenic deities is testified to in the inscriptions. The coinage begins with large round copper pieces comparable only to the Roman aes grave and smaller pieces in the shape of dolphins; these both go back into the 6th century B.C. Later the city adopted silver and gold coins of the Aegistic standard.

See E. H. Minns, Scythians and Greeks (Cambridge, 1909); V. P. Latschev, Olbia (St Petersburg, 1887, in Russian). For inscriptions, Bocckh, C.I.G. vol. ii.; V. V. Latschev, Inscrip. Ori sept. Ponti Euxini, vols. i. and iv. For excavations, Reports of B. V. Pharmacovsky, (Ber. d. Kom. für. arch. in Chron. 1901 sqq.), and Bulletin of the same, Nos. 8. 13, 6c., summarized in Archäologischer Anzeiger (1903 sqq.).

OLBIA (Gr. Ὠξῆα, i.e. happy; mod. Terranova Pausania, q.v.), an ancient seaport city of Sardinia, on the east coast. The name indicates that it was of Greek origin, and tradition attributes its foundation to the Boeotians and Thespians under Iolaus (see Sardinia). Pais considers that it was founded by the Phocaens of Massilia before the 4th century B.C. (in Tampeni, op. cit. p. 83). It is situated on low ground, at the extremity of a deep recess, now called the Golfo di Terranova. It was besieged unsuccessfully by L. Cornelius Scipio in 259 B.C. Its territory was ravaged in 210 B.C. by a Carthaginian fleet. In Roman times it was the regular landing-place for travellers from Italy. Cicero notes the receipt of a letter from his brother from Olbia in 50 B.C., and obviously shared the prevailing belief as to the unhealthy condition of Sardinia. Traces of the Roman city have not been found. The line of the Roman city walls has been determined on the N. and E., the N.E. angle being at the ancient harbour, which lay to the N. of the modern city (Notaie degli Scavi, 1900, p. 224). Among the inscriptions are two tomstones, one of an imperial freedwoman, the other of a freedman of Acte, the concubine of Nero; a similar tombstone was also found at Carales, and tiles bearing her name have been found in several parts of the island, but especially at Olbia, where in building a modern house in 1881 about one thousand were discovered. Pais (op. cit. 89 sqq.) attributes to Olbia an inscription now in the Campo Santo at Pisa, an epistle bearing the words “Cereri sacrum Claudia Aug. lib. Acte,” and made of Sardinian (? ) granite. In any case it is clear that Acte must have had considerable property in the island (Corpo. Inscr. Lat. x. 7980). Discoveries of buildings and tombs have frequently occurred within the area of the town and in its neighbourhood. Some scanty remains of an aqueduct exist outside the town, but hardly anything else of

antiquity is to be seen in situ. A large number of milestones, fifty-one in all, with inscriptions, and several more with illegible ones, belonging to the first twelve miles of the Roman road from Olbia to the Massilia, have been discovered, and are now kept in the church of S. Niccolò dei Scavi, 1888, p. 535; 1889, p. 258; 1892, pp. 217, 366; Classical Review, 1889, p. 228; 1890, p. 65; P. Tamponi, Sillghe Epigranica, Olbienne, Sassari, (1895). This large number may be accounted for by the fact that a new stone was often erected for a new emperor. They range in date from A.D. 245 to 375 (one is possibly of Domitian). The itineraries state that the main road from Carales to Olbia ran through the centre of the island to the east of Gennargentu (see Sardinia); but a branch certainly diverged from the main road from Carales to Turris Libisonis (which kept farther west, more or less along the line followed by the modern railway) and came to Olbia. The distance by both lines is much the same; and all these milestones belong to the last portion which was common to both roads.

(T. As.)

OLD-AGE PENSIONS. The provision of annuities for aged poor by the state was proposed in England in the 18th century—e.g. by Francis Masera, curator baron of the Exchequer, in 1772, and by Mr. Mark Rolle, M.P., in 1787. Suggestions for subsidizing friendly societies have also been frequent—e.g. by T. Paine in 1795, tentatively in Sturges Bourne's Report on the Poor Laws, 1817, and by Lord Lansdowne in 1837. The subject again became prominent in the latter part of the 19th century. In 1884, Mr. Blackley, who had a heavy collection of tax, proposed to compel every one to insure with a state department against sickness and old age, and essentially his scheme was one for the relief of the ratepayers and a more equitable readjustment of the poor-rate. The terms provisionally put forward by him required that every one in youth should pay £10, in return for which the state was to grant 8s. a week sick allowance and 4s. pension after seventy. These proposals were submitted to the Select Committee on National Provident Insurance, 1885—1887. This body reported unfavourably, more especially on the sick insurance part of the scheme, but the idea of old-age pension survived, and was taken up by the National Provident League, of which Mr. (afterwards Sir) J. Rankin, M.P., was chairman. The subject was discussed in the constituencies and expectation was aroused. An unofficial parliamentary committee was formed, with Mr. J. Chamberlain as chairman. This committee published proposals in March 1892, which show a very interesting change of attitude on the part of the promoters. Compulsion, which at the earlier period had found favour with Canon Blackley, Sir J. Rankin and even Mr. Chamberlain, was no longer urged. The annuitant was no longer required to pay a premium adequate to the benefits promised, as in Canon Blackley's proposal. The proposal was now introduced to double every half-crown of pension derived by members from their friendly societies. This suggestion was criticized, even by supporters of the principle of state aid, on the ground that unless a pension was gratuitous, the class from which pauperism is really drawn could not profit by it. Mr. Charles Booth in particular took this line. He accordingly proposed that there should be a general endowment of old age, 5s. a week to every one at the age of sixty-five. This proposal was calculated to involve an expenditure of £18,000,000 for England and Wales and £34,000,000 for the United Kingdom, exclusive of the cost of administration. While Mr. Booth severely criticized the weak points of the contributory and voluntary schemes, their most influential advocate, Mr. Chamberlain, did not spare Mr. Booth's proposals. Speaking at Highbury, for instance, on the 24th of May 1899, he described Mr. Booth's universal scheme as "a gigantic system of out-door relief for every one, good and bad, thirsty and unthriftly, the waster, drunkard and idle, as well as the industrious," and very forcibly stated his inability to support it.
In 1893 Mr Gladstone referred the whole question to a royal commission (Lord Aberdare, chairman). A majority report, adverse to the principle of state pensions, was issued in 1895. A minority report, signed by Mr Chamberlain and others, dissented, mainly on the ground that public expectation would be disappointed if nothing was done. In 1896 Lord Salisbury appointed a committee “of experts” (Lord Rothschild, chairman) to report on schemes submitted, and, if necessary, to devise a scheme. The committee were unable to recommend any of the schemes submitted, and added that, “we ourselves are unable, after repeated attempts, to devise any proposal free from grave inherent disadvantages.” This second condemnation was not considered conclusive, and a select committee of the House of Commons (Mr Chaplin, chairman) was appointed to consider the condition of “the aged deserving poor.” After an ineffectual attempt by Mr Chaplin to induce the committee to drop the pension idea, and to consider the provision made for the aged by the poor law, the committee somewhat hastily promulgated a scheme of gratuitous pensions for persons possessing certain qualifications. Of these the following were the most important: age of sixty-five; no conviction for crime; no poor-law relief, “unless under exceptional circumstances,” within twenty years; non-possession of income of 10s. a week; proved industry, or proved exercise of reasonable providence by some definite mode of thrift. The committee refrained from explaining the machinery and from estimating the cost, and suggested that this last problem should be submitted to yet another committee.

Accordingly a departmental committee (chairman, Sir E. Hamilton) was appointed, which reported in January 1900. The estimated cost of the above plan was, by this committee, calculated at £10,300,000 in 1901, rising to £15,650,000 in 1921. Mr Chaplin had publicly suggested that £2,000,000, the proceeds of a 1½% duty on corn, would go a long way to meet the needs of the case—a conjecture which was obviously far too sanguine. These unfavourable reports discouraged the more responsible advocates of state pensions. Mr Chamberlain appealed to the friendly societies to formulate a plan, an invitation which they showed no disposition to accept. Efforts continued to be made to press forward Mr Booth’s universal endowment scheme or some modification of it. To this Mr Chamberlain declared his hostility. And here the matter rested, till in his Budget speech in 1907 Mr Asquith asked the Liberal government to start a scheme in 1908.

Accordingly there was passed the Old-Age Pensions Act, which carried into effect a scheme for state pensions, payable as from the 1st of January 1909 to persons of the age of 70 years and over. The act grants a pension according to a graduated scale of not exceeding 5s. a week to every person, male and female, who fulfils certain statutory conditions, and at the same time is not subject to certain disqualifications. The statutory conditions, as set out in §1 of the act, are: (1) the person must have attained the age of seventy; (2) must satisfy the pension authorities that for at least twenty years up to the date of receipt of pension he has been a British subject and has had his residence in the United Kingdom; and (3) the person must satisfy the pension authorities that his yearly means do not exceed £31, 10s. In §4 of the act there are elaborate provisions for the calculation of yearly means, but the following may be particularly noticed: (1) in calculating the means of a person being one of a married couple living together in the same house, the means shall not in any case be taken to be a less amount than half the total means of the couple, and (2) if any person directly or indirectly deprives himself of any income or property in order to qualify for an old-age pension, it shall nevertheless be taken to be part of his means. The disqualifications are: (1) receipt of poor-law relief (this qualification was specially removed as from the 1st of January 1911); (2) habitual failure to work (except in the case of those who have continuously for ten years up to the age of sixty made provision for their future by payments to friendly, provident or other societies or trade unions; (3) detention in a pauper or criminal lunatic asylum; (4) imprisonment without the option of a fine, which disqualifies for ten years; and (5) liability to disqualification for a period not exceeding ten years in the case of an habitual drunkard. The graduated scale of pensions is given in a schedule to the act, and provide that when the yearly means of a pensioner do not exceed £21 he shall have the full pension of 5s. a week, which diminishes by 1s. a week for every addition of £2, 12s. 6d. to his income, until the latter reaches £31, 10s., when no pension is payable. The pension is paid weekly, on Fridays (§5), and is inalienable (§6).

All claims for, and questions relating to, pensions are determined by the pension authorities. They are: (1) pension officers appointed by the Treasury from among inland revenue officers; (2) a central pension authority, which is the Local Government Board or a committee appointed by it, and (3) local pension committees appointed for every borough and urban district with a population of over 20,000, and for every county.

During the first three months of the year 1909, in which the act came into operation, there were 537,831 claims made for pensions: 490,755 in England and Wales, 85,408 in Scotland, and 261,668 in Ireland. Of these claims a total of 647,494 were granted: 393,700 in England and Wales, 70,294 in Scotland, and 183,500 in Ireland. The pensions in force on the 31st of March 1909 were as follows: 582,565 of 5s., 23,616 of 4s., 23,275 of 3s., 11,420 of 2s., and 6,609 of 1s. By the 30th of September the total amount of money paid to 682,688 pensioners was £8,063,658, and in the estimates of 1909–1910 a sum of £8,750,000 was provided for the payment of pensions.

**Germany.**—The movement in favour of state aid to provision for old age has been largely due to the example of Germany. The German system (which for old age dates from 1891) is a form of compulsory and contributory insurance. One half of the premium payable is paid by the employer, the other half by the employer. The state adds a subvention to the allowances paid to the annuitant. (See Germany.)

**France.**—By a law of April 1910 a system of old-age pensions, designed to come into operation in 1911, was adopted. It is a contributory system, embracing all wage-earners, with the exception of railway servants, miners and sailors on the special reserve list of the navy. It applies also to small landowners, tenant farmers and farm labourers. All are eligible for a pension at the age of 65, if in receipt of less than £120 a year. The actual rente or pension is calculated on the basis of the total obligatory contribution, together with a fixed viagère or state annuity. Male wage-earners are required to contribute 9 francs a year, and females 6 francs, the contributions being paid out of the weekly wages. The largest pension obtainable is for life contributions and amounts to 414 francs. A clause in the act permits wage-earners to claim the rente at the age of 55 on a proportionately reduced scale without the viagère. The total cost of providing pensions in 1911 is estimated at over £5,500,000.

**Denmark.**—The Danish system of old-age pensions was instituted by a law of 1891, and has been extended by further acts of 1902 and 1908. By the law of 1891 the burden of maintaining the aged was in part transferred from the local to the national taxes, and relief from this latter source was called a pension. Recipients of public assistance must be over 60 years of age, they must be of good character and for 5 years previous to receipt must have had their domicile in Denmark without receiving public charity. Such public assistance may be granted either in money, or kind, or by residence in an institution, such as an hospital. The assistance given, whatever it may be, must be sufficient for maintenance, and for attendance in case of illness. The actual amount is determined by the poor-law authorities, but all private assistance amounting to more than 100 kroner (£5, 13s.) a year is taken into account in measuring the poverty of the applicant. The cost of assistance is met in the first case by the community in which the recipient is domiciled, but half the amount is afterwards refunded by the state. In 1907–1908, 71,185 persons were assisted—53,008 by money and 18,177 otherwise. The total expenditure was £486,200, £242,660 being refunded by the state.
New Zealand.—In 1898 a bill, introduced by the Rt. Hon. R. J. Seddon, premier, became law which provided for the payment of an old-age pension out of the consolidated fund (revenue of the general government) to persons duly qualified, without contribution by the pensioner, but subject to proof of five years' residence in the colony, and who have resided for 25 years. They must be free from conviction for lesser legal offences for 12 years, and for more serious breaches of the law for 25 years, previous to the application for pensions, claimants must have obtained a record of sobriety and respectability for five years. Their yearly income must not exceed £52, and they must not be owners of property exceeding in value £270. Aliens, aborigines, Chinese, and any others of like character, are excluded. The pension is £15 per annum, but for each £1 of yearly income over and above £50, £1 is deducted from the amount of the pension. Applications have to be made to the deputy registrar of the district in which the person resides. The clerk for the purposes of the act is required to make all the necessary investigations, while others point to the invidious character of the examination required in proving the necessary degree of poverty, and allege that the arrangement penalizes the thinnest members of the community. Evidence, however, is given in support of the necessity of a more or less fraudulent character, between members of a family.

Victoria.—By the Old-Age Pensions Act, 1900, £75,000 was appropriated for the purpose of paying a pension of not more than £10. It is to be shown when evidence is necessary, that the pensioner must be 65 years of age or permanently disabled, must fill up a declaration that he has lived twenty years in the state; has not been convicted of any crime, and that his income and property do not exceed a given sum (the regulation of this and other details is intrusted to the governor in council). Further sums were subsequently appropriated to the purposes of the act.

OLDBURG, an urban district in the Oldbury parliamentary division of Worcestershire, England, 3 m. W. of Birmingham, on the Great Western and London & North-Western railways and the Birmingham canal. Pop. (1901) 25,191. Coal, iron and limestone. Coal is mined from one coalfield to the north, and from other collieries. Limestone, sandstone, and clay are used in the numerous kilns. The town grows its own vegetables, and the products of the local manufacturing and engineering industry are sold through the retail trade and the railway goods yards. The chief manufactures are chemicals and chemical works, carriage-carrying works, iron, edge- tool, nail and steel works, maltings, corn-mills, and brick and tile kilns. The urban district includes the townships of Langley and Warley.

OLDCASTLE, SIR JOHN (d. 1417), English Lollard leader, was son of Sir Richard Oldcastle of Almeley in Herefordshire. He is first mentioned as serving in the expedition to Scotland in 1400, when he was probably quite a young man. Next year he was in charge of Bught castle in Brec, and serving all through the Welsh campaigns won the friendship and esteem of Henry, the prince of Wales. Oldcastle represented Herefordshire in the parliament of 1404. Four years later he married Joan, the heiress of Cobham, and was thereupon summoned to parliament as Lord Cobham in her right. As a trusted supporter of the prince, Oldcastle held a high command in the expedition which the young Henry sent to France in 1411. Lollard had many supporters in Herefordshire, and Oldcastle himself had adopted Lollar opinions before 1414 when the churches in Kent was laid under interdict for unlicensed preaching. In the conviction which met in March 1413, shortly before the death of Henry IV., Oldcastle was at once accused of heresy. But his friendship with the new king prevented any decisive action till convincing evidence was found in a book belonging to Oldcastle, which was discovered in a shop in Paternoster Row. The matter was brought before the king, who desired that nothing should be done till he had tried his personal influence. Oldcastle declared his readiness to submit to the king “all his fortune in this world,” but was firm in his religious beliefs. When he fled from Windsor to his own castle at Cowling, Henry at last consented to a prosecution. Oldcastle refused to obey the archbishop’s repeated citations, and it was only under a royal warrant that he at last appeared before the ecclesiastical court on the 23rd of September. In a confession of his faith he declared his belief in the sacraments and the necessity of penance and true confession; but to put hope, faith or trust images was the great sin of idolatry. But he could not get over to the orthodox doctrine of the sacrament as stated by the bishops, nor admit the necessity of confession to a priest. So on the 25th of September he was convicted as a heretic. Henry was still anxious to find a way of escape for his old comrade, and granted a respite of forty days. Before that time had expired Oldcastle escaped from the Tower by the help of one William Fisher, a parchment-maker of Smithfield (Riley, Memoirs of London, 641). Oldcastle now put himself at the head of a wide-spread Lollar conspiracy, which assumed a definitely political character. The design was to seize the king and his brothers during a Twelfth-night mumming at Etham, and perhaps, as was alleged, to establish some sort of commonwealth. Henry, forewarned of their intention, removed to London, and when the Lollards assembled in force in St. Giles’s Fields on the 10th of January they were easily dispersed. Oldcastle himself escaped into the English and Breton navies, but his hiding-place was discovered on the 26th of February by the search of that officer. Apparently he was privy to the Scrope and Cambridge plot in July 1415, when he stirred some movement in the Welsh Marches. On the failure of the scheme he went again into hiding. Oldcastle was no doubt the instigator of the abortive Lollar plots of 1416, and appears to have intrigued with the Scots. But at last his hiding-place was discovered and in November 1417 he was captured by the Lord Charlton of Powis. Oldcastle who was “sore wounded ere he would be taken,” was brought to London in a horse-litter. On the 14th of December he was formally condemned, on the record of his previous conviction, and that same day was hung in St. Giles’s Fields, and burnt “gallows and all.” It is not clear that he was burnt alive.

Oldcastle died a martyr. He was no doubt a man of fine quality, but circumstances made him a traitor, and it is impossible altogether to condemn his execution. His unpopular opinions and his friendship with Henry V. created a traditional scandal which continues to this day. A good account of the life of Oldcastle is found in Dr. Basset’s Life of Henry V., written before 1588, Oldcastle figures as the prince’s boon companion. When Shakespeare adapted that play in Henry IV., Oldcastle still appeared; but when the play was printed in 1598 Falstaff’s name was substituted, in deference, as it is said, to the then Lord Cobham. Though the fat knight still remains “my old lad of the Castle,” the stage character has nothing to do with the Lollar leader.

Bibliography.—The record of Oldcastle’s trial is printed in Fasciculi Zizaniorum (Rolls series) and in Wilkin’s Concilia, iii. The chief speeches are given in Gestis Henrici Quinti (Eng. Hist. Soc.) and in Walsingham’s Historia Anglica. There have been many lives of Oldcastle, mainly based on The Acts and Monuments of John Foxe, who in his description of Oldcastle on pp. 156 of the First Edition (1563) published in 1544. For notes on Oldcastle’s early career consult J. H. Wylie, History of England under Henry IV. For literary history see the Introductions to Richard James’s Life Lancasterense (Cheetham Soc., 1845) and to Grosart’s edition of the Poems of Richard James (1880). See also W. Barske, Oldcastle-Falstaff in der englischen Literatur bis zu Shakespeare (Palaestra, 1. Berlin, 1905). For a recent Life, see W. T. Waugh in the English Historical Review, vol. xx. (C. L. K.)
OLD CATHOLICS (Ger. Altkatholiken), the designation assumed by those members of the Roman Catholic Church who refused to accept the decrees of the Vatican Council of 1870 defining the dogma of papal infallibility (see Vatican Council and Infallibility) and ultimately set up a separate ecclesiastical organization on the episcopal model. The Old Catholic movement, at the outset at least, differed fundamentally from the Protestant Reformation of the 16th century in that it aimed not at any drastic changes in doctrine but at the restoration of the ancient Catholic system, founded on the diocesan episcopate, which under the influence of the ultramontane movement of the 19th century had been finally displaced by the rigidly centralized system of the papal monarchy. In this respect it represented a tendency of old standing within the Church and one which, in the 18th century, had all but gained the upper hand (see Ferberianism and Gallicanism). Protestantism takes for its standard the Bible and the supposed doctrines and institutions of the apostolic age. Old Catholicism sets up the authority of the undivided Church, and accepts the decrees of the first seven general councils—down to the second council of Nicaea (787), a principle which has necessarily involved a certain denial of doctrinal divergence both from the standards of Rome and those of the Protestant Churches.

The proceedings of the Vatican council and their outcome had at first threatened to lead to a serious schism in the Church. The minority against the decrees included many of the most distinguished prelates and theologians of the Roman communion, and the methods by which their opposition had been overcome seemed to make it difficult for them to submit. The pressure put upon them was, however, immense, and the reasons for submission may well have seemed overwhelming; in the end, after more or less delay, all the recalcitrant bishops gave in their adhesion to the decrees.

The "sacrificio dell'intelletto," as it was termed—the subordination of individual opinion to the general authority of the Church—was the maxim adopted by one and all. Seventeen of the German bishops almost immediately receded from the position they had taken up at Rome and assented to the dogma, publishing at the same time a pastoral letter in which they sought to justify their change of sentiment on the ground of expediency in relation to the interests of the Church (Michelis, Der neue Fuddar Hirtenbrief, 1870). Their example was followed by all the other bishops of Germany. Darboy, archbishop of Paris, and Dupanloup, bishop of Orleans, in France adopted a like course, and took with them the entire body of the French clergy.

Each bishop demanded in turn the same submission from the clergy of his diocese, the alternative being suspension from pastoral functions, to be followed by deprivation of office. It may be urged as some extenuation of this general abandonment of a great principle, that those who had refused to subscribe to the dogma received but languid support, and in some cases direct discouragement, from their respective governments. The submission of the illustrious Karl Joseph von Hefele was generally attributed to the influence exerted by the court of Württemberg.

The universities, being less directly under the control of the Church, were prepared to show a bolder front. Dr J. F. von Schulze, professor at Prague, was one of the first to publish a formal protest. A meeting of Catholic professors and distinguished scholars convened at Nuremberg (August 1870) recorded a like dissent, and resolved on the adoption of measures for bringing about the assembling of a really free council north of the Alps. The Appel aux Évêques Catholiques de M. Hyacinthe Loyson (better known as "Père Hyacinthe"), after referring to the overthrow of "the two despotisms," "the empire of the Napoleon and the temporal power of the popes," appealed to the Catholic bishops throughout the world to put an end to the schism by declaring whether the recent decrees were or were not binding on the faith of the Church. This appeal, on its appearance in La Liberté early in 1871, was suppressed by the order of the king of Italy. On the 28th of March Döllinger, in a letter of some length, set forth the reasons which compelled him also to withhold his submission alike as "a Christian, a theologian, an historical student and a citizen." The publication of this letter was shortly followed by a sentence of excommunication pronounced against Döllinger and Professor Johannes Friedrich (q.v.), and read to the different congregations from the pulpits of Munich. The professors of the university, on the other hand, had shortly before evinced their resolution of affording Döllinger all the moral support in their power by an address (April 3, 1871) in which they denounced the Vatican decrees with unsparing severity, declaring that, at the very time when the German people had "won for themselves the post of honour on the battlefield among the nations of the earth," the German bishops had stooped to the dishonouring task of "forcing consciences in the service of an unchristian tyranny, of reducing many pious and upright men to distress and want, and of persecuting those who had but stood steadfast in their allegiance to the ancient faith" (Friedberg, Aktenstücke z. ersten Vaticanischen Concil, p. 187). An address to the king, drawn up a few days later, received the signatures of 12,000 Catholics. The refusal of the rites of the Church to one of the signatories, Dr Zenger, when on his deathbed, elicited strong expressions of disapproval; and when, shortly after, it became necessary to fill up a vacancy in the College of Cardinals, through the intervention of the university, the feeling of the electors was indicated by the return of candidates distinguished by their dissent from the new decrees. In the following September the demand for another and a free council was responded to by the assembling of a congress at Munich. It was composed of nearly 300 delegates, convened from almost all parts of the world; but the Teutonic element was now as manifestly predominant as the Latin element had been at Rome. The proceedings were presided over by Professor von Schulte, and lasted three days. Among those who took a prominent part in the deliberations were Landammann Keller, Windscheid, Döllinger, Reinkens, Maassen (professor of canon law at Vienna), Friedrich and Huber. The arrangements finally agreed upon were mainly provisional; but one of the resolutions plainly declared that it was desirable if possible to effect a reunion with the Oriental Greek and Russian Churches, and also to arrive at an "understanding" with the Protestant and Episcopal communions.

In the following year lectures were delivered at Munich by various supporters of the new movement, and the learning and eloquence of Reinkens were displayed with marked effect. In France the adhesion of the abbé Michaud to the cause attracted considerable interest, not only from his reputation as a preacher, but also from the notable step in advance made by his declaration that, inasmuch as the adoption of the standpoint of the Tridentine canons would render reunion with the Lutheran and the Reformed Churches impossible, the wisest course would be to insist on nothing more with respect to doctrinal belief than was embodied in the canons of the first seven oecumenical councils. In the same year the Old Catholics, as they now began to be termed, entered into relations with the historical little Jansenist Church of Utrecht. Döllinger, in delivering his inaugural address as rector of the university of Munich, expressed his conviction that theology had received a fresh impulse and that the religious history of Europe was entering upon a new period.

Other circumstances contributed to invest Old Catholicism with additional importance. It was evident that the relations between the Roman Curia and the Prussian government were becoming extremely strained. In February 1872 appeared the first measures of the Falk ministry, having for their object the control of the influence of the clergy in the schools, and in May the pope refused to accept Cardinal Hohenlohe, who during the council had opposed the definition of the dogma, as Prussian minister at the Vatican. In the same year two humble parish priests, René of Mering in Bavaria and Tangermann of Unkel in the Rhineland, set an example of independence by refusing

1 The rites were administered and the burial service conducted by Friedrich, who had refused to acknowledge his excommunication.
to accept the decrees. The former, driven from his parish church, was followed by the majority of his congregation, who, in spite of every discouragement, continued faithful to him; and for years after the members were removed by death, the crosses over their graves recorded that they had died "true to their ancient belief." Tangermann, the poet, expelled in like manner from his parish by the archbishop of Cologne, before long found himself the minister of a much larger congregation in the episcopal city itself. These examples exercised no little influence, and congregations of Old Catholics were shortly after formed at numerous towns and villages in Bavaria, Baden, Prussia, German Switzerland, and even in Austria. At Warnsdorf in Bohemia a congregation was collected which still represents one of the most important centres of the movement. In September the second congress was held at Cologne. It was attended by some 500 delegates or visitors from all parts of Europe, and the English Church was represented by the bishops of Ely and Lincoln and other distinguished members. At this congress Friedrich boldly declared that the movement was directed "against the whole papal system, a system of errors during a thousand years, which had only reached its climax in the degree of infallibility."

The movement thus entered a new phase, the congress occupying itself mainly with the formation of a more definite organization and with the question of reunion with other Churches. The immediate effect was a fateful divergence of opinion; for many who sympathized with the opposition to the extreme papal claims shrank from the creation of a fresh schism. Prince Chlodwig Hohenlohe, who as prime minister of Bavaria had attempted to unite the governments against the definition of the dogma, refused to have anything to do with proceedings which could only end in the creation of a fresh sect, and would make the prospect of the reform of the Church from within hopeless; more important still, Döllinger refused to take part in setting up a separate organization, and though he afterwards so far modified his opinion as to help the Old Catholic community with sympathy and advice, he never formally joined it.

Meanwhile, the progress of the quarrel between the Prussian government and the Church had been highly favourable to the movement. In May 1873 the celebrated Falk laws were enacted, whereby the articles 15 and 18 of the Prussian constitution were modified, so as to legalize a systematic state supervision over the education of the clergy of all denominations, and also over the appointment and dismissal of all ministers of religion. The measure, which was a direct response to the Vatican decrees, inspired the Old Catholics with a not unreasonable expectation that the moral support of the government would henceforth be enlisted on their side. On the 11th of August Professor J. H. Reinkens of Breslau, having been duly elected bishop of the new community, was consecrated at Rotterdam by Bishop Heykamp of Deventer, the archbishop of Utrecht, who was to have performed the ceremony, having died a few days before. In the meantime the extension of the movement in Switzerland had been proceeding rapidly, and it was resolved to hold the third congress at Constance. The proceedings occupied three days, and it was finally pronounced by chief the institution of a synod as the legislative and executive organ of the Church, and schemes of reunion with the Greek, the African and the Protestant communions. On the 20th of September the election of Bishop Reinkens was formally recognized by the Prussian government, and on the 7th of October he took the oath of allegiance to the king.

The following year (1874) was marked by the assembling of the first synod and a conference at Bonn, and of a congress at Freiburg-im-Breisgau. At the congress Bishop Reinkens spoke in hopeful terms of the results of his observations during a recent missionary tour throughout Germany. The conference, held on the 14th, 15th and 16th of September, had for its special object the discussion of the early confessions as a basis of agreement, though not necessarily of fusion, between the different communions above-named. The meetings, which were presided over by Döllinger, successively took into consideration the Filioque clause in the Nicene creed, the sacraments, the canon of Scripture, the episcopal succession in the English Church, the confessional, indulgences, prayers for the dead, and the eucharist (see DÖLLINGER). The synod (May 27-29) was the first of a series, held yearly till 1879 and afterwards twice a year, in which the doctrine and discipline of the New Church were gradually formulated. The tendency was, naturally, to move further and further away from the Roman model; and though the synod expressly renounced any claim to formulate dogma, or any intention of destroying the unity of the faith, the "Catholic Catechism" adopted by it in 1874 contained several articles fundamentally at variance with the teaching of Rome. At the first synod, too, it was decided to make confession and fasting optional, while later synods pronounced in favour of using the vernacular in public worship, allowing the marriage of priests, and permitting them to administer the communion in both kinds to members of the Anglican Church attending their services. Of these developments that abolishing the compulsory celibacy of the clergy led to the most opposition; some opposed it as inexpedient, others—notably the Jansenist clergy of Holland—as wrong in itself, and when it was ultimately passed in 1878 some of the clergy, notably Tangermann and Reusch, withdrew from the Old Catholic movement.

Meanwhile the movement had made some progress in other countries—in Austria, in Italy and in Mexico; but everywhere it was hampered by the inevitable controversies, which either broke up its organization or hindered its development. In Switzerland, where important conferences were successively convened (at Solothurn in 1871, at Olten in 1872, 1873 and 1874), the conformity of the "Christian Catholics," as they preferred to call themselves, seemed at one time in danger of being shipwrecked on the question of episcopacy. It was not until September 18th, 1876, that the conflict of opinions was so far composed as to allow of the consecration of Bishop Herzog by Bishop Reinkens. The reforms introduced by M. Hyacinthe Loyson in his church at Geneva received only a partial assent from the general body. Among the more practical results of his example is to be reckoned, however, the fact that in French Switzerland nearly all the clergy, in German Switzerland about one half, are married men.

The end of the Kulturkampf in 1878, and the new alliance between Bismarck and Pope Leo XIII. against revolutionary Socialism, deprived the Old Catholics of the special favour which had been shown them by the Prussian government; they continued, however, to enjoy the legal status of Catholics, and their communities retained the rights and the property secured to them by the law of the 4th of July 1875. In Bavaria, on the other hand, the synod of March 1878, though it pronounced the decree definitely reduced to the status of a private religious sect, with very narrow rights. When Bishop Reinkens died in January 1866 his successor Theodor Weber, professor of theology at Breslau, elected bishop on the 4th of March, was recognized only by the governments of Prussia, Baden and Hesse. The present position of the Old Catholic Church has disappointed the expectation of its friends and of its enemies. It has neither advanced rapidly, as the former had hoped, nor retrograded, as the latter have frequently predicted it would do. In Germany there are 90 congregations, served by 60 priests, and the number of adherents is estimated at about 60,000. In Switzerland there are 40 parishes (of which only one, that at Lucerne, is in the
Roman Catholic cantons), 60 clergy and about 50,000 adherents. In Austria, though some accessions have been received since the Los von Rom movement began in 1899, the Old Catholic Church has not made much headway; it has some 15 churches and a few thousand communicants. In the Netherlands the Jansenist Church has 3 bishops, about 35 congregations and over 8000 adherents. In France the movement headed by Loyson did not go far. There is but one congregation, in Paris, where it has for itself a beautiful new church on the Boulevard Blanquin. Its priest is George Volet, who was ordained by Herzog, and it has just over 300 members. It is under the supervision of the Old Catholic archbishops of Utrecht. In Italy a branch of the Old Catholic communion was established in 1881 by Count Enrico di Campello, a former canon of St Peter's at Rome. A church was opened in Rome by Monsignor Savarese and Count Campello, under the supervision of the bishop of Long Island in the United States, who undertook the superintendence of the congregation in accordance with the regulations laid down by the Lambeth conference. But divisions arose between the two men. The church in Rome was closed; Savarese returned to the Roman Church; and Campello commenced a reform work in the rural districts of Umbria, under the episcopal guidance of the bishop of Salisbury. This was in 1885. In 1900 Campello returned to Rome, and once more opened a church there. In 1902 he retired from active participation in the work, on account of age and bodily infirmity; and his place at the head of it was taken by Professor Cicchitti of Milan. The congregation in Rome remains. There are half-a-dozen priests, who are either in Roman Or Old Catholic orders, and about twice as many congregations. Old Catholicism has spread to America. The Polish Romanists there, in 1899, complained of the rule of Irish bishops; elected a bishop of their own, Herr Anton Kozlowski; presented him to the Old Catholic bishops in Europe for consecration; and he presides over seven congregations in Chicago and the neighbourhood. The Austrian and Italian churches possess no bishops, and the Austrian government refuses to allow the Old Catholic bishops of other countries to perform their functions in Austria. Every Old Catholic congregation has its choral union, its poor relief, and its mutual improvement society. Theological faculties exist at Bonn and Bern, and at the former a residential college for theological students was established by Bishop Reinkens. Old Catholicism has eight newspapers—two in Italy, two in Switzerland, and one each in Holland, Germany, Austria and France. It has held reunion conferences at Lucerne in 1892, at Rotterdam in 1894, and at Vienna in 1897. At these, members of the various episcopal bodies have been welcomed. It has also established a quarterly publication, the Revue internationale de théologie, which has been admitted to publication in French, German and English, contributed to by Old Catholics, but by members of the Anglican, Russian, Greek and Slavonic churches. Old Catholic theologians have been very active, and the work of Döllinger and Reusch on the Jesusit, and the history of the Roman Church by Professor Langen, have attained a European reputation.

An outline of the whole movement up to the year 1875 will be found in The New Reformation, by " Theorodus " (J. Bass Mullinger); and an excellent résumé of the main facts in the history of the movement in each European country is to be found in the various developments of liberal thought, and with political history, is given in the second volume of Dr F. Nippich's Handbuch der neuesten Kirchengeschichte, vol. ii. (1885). See also A. M. E. Scarth, The Story of the Church of Christ, and Related Movements (London, 1890); Bühler, Der Altkatholizismus (Leiden, 1880); J. F. von Schulte, Der Altkatholizismus (Giessen, 1887); and articles in Hauck-Herzog's Realencyc. für prot. Theol. und Kirche, i. 415. For details the following books should be consulted: For the history of the Old Catholic movement and its development: the pamphlets of Bishop Reinkens: Rechtsgeschichten über die Frage der Anerkennung des altkatholischen Bischofs Dr Reinkens in Bayern (Munich, 1874); Emil Friedberg, Der Staat und d. Bischofszahlen in Deutschland (Leipzig, 1874); F. von Sybel, Das altkatholische Bisthum und das Vermögen d. römisch-katholischen Kirchengesellschaften in Preussen (Bonn, 1874). (c) Reinkens's own speeches and pastoral letters, some of which have been translated into English, give his personal views and experiences; the Life of Huber has been written and published by Eberhard Sturngiell; and the persecutions to which the Old Catholic clergy were exposed have been set forth in a pamphlet by Mayor, Facts and Documents (London, 1875). OLD DEER, a parish and village in the district of Buchan, Aberdeen, Scotland. Pop. (1901), 4313. The village lies on the Deer or South Ugie Water, 104 m. W. of Peterhead, and 2 m. from Mintlaw station on the Great North of Scotland Railway Company's branch line from Aberdeen to Peterhead. The industries include distilling, brewing, and the manufacture of woollens, and there are quarries of granite and limestone. The town and his nephew Drostan founded a monastery here in the 6th century, of which no trace remains. A most interesting relic of the monks was discovered in 1857 in the Cambridge University library by Henry Bradshaw. It consisted of a small MS. of the Gospels in the Vulgate, fragments of the liturgy of the Celtic church, and notes, in the Gothic script of the 12th century, referring to the charters of the ancient monastery, including a summary of the deeds recorded in these ancient records, among the oldest examples of Scottish Gaelic. The MS. was also adorned with Gaelic designs. It had belonged to the monks of Deer and was in the possession of the University Library since 1715. It was edited by John Stuart (1813-1877) for the Spalding Club, by whom it was published in 1869 under the title of The Book of Deer. In 1528 William Comyn, earl of Buchan, founded the Abbey of St Mary of Deer, now in ruins, 2 m. farther up the river than the monastery and on the opposite bank. Although it was erected for Cistercians from the priory of Kinloss, near Forres, the property of the Columban monastery was removed to it. The founder (d. 1233) and his countess were buried in the church. The parish is rich in antiquities, but the most notable of them—the Stone of Deer, a sculptured block of syenite, which stood near the Abbey—was destroyed in 1854. The thriving village of New Deer (formerly called Auchriddie) lies about 7 m. W. of the older village; it includes the ruined castle of Fedderat.

OLDENBARNEVELDT, JOHAN VAN (1547-1619), Dutch statesman, was born at Amersfoort on the 14th of September 1547. The family from which he claimed descent was of ancient lineage. After studying law at Louvain, Bourges and Heidelberg, and travelling in France and Italy, Oldenbarnevelt settled down to practice at Leuven and at the Hague. In his capacity as a Calvinist, he threw himself with ardour into the revolt against Spanish tyranny and became a zealous adherent of William the Silent. He served as a volunteer for the relief of Haarlem (1573) and again at Leiden (1574). In 1576 he obtained the important post of pensionary of Rotterdam, an office which carried with it the official membership of the States of Holland. In this capacity he conducted the most of affairs, and persuasive powers of speech speedily gained him a position of influence. He was active in promoting the Union of Utrecht (1579) and the acceptance of the constitution of Holland and Zeeland by William (1584) on the assassination of Orange it was at the proposal of Oldenbarnevelt that the youthful Maurice of Nassau was at once elected stadholder, captain-general and admiral of Holland. During the governorship of Leicester he was the leader of the strenuous opposition offered by the States of Holland to the centralized policy of the governor. In 1586 he was appointed, in succession to Paul Buys, to the post of Land's Advocate of Holland. This great office, which he held for 32 years, gave him command of the ability and industry unbounded influence in a many-headed republic without any central executive authority. Though nominally the servant of the States of Holland, he made himself the representative of the provinces which bore more than half the entire charge of the union, and as its mouthpiece in the states-general he practically dominated that assembly. In a brief period he became entrusted with such large and far-reaching authority in all the details of administration, as to be virtually " minister of all affairs."

During the two critical years which followed the withdrawal of Leicester, it was the statesmanship of the advocate which kept the United Provinces from falling asunder through their own inherent separatist tendencies, and prevented them from becoming an easy conquest to the formidable army of Alexander of Parma. Fortunately for the Netherlands the attention of Philip was at their time of greatest weakness riveted upon his contemplated invasion of England, and a respite was afforded which enabled Oldenbarneveldt to supply the lack of any central organized government by gathering into his own hands the control of administrative affairs. His task was made the easier by the whole-hearted support he received from Maurice of Nassau, who, after 1589, held the Stadholderate of five provinces, and was likewise captain-general and admiral of the union. The interests and ambitions of the two men did not clash, for Maurice’s thoughts were centered on the training and leadership of armies and he had no special capacity as a statesman or inclination for politics. The first rift between them came in 1600, when Maurice was forced against his will by the states-general, under the advocate’s influence, to undertake an expedition into Flanders, which was only saved from disaster by desperate efforts which ended in victory at Newgirt. In 1598 Oldenbarneveldt took part in the embassies to Henry IV. and Elizabeth, and again in 1605 in a special mission sent to congratulate James I. on his accession.

The opening of negotiations by Albert and Isabel in 1666 for a peace or long truce led to a great division of opinion in the Netherlands. The archdukes having consented to treat with the United Provinces “as free provinces and states over which they had no pretensions,” Oldenbarneveldt, who had with him the States of Holland and the majority of burgher regents throughout the country, was for peace, provided that liberty of trading was conceded. Maurice and his cousin William Louis, stadholder of Frisia, with the military and naval leaders and the Calvinist clergy, were opposed to it, on the ground that the Spanish king was merely seeking an interval of respite in which to recuperate his strength for a renewed attack on the independence of the Netherlands. For some three years the negotiations went on, but at last after endless parleying, on the 9th of April 1609, a truce for twelve years was concluded. All that the Dutch asked was directly and indubitably granted, and Maurice felt obliged to give a reluctant and somewhat sullen assent to the favourable conditions obtained by the firm and skilful diplomacy of the advocate.

The immediate effect of the truce was a strengthening of Oldenbarneveldt’s influence in the government of the republic, now recognized as a “free and independent state”; external peace, however, was to bring with it internal strife. For some years there had been a war of words between the religious parties, known as the Gomarists (strict Calvinists) and the Arminians (moderate Calvinists). In 1610 the Arminians drew up a petition, known as the Remonstrance, in which they asked that their tenets (defined in five articles) should be submitted to a national synod, summoned by the civil government. It was no secret that this action of the Arminians was taken with the approval and connivance of the advocate, who was what was styled a libertinus, i.e. an Upholder of the principle of toleration in religious opinions. The Gomarists in reply drew up a Contra-Ramonstrance in seven articles, and appealed to a purely church synod. The whole land was henceforth divided into Remonstrants and Contra-Ramonstrants, or the States of Holland, with Oldenbarneveldt supporting the former, and refused to sanction the summoning of a purely church synod (1613). They likewise (1614) forbade the preachers in the Province of Holland to treat of disputed subjects from their pulpits. Obedience was difficult to enforce without military help, riots broke out in certain towns, and when Maurice was appealed to, as captain-general, he declined to act. He did more, though in no sense a theologian; he declared himself on the side of the Contra-Ramonstrants, and established a preacher of that persuasion in a church at the Hague (1617).

The advocate now took a bold step. He proposed that the States of Holland should, on their own authority, as a sovereign province, raise a local force of 4000 men (waard-gelders) to keep the peace. The states-general meanwhile by a bare majority (4 provinces to 3) agreed to the summoning of a national church synod. The States of Holland, also by a narrow majority, refused their assent to this, and passed (August 4, 1617) a strong resolution (Scherpe Resolutie) by which all magistrates, officials and soldiers in the pay of the province were required to take an oath of obedience to the states on pain of dismissal, and were to be held accountable not to the ordinary tribunals, but to the States of Holland. It was a declaration of sovereign independence on the part of Holland, and the states-general took up the challenge and determined on decisive action. A commission was appointed with Maurice at its head to compel the disbanding of the waard-gelders. On the 31st of July 1618 the stadholder appeared at Utrecht, which had thrown in its lot with Holland, at the head of a body of troops, and at his command the local levies at once laid down their arms. His progress through the towns of Holland met with no opposition. The states party was crushed without a blow being struck. On the 23rd of August, by order of the states-general, the advocate and his chief supporters, de Graaf and Hoogerbeets, were arrested. Oldenbarneveldt remained was kept in the strictest confinement until November, and then brought for examination before a commission appointed by the states-general. He appeared more than sixty times before the commissioners and was examined most severely upon the whole course of his official life, and was, most unjustly, allowed neither to consult papers nor to put his defence in writing. On the 20th of February 1619 he was arraigned before a special court of twenty-four members, only half of whom were Hollanders, and nearly all of them his personal enemies. It was in no sense a legal court, nor had it any jurisdiction over the prisoner, but the protest of the advocate, who claimed his right to be tried by the sovereign province of Holland, whose servant he was, was disregarded. He was allowed no advocates, nor the use of documents, pen or paper. It was in fact not a trial at all, and the packed bench of judges on Sunday, the 12th of May, pronounced sentence of death. On the following day the old statesman, at the age of seventy-one, was beheaded in the Binnenhof at the Hague. Such, to use his own words, was his reward for serving his country forty-three years.

The accusations brought against Oldenbarneveldt of having been a traitor to his country, whose interests he had betrayed for foreign gold, have no basis in fact. The whole life of the advocate disproves them, and not a shred of evidence has ever been produced to throw suspicion upon the patriot statesman’s conduct. All his private papers fell into the hands of his foes, but not even the bitterest and ablest of his personal enemies, Francis Aarsens (see AARSENS), could extract from them anything to show that Oldenbarneveldt at any time betrayed his country’s interests. That he was an ambitious man, fond of power, and guilty in his attitude to those who differed from him in opinion, may be granted, but it must also be conceded that he sought power in order to confer invaluable services upon his country, and that impatience of opposition was not unnatural in a man who had exercised an almost supreme control of administrative affairs for upwards of three decades. His high-handed course of action in defence of what he conceived to be the sovereign rights of his own province of Holland to decide religious questions within its borders may be challenged on the grounds of inexpediency, but not of illegality. The harshness of the treatment meted out by Maurice to his father’s old friend, the faithful counsellor and protector of his own early years, leaves a stain upon the stadholder’s memory which can never be washed away. That the prince should have felt compelled in the last resort to take up arms for the Union against the attempt of the province of Holland to defy the authority of the Generality may be justified by the plea reipublicae salus suprema lex. To eject the advocate from power was one thing, to execute him as a traitor quite another. The condemnation of Oldenbarneveldt was carried out with Maurice’s consent and approval, and he
OLDENBURG, a grand-duchy of Germany, with an area of 2479 sq. m. It consists of three widely separated portions of territory—(1) the duchy of Oldenburg, (2) the principality of Lübeck, and (3) the principality of Birkenfeld. It ranks tenth among the states of the German empire and has one vote in the Bundesrat (federal council) and three members in the Reichstag.

The duchy of Oldenburg, comprising fully four-fifths of the entire area and population, lies between 51° 52' and 55° 22' lat. N. and between 7° 34' and 10° 37' long. E., and is bounded on the N. by the North Sea and on the other three sides by Hanover, with the exception of a small strip on the east, where it is conterminous with the territory of the free city of Bremen. It forms part of the north-western German plain lying between the Weser and the Ems, and, except on the south, where the Dammerngebirge attain a height of 478 ft., it is almost entirely flat, with a slight inclination towards the sea. In respect of its soil it is divided broadly into two parts—the higher and inland-lying Geest, consisting of sandy plains intermixed with extensive heaths and moors, and the marsh lands along the coast, consisting of rich but somewhat swampy alluvial soil. The latter, which compose about one-fifth of the duchy, are protected against the inroads of the sea by dikes as in Holland; and beyond these are the so-called Wollen, generally covered at high tide, but at many points being gradually reclaimed. The climate is temperate and humid, the mean temperature of the coldest month at the town of Oldenburg is 38° F., while that of July is 68° F., and their apparent rainfall is more than adequate, and their violence is the more felt owing to the almost entire absence of trees; and fogs and ague are prevalent in the marsh lands. The chief rivers are the Hunte, flowing into the Weser, and the Hase and Leda flowing into the Ems. The Weser itself forms the eastern boundary for 42 m., and internal navigation is greatly facilitated by a canal, passing through the heart of the duchy and connecting the Hunte and the Leda. On the north there are several small coast streams conducted through the dikes by sluices, the only one of importance being the Jade, which empties itself into the Jade Busen, a deep gulf affording good accommodation for shipping. The duchy also contains numerous small lakes, the chief of which is the Dümmer See in the south-east corner, measuring 4 m. in length by 23 m. in width. About 30% of the area of the duchy is under cultivation and 17% under pasture and meadows, while the rest consists mainly of marsh, moor and heath. Forests occupy a very small proportion of the whole, but there are some fine old oaks. In the Geest the principal crops are rye, oats, potatoes and buckwheat, for which the heath is sometimes prepared by burning. Large tracts of moorland, however, are not only producing past for fuel, but are afforested to the flocks of small oaks so well known Oldenburg sheep. The rich soil of the marsh lands produces good crops of wheat, oats, rye, hemp and rape, but is especially adapted for grazing. The cattle and horses raised on it are highly esteemed throughout Germany, and the former are exported in large numbers to England.

Bee-keeping is much in vogue on the moors. The live stock of Oldenburg forms a great part of its wealth, and the ratio of cattle, sheep and horses to the population is one of the highest among the German states. There are few large estates, and the ground is mostly in the hands of small farmers, who enjoy the right of fishing and shooting on their holdings. Game is scarce, but fishing is fairly productive. The mineral wealth of Oldenburg is very small. Woollen and cotton fabrics, stockings, jute and cigars are made at Varel, Delmenhorst and Löhne; cork-cutting is extensively practised in some districts, and there are a few iron-foundries. Trade is relatively of more importance, chiefly owing to the proximity of Bremen. The agricultural produce of the duchy is exported to Scandinavia, Russia, England and the United States, in return for colonial goods and manufactures.

Varel, Brake and Elsfleth are the chief commercial harbours.

II. The principality of Lübeck has an area of 200 sq. m. and shares in the general physical characteristics of east Holstein, within which it lies. On the east it extends to Lübeck Bay of the Baltic Sea, and on the south-east it is bounded by the Trave. The chief rivers are the Schwartau, a tributary of the Trave, and the Schwentine, flowing northwards to the Gulf of Kiel. The scenery of Lübeck is often picturesque, especially in the vicinity of the Plön See and the Eutin See, the most important of the small lakes with which it is dotted. Agriculture is practised here even more extensively than in the duchy of Oldenburg, although 75% of the area being cultivated. The population in 1905 was 28,396.

III. The principality of Birkenfeld, 312 sq. m. in extent, lies in the midst of the Prussian province of the Rhine, about 30 m. W. of the Rhine at Worms and 150 m. S. of the duchy of Oldenburg. The population in 1905 was 46,484. (See Birkenfeld.)

The total population of the grand-duchy of Oldenburg in 1880 was 337,478, and in 1905 438,866. The bulk of the inhabitants are of the Saxon stock, but to the north and west of the duchy there are numerous descendants of the ancient Frisians. The differences between the two races are still so to some extent perceptible, but Low German (Platt-deutsch) is universally spoken, except in one limited district, where a Frisian dialect has maintained itself. In general characteristics the Oldenburg peasants resemble the Dutch, and the absence of large landowners has contributed to make them sturdy and independent. The population of Oldenburg is somewhat unequally distributed, some parts of the marsh lands containing over 300 persons to the square mile, while in the Geest the number occasionally sinks as low as 40. About 70% of the inhabitants belong to the "rural" population. The town of Oldenburg is the capital of the grand-duchy. The port of Wilhelmshaven on the Jade Busen, was built by Prussia on land bought from Oldenburg. The chief towns of Birkenfeld and Lübeck respectively are Birkenfeld and Eutin.

Oldenburg is a Protestant country, and the grand-duke is required to be a member of the Lutheran Church. Roman Catholicism, however, preponderates in the south-western provinces, which formerly belonged to the bishopric of Münster. Oldenburg Roman Catholics are under the sway of the bishops of Münster, who is represented by an official at Vechta. The educational system of Oldenburg is on a similar footing to that of north Germany in general, though the scattered position of the farmhouses interferes to some extent with school attendance.

The constitution of Oldenburg, based upon a decree of 1849, revised in 1852, is one of the most liberal in Germany. It provides for a single representative chamber (Landtag), elected indirectly by universal suffrage and exercising concurrent rights of legislation and taxation with the grand-duke. The chamber which consists of forty members, one for every 25,000 inhabitants is elected every three years. The executive consists of three ministers, who are aided by a committee of the Landtag, when that body is not in session. The local affairs of Birkenfeld and Lübeck are entrusted to provincial councils of fifteen members each. All citizens paying taxes and not having been convicted of felony are enfranchised. The municipal communities enjoy an unusual amount of independence. The finances of each constituent state of the grand-duchy are managed separately, and there is also a fourth budget concerned with the joint
oldenburg

administration. The total revenue and expenditure are each about $60,000 annually. The grand-duchy had a debt in 1507 of £5,958,400.

History. — The earliest recorded inhabitants of the district now called Oldenburg were a Teutonic people, the Chauci, who were afterwards merged in the Frisians. The chroniclers delight in tracing the genealogy of the counts of Oldenburg to the Saxon hero, Widukind, the stubborn opponent of Charlemagne, but their first historical representative is one Elimar (d. 1108) who is described as "comes in confinis Saxoniae et Frisiae." Elimar's descendants appear as vassals, although sometimes rebellious ones, of the dukes of Saxony; but they attained the dignity of princes of the empire when the emperor Frederick I. dismembered the Saxon duchy in 1180. At this time the county of Delmenhorst formed part of the dominions of the counts of Oldenburg, but afterwards it was on several occasions separated from them to form an apanage for younger branches of the family. This was the case between 1262 and 1447, between 1463 and 1547, and between 1577 and 1617. The northern and western parts of the present grand-duchy of Oldenburg were in the hands of independent, or semi-independent, Frisian princes, who were usually heathens, and during the early part of the 13th century the counts carried on a series of wars with these small potentates which resulted in a gradual expansion of their territory. The freedom of Schleswig and the bishopric of Münster were frequently at war with the counts of Oldenburg.

The successor of Count Dietrich (d. 1440), called Fortunatus, was his son Christian, who in 1448 was chosen king of Denmark as Christian I. In 1450 he became king of Norway and in 1457 king of Sweden; in 1460 he inherited the duchy of Schleswig and the county of Holstein, an event of high importance for the future history of Oldenburg. In 1454 he handed over Oldenburg to his brother Gerhard (c. 1430-1499) a turbulent prince, who was constantly at war with the bishop of Bremen and other neighbours. In 1483 Gerhard was compelled to abdicate in favour of his sons, and he died whilst on a pilgrimage in Spain. Early in the 16th century Oldenburg was again enlarged at the expense of the Frisians. Protestantism was introduced into the county by Count Anton I. (1505-1573), who also suppressed the monasteries; however, he remained loyal to Charles V. during the war of the league of Schmalkalden, and was able thus to increase his territories, obtaining Delmenhorst in 1547. One of Anton's brothers, Count Christopher (c. 1506-1560), won some reputation as a soldier. Anton's grandson, Anton Günther (1583-1667), who succeeded in 1603, gave up the ancient claims of his forefathers to the grand-duchy of Oldenburg. He never had acquired before he became count, but in 1624 he added Knophausen and Avelen to his lands, with which in 1647 Delmenhorst was finally united. By his prudent neutrality during the Thirty Years' War Anton Günther secured for his dominions an immunity from the terrible devastations to which nearly all the other states of Germany were exposed. He also obtained from the emperor the right to levy tolls on vessels passing along the Weser, a lucrative grant which soon formed a material addition to his resources.

When Count Anton Günther died in June 1667 Oldenburg was inherited by virtue of a compact made in 1649 by Frederick III., king of Denmark, and Christian Albert, duke of Holstein-Gottorp. Some difficulties, however, arose from this joint ownership, but eventually these were satisfactorily settled, and from 1702 to 1773 the county was ruled by the kings of Denmark only, this period being on the whole one of peaceful development. Then in 1773 another change took place. Christian VII. of Denmark surrendered Oldenburg to Paul, duke of Holstein-Gottorp, afterwards the emperor Paul of Russia, and in return Paul gave up to Christian his duchy of Holstein-Gottorp and his claims on the duchies of Schleswig and Holstein. At once Paul handed over Oldenburg to his kinsman, Frederick Augustus, bishop of Lübeck, the representative of a younger branch of the family, and in 1777 the county was raised to the rank of a duchy. The bishop's son William, who succeeded his father as duke in 1755, was a man of weak intellect, and his cousin Peter Frederick, bishop of Lübeck, acted as administrator and eventually, in 1823, inherited the duchy. This prince is the direct ancestor of the present grand duke.

To Peter fell the onerous task of governing the duchy during the time of the Napoleonic wars. In 1806 Oldenburg was occupied by the French and the Dutch, the duke and the regent being put to flight; but in 1807 William was restored, and in 1808 he joined the Confederation of the Rhine. However, in 1810 his lands were forcibly seized by Napoleon because he refused to exchange them for Erfurt. This drove him to join the Allies, and at the congress of Vienna his services were rewarded by the grant of the principality of Birkenfeld, an addition to his lands due to the good offices of the tsar Alexander I. At this time Oldenburg was made a grand duchy, but the title of grand-duke was not formally assumed until 1829, when Augustus succeeded his father Peter as ruler. Under Peter's rule the area of Oldenburg had been increased, not only by Birkenfeld, but by the bishopric of Lübeck (secularized in 1802) and some smaller pieces of territory.

Oldenburg did not entirely escape from the revolutionary movement which swept across Europe in 1848, but no serious disturbances took place, and the duchy united itself to the Nizhniye Novgorod. The duchy of Oldenburg is a constitutional monarchy, and its government is in the hands of the grand-duke.

Oldenburg's history is closely connected with that of Holstein-Sonderburg. It was first ruled by the house of Oldenburg, and in 1815 it became a part of the kingdom of Hanover. In 1866 it was united with Hanover and joined the North German Confederation; in 1871 Oldenburg became a state of the new German empire. In June 1900 Christopher Augustus II. (b. 1852) succeeded his father Peter as grand-duek. By a law passed in 1904 the succession to Oldenburg was vested in the grand-duke Christian I., who succeeded his father in 1905.

See also *The Jahresbuch für Geschichte des Herzogtums Oldenburg* (1892 seq.).

OLDENBURG, a town of Germany, and capital of the grand-duchy of Oldenburg. It is a quiet and pleasant-looking town, situated 27 m. by rail W. of Bremen, on the navigable Hunte and the Hunte-Ems canal. Pop. (1905), including the suburbs, 28,555. The inner or old town, with its somewhat narrow streets, is surrounded by avenues laid out on the site of the former ramparts, beyond which are the villas, promenades and gardens of the modern quarters. Oldenburg has almost nothing to show in the shape of interesting old buildings. The

1 His father, Charles Frederick of Holstein-Gottorp (1700-1739), a descendant of Christian I. of Denmark, married Anne, daughter of Peter the Great, and became tsar as Peter III. in 1762.

1 To this branch belonged Adolphus Frederick, son of Christian Augustus bishop of Lübeck (d. 1726), who in 1751 became king of Sweden.

Another branch of the Oldenburg family, descended from John, son of Christian III. of Denmark, is that of Holstein-Sonderburg. This was subdivided into the lines of Sonderburg-Augustenburg and Sonderburg-Glücksburg. Prince Christian, who married Princess Helena of Great Britain, belongs to the former of them. To the latter belong the kings of Denmark, Greece and Norway.
OLDFIELD—OLDHAM, T.

Evangelical Lambertikirche, though dating from the 13th century, has been so transformed in the last century (1874–1886) as to show no trace of its antiquity. The palaces of the grand-duke and the old town-hall are Renaissance buildings of the 17th and 18th centuries. Among the other prominent buildings—all modern—are the palace of the heir apparent, the new town-hall, the theatre, the law-courts, the gymnasium, the commercial school, the three hospitals and the new Roman Catholic church. The grand-ducal picture gallery in the Augusteum includes works by Veronese, Velasquez, Murillo and Rubens, and there are collections of modern paintings and sculptures in the two palaces. The public library contains 110,000 volumes and the duke's private library 55,000. There is also a large natural history museum and a museum with a collection of antiquities. The industries of Oldenburg, which are of no great importance, include iron-founding, spinning and the making of glass, tobacco, gloves, soap and leather. A considerable trade is carried on in grain, and the horse fairs are largely frequented. According to popular tradition Oldenburg was founded by Walbert, grandson of the Saxon hero, Widukind, and was named after his wife Altburga, but the first historical mention of it occurs in a document of 1108. It was fortified in 1155, and received a municipal charter in 1345. The subsequent history of the town is merged in that of the grand-duchy.

See Sello, Historische Wanderung durch die Stadt Oldenburg (Oldenburg, 1896); and Alt-Oldenburg (Oldenburg, 1903); and Kohl, Die Alte Zeit der Stadt Oldenburg (Oldenburg, 1903).

OLDFIELD, ANNE (1683–1730), English actress, was born in London, the daughter of a soldier. She worked for a time as apprentice to a sempstress, until she attracted George Farquhar's attention by reciting some lines from a play in his hearing. She thereupon obtained an engagement at Drury Lane, where her beauty rather than her ability slowly brought her into favour, and it was not until ten years later that she was generally acknowledged as the best actress of her time. In polite comedy, especially, she was unrivalled, and even the usually grudging Cibber acknowledged that she had as much as he to do with the success of the Careless Husband (1704), in which she created the part of Lady Modish, reluctantly given her because Mrs. Brerburgen was ill. In tragedy, too, she won laurels, and the list of her parts, many of them original, is a long and varied one. She was the theatrical idol of her day. Her exquisite acting and lady-like carriage were the delight of her contemporaries, and her beauty and generosity found innumerable eulogists, as well as sneering detractors. Alexander Pope, in his Sober Advice from Horace, wrote of her—

"Engaging Oldfield, who, with grace and ease, Could join the arts to ruin and to please.

It was to her that the satirist alluded as the lady who detested being buried in woollen, who said to her maid—

"No, let a charming chintz and Brussels lace Wrap my cold limbs and shade my lifeless face; One would not be sure, be frightful when one's dead, And—Betty—give this cheek a little red."

She was but forty-seven when she died on the 23rd of October 1730, leaving all the court and half the town in tears. She divided her property, for that time a large one, between her natural sons, the first by Arthur Mainwaring (1668–1712)—who had left her and his son half his fortune on his death—and the second by Lieut.-General Charles Churchill (d. 1745). Mrs Oldfield was buried in Westminster Abbey, beneath the monument to Congreve, but when Churchill applied for permission to erect a monument there to her memory the dean of Westminster refused it.

OLD FORGE, a borough of Lackawanna county, Pennsylvania, U.S.A., on the Lackawanna river, about 6 m. S.W. of Scranton. Pop. (1900) 5630 (2494 foreign-born, principally Italians); (1910) 11,324. It is served by the Delaware, Lackawanna & Western and the Lehigh Valley railways. The principal public buildings are the town-hall and the high school. The borough is situated in the anthracite coal region, and the mining of coal is the principal industry, though there are also various manufactures.

Old Forge was settled in 1830 and incorporated as a borough in 1835.

OLDHAM, JOHN (1663–1683), English satirist, son of a Presbyterian minister, was born at Shipton Morey, near Tetherbury, Gloucestershire, on the 9th of August 1653. He graduated from St Edmund Hall, Oxford, in 1674, and was for three years an usher in a school at Croydon. Some of his verses attracted the attention of the town, and the earl of Rochester, with Sir Charles Sedley and other wits, came down to see him. The visit did not affect his career apparently, for he stayed at Croydon until 1681, when he became tutor to the grandsons of Sir Edward Thurland, near Reigate. Meanwhile he had tried, he says, to conquer his inclination for the unprofitable trade of poetry, but in the panic caused by the revelations of Titus Oates, he found an opportunity for the exercise of his gift for rough satire. Garnet's Ghost was published as a broadside in 1679, but the other Satires on the Jesuits, although written at the same time, were not printed until 1681. The success of these dramatic and unsparing invectives apparently gave Oldham hope that he might become independent of teaching. But his undoubted services to the Country Party brought no reward from its leaders. He became tutor to the son of Sir William Hickes, and was eventually glad to accept the patronage of William Pierrepont, earl of Kingston, whose kindly offer of a chancery he had refused earlier. He died at Holme-Pierpoint, near Nottingham, on the 9th of December 1683, of smallpox.

Oldham took Juvenal for his model, and in breadth of treatment and power of inventive surpassed his English predecessors. He was original in the dramatic setting provided for his satires. Thomas Garnet, who suffered for supposed implication in the Gunpowder Plot, rose from the dead to encourage the Jesuits in the first satire, and in the third Ignatius Loyola is represented as dictating his wishes to his disciples from his death-bed. Oldham wrote other satires, notably one "addressed to a friend about to leave the university," which contains a well-known description of the state of slavery of the private chaplain, and another "dissuading from poetry," describing the ingratitude shown to Edmund Spenser, whose ghost is the speaker, to Samuel Butler and to Abraham Cowley. Oldham's verse is rugged, and his rhymes often defective, but he met with a generous appreciation from Dryden, whose own satiric bent was perhaps influenced by his efforts. He says ("To the Memory of Mr Oldham," Works, ed. Scott, vol. xi. p. 96)—

"For sure our souls were near allied, and thine Cast in the same poetic mould with mine."

The real wit and rigour of Oldham's satirical poetry are undeniable, while its faults—its frenzied extravagance and lack of metrical polish—might, as Dryden suggests, have been cured with time, for Oldham was only thirty when he died.

The best edition of his works is The Compositions in Prose and Verse of Mr John Oldham . . . (1770), with memoir and explanatory notes by Edward Thompson.

OLDHAM, THOMAS (1816–1878) British geologist, was born in Dublin on the 4th of May 1816. He was educated there at Trinity College, graduating B.A. in 1836, and afterwards studied engineering in Edinburgh, where he gained a good knowledge of geology and mineralogy under Jameson. On his return to Ireland in 1839 he became chief assistant to Captain (afterwards Major General) Portlock, who conducted the geological department of the Ordnance Survey, and he rendered much help in the field and office in the preparation of the Report on the Geology of Londonderry, &c. (1843). Subsequently he served under Captain (afterwards Sir Henry) James, the first local director of the Geological Survey of Ireland, whom he succeeded in 1846. Meanwhile in 1843 he was appointed professor of Geology in the university of Dublin. In 1848 he was elected F.R.S. In 1849 he discovered in the Cambrian rocks of Bray Head the problematical fossil named Oldhamia. In 1850 he was selected to take charge of the Geological Survey of India, which he organized, and in due course he established the Memoirs, the Palaeontologia Indica and the Records, to which he contributed
OLDHAM—OLD TOWN

many important articles. In 1864 he published an elaborate report On the Coal Resources of India. He retired in 1876, and died at Rugby on the 7th of July 1878.

OLDHAM, a municipal county and parliamentary borough of Lancashire, England, 7 m. N.E. of Manchester, on the London & North-Western, Great Central and Lancashire & Yorkshire railways and the Oldham canal. Pop. (1891) 131,463; (1901) 137,246. The principal railway station is called Mumps, but there are several others. The town lies high, near the source of the small river Medlock. Its growth as a manufacturing centre gives it a wholly modern appearance. Among several handsome churches the oldest dates only from the later 18th century. The principal buildings and institutions include the town-hall, with tetrastyle portico copied from the Ionic temple of Ceres near Athens, the reference library, art gallery and museum, the Union Street baths, commemorating Sir Robert Peel the statesman, and the county court. Of educational establishments the chief are the Lyceum, a building in Italian style, containing schools of art and science, and including an observatory; the largely-endowed blue-coat school founded in 1808 by Thomas Henshaw, a wealthy manufacturer of hats; the Hulme grammar school (1865), and municipal technical schools. The Alexandra Park, opened in 1865, was laid out by operators who were thrown out of employment owing to the cotton famine in the years previous to that date. The site is picturesquely undulating and terraced. Oldham is one of the most important centres of the cotton manufactures, the consumption of cotton being about one-fifth of the total importation into the United Kingdom, the factories numbering some 250, and the spindles over 13 millions, while some 35,000 operatives are employed. The principal manufactures are fustians, velvets, cords, shirtings, sheetings and nankeens. There are also large foundries and mill and cotton machinery works; and works for the construction of gas-meters and sewing-machines; while all these industries are assisted by the immediate presence of collieries. There are extensive markets and numerous fairs are held. Oldham was incorporated in 1849, and became a county borough in 1888. The corporation consists of a mayor, 12 aldermen and 36 councillors. The parliamentary borough has returned two members since 1832. Area of municipal borough, 4736 acres.

A Roman road, of which some traces are still left, passes through the site of the township. It does not appear to have been a Roman station. It is not mentioned in Domesday; but in the reign of Henry III. Alwardus de Aldiholme is referred to as holding land in Vernet (Werneth). A daughter and co-heiress of this Alwardus conveyed Werneth Hall and its manor to the Cudworths, a branch of the Yorkshire family, with whom it remained till the early part of the 18th century. From the Oldhams was descended Hugh Oldham, who died bishop of Exeter in 1510. From entries in the church registers it would appear that linen was manufactured in Oldham as early as 1630. Watermills were introduced in 1770, and with the adoption of Arkwright's inventions the cotton industry grew with great rapidity.

OLD MAID, a game of cards. Any number may play, and the full pack is used, the Queen of Hearts being removed. The cards are dealt out one by one until exhausted, and each player then sorts his hand and discards the pairs. The dealer then offers his hand, spread out face downwards to the next player, who draws a card, which, if it completes a pair, is discarded, but otherwise remains in the township. It does not appear to have been a Roman station. It is not mentioned in Domesday; but in the reign of Henry III. Alwardus de Aldiholme is referred to as holding land in Vernet (Werneth). A daughter and co-heiress of this Alwardus conveyed Werneth Hall and its manor to the Cudworths, a branch of the Yorkshire family, with whom it remained till the early part of the 18th century. From the Oldhams was descended Hugh Oldham, who died bishop of Exeter in 1510. From entries in the church registers it would appear that linen was manufactured in Oldham as early as 1630. Watermills were introduced in 1770, and with the adoption of Arkwright's inventions the cotton industry grew with great rapidity.

OLDMIXON, JOHN (1673-1742), English historian, was a son of John Oldmixon of Oldmixon, near Bridgewater. His first writings were poems and dramas, among them being Amores Britannici; Epistles historical and gallant (1703); and a tragedy, The Governor of Cyprus. His earliest historical work was The British Empire in America (1708 and again 1741), which was followed by The Secret History of Europe (1712-1715); by Arcaea Gallica, or the Secret History of France for the last Century (1714); and by other smaller writings. More important, however, although of a very partisan character, are Oldmixon's works on English History. His Critical history of England (1724-1726) contains attacks on Clarendon and a defence of Bishop Burnet, and its publication led to a controversy between Dr Zachary Grey (1688-1766) and the author, who replied to Grey in his Clarendon and Whillock compared (1727). On the same lines he wrote his History of England during the Reigns of the Royal House of Stuart (1730). Herein he charged Bishop Atterbury and other of Clarendon's editors with tampering with the text of the History. From his exile Atterbury replied to this charge in a Vindication, and although Oldmixon continued the controversy it is practically certain that he was in the wrong. He completed a continuous history of England by writing the History of England during the Reigns of William and Mary, Anne and George I. (1735); and the History of England during the Reigns of Henry VIII., Edward VI., Mary and Elizabeth (1739). Among his other writings are, Memoirs of North Britain (1715), Essay on Criticism (1728) and Memoirs of the Press 1710-1730 (1743), which was only published after his death. Oldmixon had much to do with editing two periodicals, The Muses Mercury and The Medley, and he often complained that it was not allowed to overlook the errors of speech made in the 6th of July 1742.

OLD POINT COMFORT, a summer and winter resort, in Elizabeth City county, Virginia, U.S.A., at the southern end of a narrow, sandy peninsula projecting into Hampton Roads (at the mouth of the James river), about 12 m. N. by W. of Norfolk. It is served directly by the Chesapeake & Ohio railway, and indirectly by the New York, Philadelphia & Norfolk (Pennsylvania System), passengers and freight being carried by steamer from the terminus at Cape Charles; by steamboats and steamer lines connecting with the principal cities along the Atlantic coast, and with cities along the James river; by ferry, connecting with Norfolk and Portsmouth; and by electric railway (3 m.) to Hampton and (12 m.) to Newport News. There is a U.S. garrison at Fort Monroe, one of the most important fortifications on the Atlantic coast of the United States. Old Point Comfort is included in the reservation of Fort Monroe. The fort lies within the tract of 252 acres ceded, for coast defence purposes, to the Federal government by the state of Virginia in 1821, the survey for the original fortifications having been made in 1824, and the buildings completed in 1841. Old Point Comfort was first regularly garrisoned in 1823; in 1824 the Artillery School of Practice (now called the United States Coast Artillery School) was established to provide commissioned officers of the Coast Artillery with instruction in professional work and to give technical instruction to the non-commissioned staff. During the Civil War the fort was the rendezvous for several military expeditions, notably those of General Benjamin F. Butler to Hatteras Inlet, in 1861; of General A. E. Burnside, to North Carolina, in 1862; and of General A. H. Terry, against Fort Fisher, in 1865; within sight of its parapets was fought the famous duel between the “Monitor” and the “Merrimac” (March 9, 1862). Jefferson Davis was a prisoner here for two years, from the 22nd of May 1865, and Clement Claiborne Clay (1819-1883), a prominent Confederate, from the same date until April 1866. Between Fort Monroe and Sewell's Point is Fort Wool, almost covering a small island called Rip Raps. The expedition which settled Jamestown rounded this peninsula (April 26, 1607), opened its scaled instructions here, and named the bay after James, son of Henry, prince of Wales. In the position of the sheltered harbour. (The “Old” was added subsequently to distinguish it from a Point Comfort settlement at the mouth of the York river on Chesapeake Bay). On the site of the present fortification a fort was erected by the whites as early as 1630.

OLD TOWN, a city of Penobscot county, Maine, U.S.A., on the Penobscot river, about 12 m. N.E. of Bangor. Pop. (1890) 5312; (1900) 5763 (1247 foreign-born); (1910) 6317. It is served by the Maine Central and the Bangor & Aroostook railways, and by an electric line connecting with Bangor. The city proper is on an island (Marsh, or Old Town Island), but considerable territory on the W. bank of the river is included.
within the municipal limits. The manufacture of lumber is the principal industry of the city. On Indian Island (opposite the city) is the principal settlement of the Penobscot Indians, an Abnaki tribe, now wards of the state. The Abbé Louis Pierre Thury was sent here from Quebec about 1687 and built a church in 1688-1689; in 1705 the mission passed under the control of the Jesuits. The first white settler in the vicinity seems to have been John Marsh, who came about 1774, and who bought the island now known as Marsh Island. From 1806 to 1840, when it was incorporated as a separate township, Old Town was a part of Orono. In 1891 it was chartered as a city. One of the oldest railroads in the United States, and the first in Maine, was completed to Old Town from Bangor in 1836.

OLDYS, WILLIAM (1666-1761), English antiquary and bibliographer, natural son of Dr William Oldys, chancellor of Lincoln, was born on the 14th of July 1666, probably in London. His father had also held the office of advocate of the admiralty, but lost it in 1693 because he would not prosecute as traitors and pirates the sailors who had served against England under James II. William Oldys, the younger, lost part of his small patrimony in the South Sea Bubble, and in 1724 went to Yorkshire, spending the greater part of the next six years as the guest of the earl of Malton. On his return to London he found that his landlord had disposed of the books and papers left in his charge. Among these was an annotated copy of Gerard Langbaine's Drameick Poets. The book came into the hands of Thomas Coxeter (1689-1747), and subsequently into Theophilus Cibber's possession, and furnished the basis of the Lives of the Poets (1735) published with Cibber's name on the title-page, though most of it was written by Robert Shiels. In 1737 Oldys sold his collections to Edward Harley, second earl of Oxford, who appointed him his literary secretary in 1738. Three years later his patron died, and from that time he worked for the booksellers. His habits were irregular, and in 1751 his debts drove him to the Fleet prison. After two years' imprisonment he was released through the kindness of friends who paid his debts, and in April 1755 he was appointed Norroy king-at-arms by the duke of Norfolk. He died on the 15th of April 1761.

Oldys's chief works are: The British Librarian, a review of scarce and valuable books in print and in manuscript (1737-1738); the Harleian Miscellany (1744-1746), a collection of tracts and pamphlets in the earl of Oxford's library, undertaken in conjunction with Dr Johnson; twenty-two editions of the Italian poet Tasso; and the Bibliotheca Britannica; an edition of Ralph's History of the World, with a Life of the author (1736); Life of Charles Cotton prefixed to Sir John Hawkins's edition (1760) of the Compleat Angler. In 1727 Oldys began to annotate another Langbaine to replace the one he had lost. This valuable book, with a MS collection of notes by Oldys on various bibliographical subjects, is preserved in the British Museum.

OLEAN, a city of Cattaraugus county, in south-western New York, U.S.A., on Olea Creek and the N. side of the Allegheny river, 70 m. S.E. of Buffalo. Pop. (1880), 3036; (1890), 7358; (1900), 9426, of whom 1514 were foreign-born and 122 were negroes; (1910 census), 14,743. The city is served by the Erie, the Pittsburg, Shawmut & Northern, and the New York railways (the last has large car shops here); and is connected with Bradford, Pa., Allegany, Pa., Salamanca, N.Y., Little Valley, N.Y., and Bolivar, N.Y., by electric lines. Olean is situated in a level valley 1440 ft. above sea-level. The surrounding country is rich in oil and natural gas. Six miles from Olean and 2000 ft. above the sea-level is Rock City, a group of immense, strangely regular, conglomerate rocks (some of them pure white) covering about 40 acres. They are remnants of a bed of Upper Devonian Conglomerate, which broke along the joint planes, leaving a group of huge blocks. In the city are a public library, a general hospital and a state asylum; and at Allegany (pop. 1910, 1286), about 3 m. W. of Olean, is St Bonaventure's College (1859; Roman Catholic). Olean's factory yard was valued at $4,077,477 in 1905; the city is the terminus of an Ohio pipe line, and of a sea-board pipe line for petroleum; and among its industries are oil-refining and the refining of wood alcohol, tanning, currying, and finishing leather; and the manufacture of flour, glass (mostly bottles), lumber, &c. The vicinity was settled in 1804, and it was the first township organized (1806), being then coextensive with the county. Olean Creek was called Ischue (or Ischa); then Olean was suggested, possibly in reference to the oil-springs in the vicinity. The village was officially called Hamilton for a time, but Olean was the name given to the post-office in 1817, and Olean Point was the popular local name. In 1909 several suburbs, including the village of North Olean (pop. in 1905, 1761), were annexed to Olean, considerably increasing its area and population.

OLEANDER, the common name for the shrub known to botanists as Nerium oleander. It is a native of the Mediterranean and Levant, and is characterized by its tall shrubby habit and its thick lance-shaped opposite leaves, which exude a milky juice when punctured. The flowers are borne in terminal clusters, and are like those of the common periwinkle (Vinca), but are of a rose colour, rarely white, and the throat or upper edge of the tube of the corolla is occupied by outgrowths in the form of lobed and fringed petal-like scales. The hairy anthers adhere to the thickened stigmas. The fruit or seed-vessel consists of elongated long pods, which, bursting along one edge, liberate a number of seeds, each of which has a tuft of silky hairs like thistle down at the upper end. The genus belongs to the natural order Apocynaceae, a family that, as is usual where the milk juice is abundant, is marked by its poisonous properties. Cases are recorded by Lindley of children poisoned by the flowers. The same author also narrates how in the course of the Peninsular War some French soldiers died in consequence of employing skewers made from freshly-cut twigs of oleander for roasting their meat. The oleander was known to the Greeks under three names, viz. rhododendron, nerium and rhododaphne, and is well described by Pliny (xvi. 20), who mentions its rose-like flowers and poisonous qualities, at the same time stating that it was considered serviceable as a remedy against snake-bite. The name is supposed to be a corruption of lorandrum, lauridendrum (Du Cange), influenced by olea, the olive-tree, lorandrum being itself a corruption of rhododendron. The modern Greeks still know the plant as podolphoin, although in a figure in the Rinuccini MSS. of Dioscorides a plant is represented under this name, which, however, had rather the appearance of a willow herb (Epilobium). The oleander has long been cultivated in greenhouses in England, being, as Gerard says, "a small shrub of a gallant shewe"; numerous varieties, differing in the colour of their flowers, which are often double, have been introduced.

OLEASTER, known botanically as Elaeagnus hortensis, a handsome deciduous shrub, 15 to 25 ft. high, growing in the Mediterranean region and temperate Asia, where it is commonly cultivated for its edible fruit. The brown smooth branches are more or less spiny; the narrow leaves have a hoary look from the presence of a dense covering of star-shaped hairs; the small fragrant yellow flowers, which are borne in the axils of the leaves, are scaly on the outside. The genus contains other species of ornamental deciduous or evergreen shrubs or small trees. E. argentea, a native of North America, has leaves and fruit covered with shining silvery scales. In E. glabra, from Japan, the evergreen leaves are clothed beneath with rust-coloured scales; variegated forms of this are cultivated, as also of E. pungens, another Japanese species, a spiny shrub with leaves silvery beneath.
OLEFIN—OLEG

OLEFINE. in organic chemistry, the generic name given to open chain hydrocarbons having only singly and doubly linked pairs of carbon atoms. The word is derived from the French olefine (from olefier, to make oil), which was the name given to ethylene, the first member of the series, by the Dutch chemists, J. R. Deiman, Paets van Troostwyk, N. Bondt and A. Lauverenburg in 1795. The simple olefines containing one doubly-linked pair of carbon atoms have the general formula (C₄H₈); the diols, containing two doubly-linked pairs, have the general formula C₆H₁₀ and are consequently isomeric with the simple acetylenes. Tri-, tetra- and more complicated members are also known. The name of any particular member of the series is derived from that of the corresponding member of the paraffin series by removing the final syllable "ane," and replacing it by the syllable "ylene." Isomerism in the olefine series does not appear until the third member of the series is reached.

The higher olefines are found in the tar which is obtained by distilling bituminous shales, in illuminating gas, and among the products formed by distilling paraffin under pressure (T. E. Thorpe and J. Young, Ann., 1873, 165, p. 1). The olefines may be synthetically prepared by eliminating water from ethyl alcohol and on heating the halides with phosphorus. Products linked with the halogens and eventually with metals form the halides of ethylene, ethane, propylene and ethylene halides by reducing them (Cl→MCl). Examples include ethylene in nickel, which may be prepared by the condensation of ethylene naphtalene with sodium or iron (J. Schmidt, Ber., 1905, 38, p. 2415). They combine with nitrosyl bromide and chloride, and with many metallic haloid salts (platinum bichloride, iodide chloride), with mercury salts (see K. A. Hofmann and J. Sand, Ber., 1900, 33, p. 1340 et seq.), and those with a tertiary carbon atom yield double salts with zinc chloride.

In chemical properties, however, they differ very markedly from the paraffins. As unsaturated compounds they can combine with two monovalent atoms. Hydrogen is absorbed readily at ordinary temperature in the presence of platinum black, and paraffins are formed; the halogens (chlorine and bromine) combine directly with them, giving dihalogen substituted compounds; the halogen halides form monohalogen derivatives (hydride acid reacts most readily, hydrochloric acid, least); and it is to be noted that the haloid acids attach themselves in such a manner that the halogen atom unites itself to the carbon atom which is in combination with the fewest hydrogen atoms (W. Markownikoff, Ann., 1870, 153, p. 256).

They combine with hypochlorous acid to form chlorhydrins, and are easily soluble in concentrated sulphuric acid, giving rise to solutions of the corresponding acids. They are also easily reduced by alcohol solutions of the acid, from which they are boiled with water, the alcohol from which the olefine was in the first place derived is regenerated. The oxides of nitrogen convert them into nitriles and nitrosoes (O. Wallach, Ann., 1887, 241, p. 288, &c.; J. Schmidt, Ber., 1905, 38, p. 2415). They combine with nitrosyl bromide and chloride, and with many metallic haloid salts (platinum bichloride, iodide chloride), with mercury salts (see K. A. Hofmann and J. Sand, Ber., 1900, 33, p. 1340 et seq.), and those with a tertiary carbon atom yield double salts with zinc chloride.

In potassium permanganate oxidizes the olefines to glycols (C. Wagner, Ber., 1888, 21, p. 3359). With ozone they form oxonides (C. Harries, Ber., 1904, 37, p. 839). The higher members of the series readily polymerize in the presence of dilute sulphuric acid, zinc chloride, &c. For the first member of the series see ETHYLENE.

Propylene, CH₄H₆, may be obtained by passing the vapour of trimethylene through a heated tube (S. M. Tanatar, Ber., 1899, 32, p. 792, 1905). It is a colourless gas which may be liquefied by a pressure of 7 to 8 atm. of at least 3 atm. It is absorbed in water, and when the vapour is passed through a heated tube containing some "contact" substance, such as graphite, kieselguhr, &c. (see also J. B. Sendereis, Comptes rendus, 1907, 144, pp. 382, 1109).

They may also be prepared by eliminating the halogen hydrolyde from the alkyl halides by heating with alcoholic potash, or with litharge at 220° C. (A. Eltekov, Ber., 1878, 11, p. 414); by the action of metals on the halogen compounds C₆H₅Bu₂; by boiling the halogen compounds in the presence of anhydrous alkali, or by treating the halogen compounds with potassium hydride or with potassium hydroxide (Ber., 1876, 9, p. 543). C₆H₅H₂N = HNO₂ = N₂ + 2H₂O + CH₄; by the electrolysis of the alkali salts of saturated dicarboxylic acids; by the decomposition of β-halodial fatty acids with sodium carbonate, CH₂ = C(CH₃)COOH + Na₂CO₃ → CH₂ = C(CH₃)COONa + H₂O + CO₂ (Ber., 1885, 18, p. 2153); by the action of alkali on the barium salts of acids C₄H₈O₂ with sodium methyIate in vacuo (K. M. Ber., 1889, 22, p. 2135); from the higher alcohols by converting them into esters which are then distilled (F. Kraft, Ber., 1883, 16, p. 3018); CH₃CH₂CH₂COOH → C₆H₄CH₂CH₂CH₂CH₂OH + CO₂ + C₆H₄H₂CH₂CH₂COOH; from tertiary alcohols by the action of acetic anhydride in the presence of a small quantity of sulphuric acid (L. Henry, Comptes rendus, 1907, 144, p. 562); (CH₃)₂C(OH)CH₂ (CH₃)₂C(OH)CH₂ (CH₃)₂CH₂CH₂ (CH₃)₂CH₂CH₂ (CH₃)₂CH₂CH₂; from unsaturated alcohols by the action of metal-ammonium compounds (E. Chablay, Comptes rendus, 1906, 143, p. 123); 2C₆H₅CH₂CH₂OH + 2NH₂Na = C₆H₅CH₂CH₂CH₂OH + CH₄; and by the action of the zinc alkyls upon the halogen substituted compounds of the olefine.

A. Maithe (Chem. Zeits., 1906, 30, p. 37) has shown that on passing the monohalogen derivatives of the paraffins through a glass tube containing reduced nickel, copper or cobalt at 250° C., olefines are produced. It is believed that the halogen derivatives are first formed, and the reaction perhaps prevented by passing the gases through a solution of potash. The reaction probably proceeds thus: CH₂=CH₂ + C₁₀H₂₁Cl → CH₂Cl + C₁₀H₂₁Cl → CH₂=CH₂ + C₁₀H₂₁Cl, since the haloid derivatives of the monohalogen compounds are the same and show the same anhydroneous character, nickel, cobalt, cadmium, barium, iron and lead act in the same way as catalysts at about 300° C., and the bromides of lead, cadmium, nickel and barium at about 320° C.

In their physical properties, the olefines resemble the normal paraffins, the lower members of the series being inflammable gases, the members from C₄ to C₆ liquids insoluble in water, and from C₆ upwards of solids. The chief normal members of the series are shown in the table.

OLEG (7–912), prince of Kiev, succeeded Rurik, as being the eldest member of the ducal family, in the principality of Great Novgorod, the first Russian metropolis. Three years later he moved southwards and, after taking Smolensk and other places, fixed his residence at Kiev, which he made his capital. He then proceeded to build a fortress there and gradually compelled the surrounding tribes to pay him tribute, extending his conquests in all directions (883–903) at the expense of the Khazars, who hitherto had held all southern Russia to tribute.
OLEIC ACID—OLFACTORY SYSTEM

with a host made up of all the subject tribes, Slavonic and Finnic, he sailed against the Greeks in a fleet consisting, according to the lyceiopis, of 2,000 vessels, each of which held 40 men; but this estimate is plainly an exaggeration. On reaching Constantinople, Oleg disembarked his forces, mercilessly ravaged the suburbs of the imperial city, and compelled the emperor to pay tribute, provide the Russians with provisions for the return journey, and take fifty of them over the city. A formal treaty was then concluded, which the Slavonians swore to observe in the names of their gods Perun and Volos. Oleg returned to Kiev laden with golden ornaments, costly cloths, wines, and all manner of precious things. In 911 he sent an embassy of fourteen persons to Constantinople to get the former treaty confirmed and enlarged. The names of these ambassadors are preserved and they point to the Scandinavian origin of Oleg’s host; there is not a Slavonic name among them. A new and elaborate treaty, the terms of which have come down to us, was now concluded between the Russians and Greeks, a treaty which evidently sought to bind the two nations closely together and obviate all possible differences which might arise between them in the future. There was also to be free trade between the two nations, and the Russians might enter the service of the Greek emperor if they desired it. The envoy returned to Kiev in 912 after being shown the splendid of the Greek capital and being instructed in the rudiments of the Greek faith. In the autumn of the same year Oleg died and was buried at Kiev.

See S. M. Solovev, History of Russia (Russ.), vol. i. (St. Petersburg, 1885. &c.); M. F. Vladimirovitch-Budnov, Chronology of the History of Russian Law (Russ.), pt. i. (Kiev, 1886). (R. N. B.)

OLEIC ACID, C13H24O2 or C9H17·CH·CH2·[CH3]·CO2H, an organic acid occurring as a glyceride, triolein, in nearly all fats, and in many oils—olive, almond, cod-liver, &c. (see OILS). It appears as a by-product in the manufacture of candles. To prepare it olive oil is saponified with potash, and lead acetate added; the lead salts are separated, dried, and extracted with ether, which dissolves the lead oleate; the solution is then treated with hydrochloric acid, the lead chloride filtered off, the liquid concentrated, and finally distilled under diminished pressure. Oleic acid is a colourless, odourless solid, melting at 14° and boiling at 233° (10 mm.). On exposure it turns yellow, becoming rancid. Nitric acid oxidizes it to all the fatty acids from acetic to capric. Nitrous acid gives the isomeric eradic acid, C9H17·CH·[CH3]·CO2H, which is crystalline and melts at 51°. Hydriodic acid reduces both oleic and eradic acids to stearic acid.

Erucic acid, C17H35·CH·[CH3]·CO2H, and the isomeric brassid acid, belong to the oleic acid series. They occur as glycerides in rapeseed oil, in the fatty oil of mustard, and in the oil of grape-seed. Linoleic acid, C17H33·CH2·CO2H, found as glyceride in drying oils, and ricinoleic acid, C17H33·(OH)·CO2H, found as glyceride in castor oil, closely resemble oleic acid.

OLEN, a semi-legendary Greek bard and seer, and writer of hymns. He is said to have been the first priest of Apollo, his connexion with whom is indicated by his traditional birthplace—Lycia or the land of the Hyperboreans, favourite haunts of the god. The Delphian poetess Boco attributed to him the introduction of the cult of Apollo and the invention of the Apollo hymns. Many hymns, names (simple songs to accompany the circular dance of the chorus), and oracles, attributed to Olen, were preserved in Delos. In his hymns he celebrated Opis and Argé, two Hyperborean maidens who founded the cult of Apollo in Delos, and in the hymn to Eilithyia the birth of Apollo and Artemis and the foundation of the Delian sanctuary. His reputed Lycian origin corroborates the view that the cult of Apollo was an importation from Asia to Greece. His poetry generally was of the kind called hieratic.

See Callimachus, Hymn to Delos, 305; Pausanias i. 18; ii. 13; v. 7; ix. 27; x. 5; Herodotus iv. 35.

OLÉRON, an island lying off the west coast of France, opposite the mouths of the Charente and Seudre, and included in the department of Charente-Inférieure. In 1906 the population numbered 16,747. In area (66 sq. m.) it ranks next to Corsica among French islands. It is about 18 m. in length from N.W. to S.E., and 7 in extreme breadth; the width of the strait (Portus de Maumusson) separating it from the mainland is at one point less than a mile. The island is flat and low-lying and fringed by dunes on the coast. The greater part is very fertile, but there are also some extensive salt marshes, and oyster culture and fishing are carried on. The chief products are corn, wine, fruit and vegetables. The inhabitants are mostly Protestants and make excellent sailors. The chief places are St. Pierre (pop. 1532 in 1906), Le Château d’Oléron (1546), and the watering-place of St. Trojan-les-Bains.

Oléron, the Ólestr Insula of Pliny, formed part of the duky of Aquitaine, and finally came into the possession of the French crown in 1370. It gave its name to a medieval code of maritime laws promulgated by Eleanor of Guinevere.

OLFACTORY SYSTEM, in anatomy. The olfactory system consists of the outer nose, which projects from the face, and the nasal cavities, contained in the skull, which support the olfactory mucous membrane for the perception of smell in their upper parts, and act as respiratory passages below.

The bony framework of the nose is part of the skull (q.v.), but the outer nose is only supported by bone above; lower down its shape is kept by an "upper" and "lower lateral cartilage" and two or three smaller plates known as "cartilaginous minores."
bones (see fig. 2). Above the superior turbinate is a space between it and the roof known as the "recessus spheneno-ethmoidalis," into the back of which the "sphenoidal air sinus" opens. Between the superior and middle turbinate bones is the "superior meatus," containing the openings of the "posterior ethmoidal air cells," while between the middle and inferior turbinates is the "middle meatus," which is the largest of the three and contains a rounded elevation known as the "bulla ethmoidalis." Above and behind this is often an opening for the "middle ethmoidal cells," while below and in front a deep sickle-shaped gutter runs, the "hiatus semilunaris," which communicates above with the "frontal air sinus" and below with the opening into the "antrum of Highmore" or "maxillary antrum." So deep is this hiatus semilunaris that if, in the dead subject, water is poured into the frontal sinus it all passes into the

the sphenoidal turbinate bone separates the nasal cavity from the sphenoidal sinus above, and below there is an opening into the naso-phaeno-ethmoidalis known as the "posterior nasal aperture" or "choana." The mucous membrane of the outer wall is characteristic of the respiratory tract as high as the superior turbinate bone; it is ciliated all over and forms a large vessel where it covers the inferior turbinate; superficial to and above the superior turbinate the olfactory tract is reached and the specialized olfactory epithelium begins.

Embryology.

In the third week of intra-uterine life two pits make their appearance on the under side of the front of the head, and are known as the olfactory or nasal pits; they are the first structure of these olfactory region of the nose, and some of their epithelial lining cells send off axons (see Nervous System) which arborize with the dendrites of the cells of the olfactory lobe of the brain and are the olfactory nerves (see J. Disse, Anat. Hefte, 1897; also P. Anat. Soc., J. Anat. and Phys., 1897, p. 12). Between the olfactory pits the first media form a nasal process that grows down from the forehead region to form the dorsum of the nose (see fig. 3), and the anterior part of the nasal septum, while outside them the lateral nasal processes grow down, and later on meet the maxillary processes from the first visceral arch. In this way the nasal cavities are formed, but for some time they are separated from the mouth by a thin buccal membrane which eventually is broken through; after this the mouth and nose are one cavity until the formation of the palate in the third month (see Mouth and Salivary Glands). In the third month, Jacobson's organ may be seen as a well-marked tube lined with respiratory mucous membrane running upward and backward, close to the septum, from its orifice, which is just above the foramen of Stensen in the anterior palate canal. In man it never escapes any connexion with the olfactory membrane or olfactory nerves. Internally and below it is surrounded by a delicate sheet of cartilage, which is different from the bone of the nasal septum. No explanation of the function of Jacobson's organ in man is known, and it is probably entirely atavistic. At birth the nasal cavities are very shallow from above downward but they rapidly deepen till the age of puberty. The external nose at birth projects very little from the plane of the face except at the tip, which is very prominent in babies is well known. In the second and third year the bridge becomes more prominent, but after puberty the nose tends to the flatness of the newborn and ends to form the eminence which is seen at its best in the Roman nose. (For further details see Quain's Anatomy, vol. i., London, 1908.)

Comparative Anatomy.

In Amphioxus among the Acrania there is a ciliated pit above the anterior end of the central nervous system, which is probably a rudiment of an unpaired olfactory organ. In the Amblystoma (mudpuppies and hag) the pit is at first ventral, but later becomes dorsal and shares a common opening with the pituitary invagination. It furthermore becomes divided internally into two lateral halves. In fishes there are also two lateral pits, the nostril pits, which open sometimes, as in the elasmobranchs (sharks and rays), on to the ventral surface of the snout, and sometimes, as in the higher fishes, on to the dorsal surface. Up to this stage the olfactory organs are mere pits, but in the Dipnoi (mud-fish) an opening is established from them into the front of the roof of the mouth, and so they serve as respiratory passages as well as organs for the sense of smell. In the higher Amphibia the nasal organ becomes included in the skull and respiratory and olfactory parts are distinguished. In this class, too, turbinate ingrowths are formed, and the nasal septum appears. In the lizards, among the Reptilia, the olfactory and respiratory parts are very distinct, the latter being lined only by stratified epithelium connected with the olfactory nerves. There is no true turbinal bone growing from the septum wall, and close to this is a large nasal gland. In crocodiles the hard palate is formed, and there is henceforward a considerable distance between the openings of the external and internal nares. In this order, too (Crocodilia)

From R. Howden, in Cunningham's Text-Book of Anatomy.

Fig. 2.—View of the Outer Wall of the Nose—the Turbinated Bones having been removed.
1. Vestibule.
2. Opening of antrum of Highmore.
3. Hiatus semilunaris.
5. Agger nasi.
6. Opening of anterior ethmoidal cells.
7. Cut edge of superior turbinate bone.
8. Cut edge of middle turbinate bone.
Air sinuses are first found extending from the olfactory cavities into the skull-bones. The birds' arrangement is very like that of the reptiles; olfactory and respiratory chambers are present, and into the latter project the true turbinals, though there is a pseudo-turbinal in the upper or olfactory chamber. In mammals the olfactory chamber of the nose is variously developed; most of them are "macromastic," and have a large area of olfactory mucous membrane; some, like the seals, whalebone whales, monkeys and man are "micromastic," while the toothed whales have the olfactory region practically suppressed in the adult, and are said to be "anomastic.

There are generally five turbinal bones in macromastid mammals, so that man has a reduced number. The lowest of the series or "maxillo-turbinal" is the equivalent of the single true turbinal bone of birds and reptiles, and in most mammals is a double scroll, one

DISEASES OF OLFACTORY SYSTEM

External Affections and Injuries of the Nose.—Acute roacea is one of the most frequent nasal skin affections. In an early stage it consists of dilatation or congestion of the capillaries, and later of a hypertrophy of the sebaceous follicles. This may be accompanied by the formation of pus at the margin of the sebaceous glands, forming large protuberant nodular masses over which the dilated capillaries are plainly visible. This condition is termed "sebaceous nose." (rhinophyma or hammer nose), though there is no increase in fatty tissue. Nasal acute occurs mainly in those with acne, and may be accompanied, leading to much deformity if left untreated. The treatment is the immediate reposition of the bony fragments. The old-standing cases where there is considerable depression of the fragment, the treatment may cause subsequent nasal obstruction and require the straightening of the septum. In the Indian method of rhinoplasty a flap is cut from the forehead, to which it is left attached by a pedicle; the flap is then turned downwards to cover the missing portion of the bone. When the parts have united, the pedicle is cut through. In the Italian operation devised by Tagliacozzi, a flap was taken from the patient's scalp and turned backwards so that it can be grafted on the head until the flap has united.

Diseases of the Interior of the Nose.—Epistaxis or bleeding from the nose may arise from various causes, a particularly common in young girls at the time of puberty, being a form of vicarious menstruation. It also occurs in cerebral congestion, fits, rheumatic fever, scurvy, haemorrhagic fever, blood poisoning, and scrofula, typhus, and many other diseases; in some cases the disease is said to be due to various poisons or to the inhalation of fumes or smoke. In others the cause is not known. In any case the disease is said to be due to various poisons or to the inhalation of fumes or smoke. In cases when the patient has a history of smoking, the cause is usually a chronic inflammation of the nasal mucous membrane, and is called "chronic rhinitis.

Rhinitis, or inflammation of the mucous membrane of the nose, is one of the most common diseases, and is often due to the inhalation of cold air. The symptoms are aching, stuffiness, and a profuse nasal discharge, which is green in colour and thick in consistency. In some cases the discharge may be bloody, and the symptoms may be acute or chronic.

The treatment of rhinitis depends upon the cause. In cases with chronic rhinitis, various remedies may be used, such as saline or acid solutions, or even a caustic application to the nasal passage.
several distinct micro-organisms. Of these, the most important is the
Bacillus catarrhalis described by Martin Kichner in 1890, but
Friedlander’s pneuma-bacillus has also been found. In ordinary
cases of coryza, sneezing, congestion of the nasal mucous mem-
brane and a profuse watery discharge in the ear, and the inflam-
matory condition of the organs of the head, is directed towards
the middle turbinate bone, or an acute inflammation may
spread to the frontal sinuses giving rise to an erysipelas-like
locality. There is severe frontal pain, and in some cases a fulness
on the forehead over the affected side, the pus often pointing in this
site, or there may be a discharge of pus through the nose.
The treatment that condition and irritation depend upon the
scraping out of the sinus) and the re-establishment of
communication with the nose, with free drainage. The ethmoidal and sphenoidal
sinuses are also frequently the site of empyema, giving rise to
pain on the orbital and the bony parts of the nose, and a discharge into the
nasal pharynx. In the case of the ethmoidal sinus it may give rise to
exophtalmus and to strabismus (squint), with the formation of
a tumour at the inner wall of the orbit and fever and delirium at night.
In the case of the sphenoidal sinus may lead to blindness from
involvement of the sheath of the optic nerve, and dangerous complications
such as septic basal meningitis and thrombosis of the cavernous sinus may
occur. The treatment of this condition is desultory and severe operations
demanding immediate surgical intervention.

(H. L. H.)

OLGA, wife of Igor, prince of Kiev, and afterwards (from 945)
regent for Sviatoslav her son, was baptized at Constantinople
about 935 and died about 969. She was afterwards canonized
in the Russian church, and is now commemorated on the 11th
of July.

OLGIERD (d. 1377), grand-duke of Lithuania, was one of the
seven sons of Gedimins, grand-duke of Lithuania, among whom
he died in 1341 he divided his domains, leaving the
youngest, Yavvnutsy, in possession of the capital, Wilna, with a nominal
priority. With the aid of his brother Kiejest, Olgierd in 1345
drove out the incapable Yavnutsy and declared himself
grand-duke. The two and thirty years of his reign (1345-1377) were
dedicated to the development and extension of Lithuania, and he lived to make it one of the greatest states in Europe. Two
factors contributed to produce this result, the extraordinary
political sagacity of Olgierd and the life-long devotion of his
brother Kiejest. The Teutonic knights in the north and the
Tatar hordes in the south were equally bent on the subjection of
Lithuania, while Olgierd’s eastern and western neighbours,
Muscovy and Poland, were far more frequently hostile competitors
than serviceable allies. Nevertheless, Olgierd not only succeeded
in holding his own, but acquired influence and territory at the
expense of both Muscovy and the Tatars, and extended the
boundaries of Lithuania to the shores of the Black Sea. The principal
efforts of this eminent empire-maker were directed to securing
those of the Russian lands which had formed part of the ancient
grand-duchy of Kiev. He procured the election of his son
Andrew as prince of Polovts, and a powerful minority of the citizens
of the republic of Novgorod held the balance in his favour against
the Muscovite in the 1370s, and his ascendency in both these
commercial centres was at this period. On the other hand
he acquired permanently the important principalities of
Smolensk and Bryansk in central Russia. His relations with
the grand-dukes of Muscovy were friendly on the whole, and
twice he married orthodox Russian princesses; but this did not
prevent him from besieging Moscow in 1368 and again in 1372,
both times unsuccessfully. Olgierd’s most memorable feat was
his great victory over the Tatars at Siniya Vudii on the Bug in
1362, which practically broke up the great Kipchak horde and
compelled the khan to migrate still farther south and establish
his headquarters for the future in the Crimea. Indeed, but for the
unceasing simultaneous struggle with the Teutonic knights,
the burden of which was heroically borne by Kiejest, Russian
historians frankly admit that Lithuania, not Muscovy, must have
become the dominant power of eastern Europe. Olgierd died in
1377, accepting both Christianity and the tonsure shortly
before his death. His son Jagielo ultimately ascended the
Polish throne, and was the founder of the dynasty which ruled
Poland for nearly 200 years.

See Kazimierz Stadnitski, The Sons of Gedymins (Pol.) (Lemberg,
1849-1853); Vladimir Bonfatevich Antonovich, Monograph on
the History of Western Russia (Rus.), vol. i. (Kiev, 1885).

OLHÃO, a seaport of southern Portugal, in the district of
Faro; s. e. of Faro, on the Atlantic coast. Pop. (1900) 10,000.
Olhão has a good harbour at the head of the Barra Nova, a deep
channel among the sandy islands which fringe the coast. Wine,
fruit, cork, baskets and sumach are exported in small coating
vessels; there are important sardine and tunny fisheries; and
boats, sails, and cordage are manufactured.

**OLIGARCHY** (Gr. ὀλίγος, few, and ἀρχή, rule), in political
philosophy, the term applied to a government exercised by a relatively
small number of the members of a community. It is thus the
appropriate term for what is now generally known as "aristo-
cracy" (q.v.). The meaning of the terms has substantially altered
since Plato's day, for in the Republic "oligarchy" meant the rule of the wealthy, and "aristocracy" that of the really
best people.

**OLIGOCENE SYSTEM** (from the Gr. ὀλίγος, few, and καύς,
recent), in geology, the name given to the second division of the
older Tertiary rocks, viz. those which occur above the Eocene
and below the Miocene strata. These rocks were originally clas
ded by Sir C. Lyell as "older Miocene," the term Oligocene being
proposed by H. E. Beyrich in 1854 and again in 1858. Following
A. de Laparent, the Oligocene is here regarded as divided
into two stages, an upper one, the Etampien (from Étampes),
equivalent to the Rupelian of A. Dumont (1849), and a lower one,
the Samoilien (from Sanois near Paris), equivalent to the
Tongrian (from Tongris in Limburg) of Dumont (1859).

This lower division is the Ligurian of some authors, and corre-
sponds with the Lattorian (Lafot) of K. Mayer in north
Germany; it is in part the equivalent of the older term Ludian
of de Laparent. It should be pointed out that several authors
retain the Aquitanian stage (see Miocene) at the top of the
Oligocene, but there are sufficiently good reasons for removing
it to the younger system.

The Oligocene deposits are of fresh-water, brackish, marine
and terrestrial origin; they include soft sands, sandstones, grits,
shales, limestones, conglomerates and linites. The
geographical aspect of Europe during this period is indicated on
the accompanying map. Here and there, as in N. Germany,

In Britain Oligocene formations are found only in the Hampshire
Basin and the Isle of Wight; from the admixture of fresh-water,
marine and estuarine deposits, E. Forbes named these the "Fluvi-
marine series." The following are the more important subdivisions,
in the stratigraphic order: (1) the Upper, which is found at the top,
with Ostrea californica, Natica, &c., estuarine and fresh-
water below, with Unio, Viviparus and the remains of crocodiles,
turtles and mammals. The Benbridge marls, fresh-water, estuarine
and marine, are the remains of fresh-water fishes; they contain
many fresh-water fossils such as Limnaea, Planorbis, Chara, large land
snails, Amphidromus, Helix, Gastrina, and many insects and plant
leaves. The Osborne beds, marls, clays and limestones, with Unio, Littoralis,
and other freshwater molluscs, are followed by fresh-water, estuarine,
and marine, with the remains of Unio, Viviparus, and freshwater
fishes, such as, Silurus, Acipenser, Anguilla, and others.

In France the best-known tract of Oligocene rocks rests in the
Paris basin in close relationship with the underlying Eocene. These
beds are found at Lagny, in the environs of Paris; at Montmarte the
first or upper bed is 20 metres in thickness, and some of the beds contain siliceous nodules (fusils)
and numerous mammalian remains. Above the gypsum beds is the travertine of Chantilly, followed by fresh-water, estuarine,
and marine, with the remains of Unio, Viviparus, and freshwater
fishes, such as, Silurus, Anguilla, and others.

The sea gained ground that had been unoccupied by Eocene
waters, but important changes, associated with the continuation of
elevatory processes in the Pyrenees and Alps which had begun
in the preceding period, were in progress, and a general
relative uplifting took place which caused much of the Oligocene
sea floor to be occupied at this time by lake basins and lagoons.
The movements, however, were not all of a negative character
as regards the water areas, for oscillations were evidently
frequent, and subsidence must have been considerable in some
regions to admit of the accumulation of the great thickness
of material found deposited there. Perhaps the most striking
change from Eocene topography in Europe is to be seen in the
extension of the Oligocene sea over North Germany, whence
it extended eastward through Poland and Russia to the Aral-
Caspian region, communicating thence with Arctic waters by
way of a Ural depression. The Asian extension of the central
mediterranean sea appears to have begun to be limited. It was
later in the period when the wide-spread emersion set in.

In the Alpine region the Oligocene rocks assume the character
of the Flysch, a complex assemblage of marly and sandy shales and
soft sandstones with calcareous cement ("macigno"). The Flysch
series of deposition had begun before the closing period, but the bulk of it belongs to the Oligocene, and is especially
characteristic of the lower part. The Flysch may attain a very
great thickness; in Dauphiné it is said to be 2000 metres. Obscure plant-
skeletons and fossil groups are abundant in the Flysch of Italy,
with which certain beds in the Flysch of France are analogously
referred. In the flysch of Upper Italy, flysch, limestone, and sandstone
are seen, with nodules of marine algae, and with the remains of marine
fishes, such as, Silurus, Anguilla, and others.

OLIGOCLASE.—OLIPHANT, L.

In Belgium a sandy series (Wemmelian, Asschian, Heniian), mainly of brackish-water origin, is succeeded by the marine sands of Bergh (with the clay of Boom), which pass up through the inferior sands of Boulder clay into the Molasse. In Switzerland, beyond the limit of the Flysch, in the Alps, the Algat (alpine limestone) is a belt of grits, limestones and clays, an uncompactified condition, to which the name "molasse" is usually given; mixed with the molasse is an inconstant conglomeratic littoral formation, called Nagelfluh. The molasse occurs also in Bavaria, where it is several thousand feet thick and contains limestones. Oligocene deposits occur in the Carpathian region and Tirol; as Flysch and brackish and lacustrine beds with lignites in Klausenburg, lignites at Hărâng in Tirol. In the Spanish Pyrenees they are well developed; in the Apenines the scaly clays ("argille scaglioni") are of this age; while in Calabria they are represented by thick conglomerates and Flysch. Flysch appears also in Dalmatia and Istria (where it is called "tasselio") and in North Bosnia, where it contains marine limestones. Lignites are found at Sotzka and Krain in the Carpathian peninsula, glaucicritic sands prevail in South Russia, Flysch with sands and grits in the Carpathians, while marine deposits also occupy the Aral-Caspian region and Armenia, and are to be traced into Persia.

Oligocene rocks are known in North Africa, Algeria, Tunis and Egypt, with the silicified trees and leafy fossils which have been collected in the Sahara desert. In Florida, certain lacustrine clays in the Uinta basin, and by the riband shales with asphalt and petroleum in the coastal range of California. In South America and the Antilles upper Oligocene is found, in particular in the Carrao in Venezuela. In the Alps of Magellano may be of this age; in Patagonia are the lower Oligocene marine beds ("Patagonian") and beds with mammal remains. In New Zealand the Qamar series of J. Hutton is regarded as Oligocene; at its base are interstratified basic volcanic rocks.

A correlation of Oligocene strata is summarized in the following table:

The land flora of this period was a rich one consisting largely of evergreens with characters akin to those of tropical India and Australia and sub tropical America. Sequoas, sabaal palms, ferns, cinnamon-trees, gum-trees, oaks, figs, laurels and willows were common. Claro is a common fossil in the fresh-water beds. The most interesting feature of the land flora was the wonderful and astonishing variety of mammalians, especially the long series from the White river beds and others in the interior of North America. Pachyderms were very numerous. Many of the mammals were of mixed types, Hyaenodon (between mammals and placental Hyaena), Adapis (between pachyderms and lemurs), and many were clearly the forerunners of living genera. Rhinocerids were represented in the upper Oligocene by the hornless Aceratherium; Palaeomastodon and Priabona, from B. C., and Mesonyx, from Ohio, which may have lived in this period; Anchiatherium, Anchippus, &c., were forerunners of the horse. Palaeotherium, Anacoltherium, Palaeolophus, Steenbok, Cynodont, Dinita, Ictops, Palaeolagus, Sciurus, Colodon, Hypolimus, Orendo, Poebrotherium, Protoceras, Hydaspis, Ictops, Hyaenodon, and Protoceras, &c., are some of the important genera, representatives of most of the modern groups, including carniverous (Canidæ and Felidæ), insectivores, rodents, ruminants, camels. Tortoises were abundant, and the genus Rona made its appearance. Rays and dogfish were the dominant marine fish; logoonal brackish-water fish are represented by Proteobis, Smeris, &c. Insects abundantly and abandoned and arachnids were rapidly developing. Gasteropods were increasing in importance, most of the genera still existing (Cerithium, Potamidites, Melania, large Naticæ, Pterolampra, Volva, Turritella, Rostellaria, Pyrida), Cephalopods, on the other hand, such as the genus Cardia, Pachyconus, Laevia, Ostrea, Cornea, Cytherea, Bryozoa were extremely abundant (Membranipora, Leparia, Kerma, Témenus). Echinoids were less numerous than in the Eocene seas (Caelopleura, Echinolampadus, Clypeaster, Scutella). Corals were abundant, and nummulites still continued till near the close of the period, but they were diminished in size.

OLIGOCLASE, a rock-forming mineral belonging to the plagioclase (g.) division of the felspars. In chemical composition and in its crystallographic and physical characters it is intermediate between albite (NaAlSi₃O₈) and anorthite (Ca₂Al₂Si₂O₈), being an isomorphous mixture of three to six molecules of the former with one of the latter. It is thus a sodalime felspar crystallizing in the anorher system. Varieties intermediate between olikooclase and albite are known as oligoclase-albite. The name oligoclase was given by A. Breithaupt in 1826 from the Gr. os, little, and klas, to break, because the mineral was thought to have a less perfect cleavage than albite. It had previously been recognized as a distinct species by J. J. Berzelius in 1824, and was named by him soda-spodumene (Natron-spodumene), because of its resemblance in appearance to spodumene. The hardness is 6 and the sp. gr. 2.65-2.67. It colours usually white, with shades of grey, green or red. Perfectly colourless and transparent glassy material found at Bakersville in North Carolina has occasionally been faceted as a gem-stone. Another variety more frequently used as a gem-stone is the aventurine-felspar or "sun-stone" (g.) found as reddish cleavage masses in gneiss at Tvedestrand in southern Norway; this presents a brilliant red metallic glitter, due to the presence of numerous small scales of haematite or goethite enclosed in the felspar.

Oligoclases occur, often accompanying orthoclase, as a constituent of igneous rocks of various kinds; for instance, amongst plutonic rocks in granite, syenite, diorite; amongst dikes in porphyry and diabase; and amongst volcanic rocks in andesite and trachytes. It also occurs in gneisses. The best developed and largest crystals are those found with orthoclase, quartz, epidebe and calcite in veins in granite at Arendal in Norway. (L. J. S.)

OLIPHANT, LAURENCE (1829-1888), British author, son of Anthony Oliphant (1793-1859), was born at Cape Town.

1 The family to which Oliphant belonged is old and famous in Scottish history. Sir Laurence Oliphant of Aberdalgie, Perthsire, who was created Lord of the Scotts in 1456, was descended from Sir William Oliphant of Aberdalgie and the female side from King Robert the Bruce. Sir William (d. 1329) is renowned for his brave defence of Stirling castle against Edward I. in 1304. Sir Laurence was sent to conclude a treaty with England in 1484; he helped to establish the young king James IV. on his throne, and he died about 1500. His son John, the 2nd lord (d. 1516), having lost his son and heir, Colin, at Flodden, was succeeded by his grandson Laurence (d. 1566), who was taken prisoner by the English at the rout of Solway Moss in 1542. Laurence's son, Laurence the 4th lord (1529-1593), was a partisan of Mary queen of Scots, and was succeeded by his grandson Laurence (1583-1631), who left no sons when he died. The 6th lord was Patrick Oliphant, a descendant of the 4th lord, and the title was held by his descendants.
His father was then attorney-general in Cape Colony, but was soon transferred as chief justice to Ceylon. The boy's education was of the most desultory kind. Far the least useful portion of it belonged to the years 1838 and 1840, when he accompanied this parents on a tour on the continent of Europe. In 1843 he accompanied Jung Bahadur from Colombo to Nepal. He passed an agreeable time there, and saw enough that was new to enable him to write his first book, A Journey to Katmandu (1852).

From Nepal he returned to Ceylon and thence to England, dabbled a little with the English bar, so far at least as to eat dinners at Lincoln's Inn, and then with the Scottish bar, so far as to pass an examination in Roman law. He was more happily inspired when he threw over his legal studies and went to travel in Russia. The outcome of that tour was his book on The Russian Shores of the Black Sea (1853). Between 1853 and 1861 he was successively secretary to Lord Elgin during the negotiation of the Canada Reciprocity treaty at Washington, the companion of the duke of Newcastle on a visit to the Circassian coast during the Crimean War, and Lord Elgin's private secretary on his expedition to China. Each of these experiences produced a pleasant book of travel. In 1861 he was appointed first secretary in Japan, and might have made a successful diplomatic career if it had not been interrupted, almost at the outset, by a night attack on the legation, in which he nearly lost his life. It seems probable that he never properly recovered from this affair. He returned to England and resigned the service, and was elected to parliament in 1865 for the Stirling Burghs.

Oliphant did not show any conspicuous parliamentary ability, and made a great success by his vivacious and witty novel, Piccadilly (1870). He fell, however, under the influence of the spiritualist prophet Thomas Lake Harris (q.v.), who about 1861 had organized a small community, the Brotherhood of the New Life, which at this time was settled at Brocton on Lake Erie and subsequently moved to Santa rosa in California. Harris obtained so strange an ascendency over Oliphant that the latter left parliament in 1868, followed him to Brocton, and lived there the life of a farmer, in obedience to the imperious will of his spiritual guide. The cause of this painful and grotesque aberration has never been made quite clear. It was part of the Brocton régime that members of the community should be allowed to return to the world from time to time, to make money for its advantage. After three years this was permitted to Oliphant, who, when once more in Europe, acted as correspondent of The Times during the Franco-German War, and spent afterwards several years at Paris in the service of that journal. There he met Miss Alice le Strange, whom he married. In 1873 he went back to Brocton, taking with him his wife and mother. During his stay at Brocton Oliphant was very active in the service of the community and its head, but on work very different from that with which he had been occupied on his first sojourn. His new work was chiefly financial, and took him much to New York and a good deal to England. As late as December 1878 he continued to believe that Harris was an incarnation of the Deity. By that time, however, his mind was occupied with a large project of colonization in Palestine, and he made in 1879 an extensive journey in that country, going also to Constantinople, until the death of Francis, the 10th lord, in April 1878. It has since been claimed by several persons, but without success.

Another member of the family was Laurence Oliphant (1691-1767) the Jacobite, who belonged to a branch settled at Gask in Perthshire. He took part in the rising of 1715, and both he and his son (q.v.) were at one time confined in the Tower of London before being present at the battles of Falkirk and Culloden. After the ruin of the Stuart cause they escaped to France, but were afterwards allowed to return to Scotland. One of this Oliphant's descendants was the Rev. David Oliphant (1816-1904), editor of the Church of Scotland Official Gazette. (London, July 26, 1906) defends the purity of his character. It is difficult to arrive at the exact truth as to Oliphant's relations with him, or the financial scandal which ended them; and it must be admitted that Oliphant himself was at least decidedly cranky.

In the vain hope of obtaining a lease of the northern half of the Holy Land with a view to settling large numbers of Jews there. This he conceived would be an easy task from a financial point of view, as there were so many persons in England and America "anxious to fulfil the prophecies, and bring about the end of the world." He landed once more in England without having accomplished anything definite: but his wife, who had been banished from him for years and had been living in California, was allowed to rejoin him, and they went to Egypt together. In 1881 he crossed again to America. It was on this visit that he became utterly disgusted with Harris, and finally split from him. He was at first a little afraid that his wife would not follow him in his renunciation of "the prophet," but this was not the case, and they settled themselves very agreeably, with one house in the midst of the German community at Haifa, and another about twelve miles off at Dalieh on Mount Carmel.

It was at Haifa in 1884 that they wrote together the strange book called Sympontomata: Evolutionary Forces now active in Man, and in the next year Oliphant produced there his novel Masollam, which may be taken to contain its author's latest views with regard to the personage whom he long considered as "a new Avatar." One of his cleverest works, Alitira Peto, had been published in 1883. In 1886 an attack of fever, caught on the shores of the Lake of Tiberias, resulted in the death of his wife, whose constitution had been undermined by the hardships of her American life. He was persuaded that after death she was in much closer relation with her than she was still alive, and conceived that it was under her influence that he wrote the book to which he gave the name of Scientific Religion. In November 1887 he went to England to publish that book. By the Whit'suntide of 1888 he had completed it and started for America. There he determined to marry again, his second wife being a grand-daughter of Robert Owen the Socialist. They were married at Malvern, and meant to have gone to Haifa, but Oliphant was taken very ill at Twickenham, and died on the 23rd of December 1888. Although a very clever man and a delightful companion, full of high aspiration and noble feeling, Oliphant was only partially sane. In any case, his education was ludicrously inappropriate for a man who aspired to be an authority on religion and philosophy. He had gone through no philosophical discipline in his early life, and knew next to nothing of the subjects with regard to which he imagined it was in his power to pour a flood of new light upon the world. His shortcomings and eccentricities, however, did not prevent his being a brilliant writer and talker, and a notable figure in any society.

See Mrs (Margaret) Oliphant, Memoir of the Life of Laurence Oliphant and of Alice Oliphant his Wife (1862). (M. G. D.)

OLIPHANT, MARGARET OLIPHANT (1828-1897). British novelist and historical writer, daughter of Francis Wilson, was born at Wallyford, near Musselburgh, Midlothian, in 1828. Her childhood was spent at Lasswade (near Dalkeith), Glasgow and Liverpool. As a girl she constantly occupied herself with literary experiments, and in 1849 published her first novel, Passages in the Life of Mrs Margaret Maitland. It dealt with the Scottish Free Church movement, with which Mr and Mrs Wilson both sympathized, and had some success. This she followed up in 1851 with Caleb Field, and in the same year met Major Blackwood in Edinburgh, and was invited by him to contribute to the famous Blackwood's Magazine. The connexion thus early commenced lasted during her whole lifetime, and she contributed considerably more than 100 articles to its pages. In May 1852 she married her cousin, Frank Wilson Oliphant, at Birkenhead, and settled at Harrington Square, in London. Her husband was an artist, principally in stained glass. He had very delicate health, and two of their children died in infancy, while the father himself developed alarming symptoms of consumption. For the sake of his health they moved in January 1869 to Florence, and thence to Rome, where Frank Oliphant died. His wife, left almost entirely without resources, returned to England and took up the burden of supporting her three
children by her own literary activity. She had now become a popular writer, and worked with amazing industry to sustain her position. Unfortunately, her home life was full of sorrow and disappointment. In January 1864 her only daughter died in Rome, and was buried in her father's grave. Her brother, who had emigrated to Canada, was shortly afterwards involved in financial ruin, and Mrs Oliphant offered a home to him and his children, and added their support to her already heavy responsibilities. In 1866 she settled at Windsor to be near her sons who were being educated at Eton. This was her home for the rest of her life, and for more than thirty years she pursued a varied literary career with courage scarcely broken by a series of the gravest troubles. The ambitions she cherished for her sons were unfulfilled. Cyril Francis, the elder, died in 1890, leaving a Life of Alfred de Musset, incorporated in his mother's Foreif Classics for English Readers. The younger, Frank, collaborated with her in the Victorian Age of English Literature and won a position at the British Museum, but was rejected by the doctors. He died in 1894. With the last of her children lost to her, she had but little further interest in life. Her health steadily declined, and she died at Wimbledon, on the 25th of June 1897.

In the course of her long struggle with circumstances, Mrs Oliphant produced more than 120 separate works, including novels, books of travel and description, histories and volumes of literary criticism. Among the best known of her fiction are Adam Grome (1855), Magdalen Heburn (1854), Lilliedslof (1855), The Laird of Norlaw (1858) and a series of stories with the collective title of The Chronicles of Carlingford, which, originally appearing in Blackwood's Magazine (1862-1865), did much to widen her reputation. This series included Salem Chapel (1863), The Rector; and the Doctor's Family (1863), The Perpetual Curate (1864) and Miss Marjoribanks (1866). Other successful novels were Madonna Mary (1867), Squire Arden (1871), He that will not when he may (1880), Hester (1883), Kirsteen (1890), The Marriage of Elinor (1892) and The Ways of Life (1897). Her tendency to mysticism found expression in The Beleaguered City (1880) and A Little Pilgrim in the Unseen (1882). Her biographies of Edward Irving (1862) and Laurence Oliphant (1892), together with her life of Sheridan in the "English Men of Letters" (1833), have vivacity and a sympathetic touch. She also wrote historical and critical works of considerable variety, including Historical Sketches of the Reign of George II. (1869), The Makers of Florence (1876), A Literary History of England from 1790 to 1825 (1882), The Makers of Venice (1887), Royal Edinburgh (1890), Jerusalem (1891) and The Makers of Modern Rome (1895). While at the time of her death she was still occupied upon Annals of Journalism, a Publishing House, a record of the progress and achievement of the firm of Blackwood, with which she had been so long and honourably connected.

Her Autobiography and Letters, which present a touching picture of her domestic anxieties, appeared in 1890.

OLIPHANT, OLIFANT (Ger. Halfont), the large-signal horn of the middle ages, made, as its name indicates, from the tusk of an elephant. The oliphant was the instrument of knights and men of high degree, and was usually ornamented with scenes of hunting or war carved either lengthways or round the horn in sections divided by bands of gold and studded with gems. The knights used their olipphants in the hunting field and in battle, and the loss of this precious horn was considered as shameful as the loss of sword or banner.

OLIVA, FERNAN PEREZ DE (1492-1530), Spanish man of letters, was born at Cordova about 1492. After studying at Salamanca, Alcalá, Paris and Rome, he was appointed rector at Salamanca, where he died in 1530. His Dicdlogo de la dignidad del hombre (1543), an unfinished work completed by Francisco Cervantes de Salazar, was written chiefly to prove the suitability of Spanish as a vehicle for philosophic discussion. He also published translations of the Amphitrite (1523), the Electra (1528) and the Helen (1528).

OLIVARES, GASPAR DE GUZMAN, count of Olivares and duke of San Lucar (1587-1645), Spanish royal favourite and minister, was born in Rome, where his father was Spanish ambassador, on the 6th of January 1587. His compound title is explained by the fact that he inherited the title of count of Olivares from his mother, and of San Lucar de Barrameda from his father, Philip IV. He begged the king to allow him to preserve his inherited title in combination with the new honour—according to a practice of which there are a few other examples in Spanish history. Therefore he was commonly spoken of as el condeduque. During the life of Philip III he was appointed to a post in the household of the heir apparent, Philip, by the interest of his maternal uncle Don Baltasar de Zuñiga, who was the head of the prince's establishment. Olivas made it his business to acquire the most complete influence over the young prince. When Philip IV. ascended the throne in 1621, at the age of sixteen, he showed his confidence in Olivas by ordering that all papers requiring the royal signature should first be sent to the count-duke. Olivas could now boast to his uncle Don Baltasar de Zuñiga that he was "all." He became what is known in Spain as a valido—something more than a prime minister, the favourite and alter ego of the king. For twenty-two years he directed the policy of Spain. It was a period of constant war, and finally of disaster abroad and of rebellion at home. The Spaniards, who were too thoroughly monarchical to blame the king, held his favourite responsible for the misfortunes of the country. The count-duke became, and for long remained, in the phrase of his countrymen, the accepted model of a grasping and incapable favourite. Of late, largely under the inspiration of Don Antonio Canovas, there has been a certain reaction in his favour. It would certainly be most unjust to blame Olivas alone for the decadence of Spain, which was due to internal causes of long standing. The gross errors of his policy—the renewal of the war with Holland in 1621, the persistence of Spain in taking part in the Thirty Years' War, the lesser wars undertaken in northern Italy, and the entire neglect of all effort to promote the unification of the different states forming the peninsula—were shared by him with the king, the Church and the commercial classes. When he had fallen from power he wrote an apology, in which he maintained that he had always wished to see more attention paid to internal government, and above all to the complete unification of Portugal with Spain. But if this was not an afterthought, he must, on his own showing, stand accused of having carried out during long years a policy which he knew to be disastrous to his country, rather than risk the loss of the king's favour and of his place. Olivas did not share the king's taste for art and literature, but he formed a vast collection of state papers, ancient and contemporary, which he endeavoured to protect from destruction by entailing them as an heirloom. He also formed a splendid aviary which, under the name of the "hencoop," was a favourite subject of ridicule with his enemies. Towards the end of his period of favour he caused great offence by legitimizing a supposed bastard son of very doubtful paternity and worthless personal character, and by arranging a rich marriage for him. The fall of Olivas was immediately due to the revolts of Portugal and Catalonia in 1640. The king parted with him reluctantly, and only under the pressure of a strong court intrigue headed by Queen Isabella. It was noted with anxiety by his enemies that he was succeeded in the king's confidence by his nephew the count of Haro. There remains, however, a letter from the king, in which Philip tells his old favourite, with frivolous ferocity, that it might be necessary to sacrifice his life in order to avert unpopularity from the royal house. Olivas was driven from office in 1643. He retired by the king's order to Toro. Here he endeavoured to satisfy his passion for activity, partly by sharing in the municipal government of the town and the regulation of its commons, woods and pastures, and partly by the composition of the apology he published under the title of El Nicandro, which was perhaps written by an agent, but was undeniably inspired by the fallen minister. The Nicandro was denounced to the Inquisition, and it is not impossible that Olivas might have ended in the prisons of the Holy Office, or on the scaffold, if he had not died on the 22nd of July 1645.
See the Estudios del reinado de Felipe IV, of Don Antonio Canovas (Madrid, 1889); and Don F. Silveira's introduction, much less favourable to Olivares, to his edition of the Cartas de Sor Maria de Agreda y del rey Felipe IV. (Madrid, 1885-1886).

**OLIVE** (*Olea europaea*), the plant that yields the olive oil of commerce, belonging to a section of the natural order Oleaceae, of which it has been taken as the type. The genus *Olea* includes about thirty species, very widely scattered, chiefly over the Old World, from the basin of the Mediterranean to South Africa and New Zealand. The wild olive is a small tree or bush of rather straggling growth, with thorny branches and opposite oblong pointed leaves, dark greyish-green above and, in the young state, hoary beneath with whitish scales; the small white flowers, with four-clifted calyx and corolla, two stamens and bifid stigma, are borne on the last year's wood, in racemes springing from the axils of the leaves; the drupaceous fruit is small in the wild plant, and the fleshy pericarp, which gives the cultivated olive its economic value, is hard and comparatively thin. In the cultivated forms the tree acquires a more compact habit, the branches lose their spiny character, while the young shoots become more or less angular; the leaves are always hoary on the under-side, and are generally lanceo- late in shape, though varying much in breadth and size in the different kinds. The fruit is subject to still greater changes of form and colour; usually oval or nearly globular, in some sorts it is egg-shaped, in others much elongated; while the dark hue that it commonly assumes when ripe is exchanged in many varieties for violet, green or almost white. At present the wild olive is found in most of the countries around the Mediter- ranean, grown in the wild state and cultivated, to a certain extent, in Portugal, and eastward to the vicinity of the Caspian, while, locally, it occurs even in Afghanistan. An undoubted native of Syria and the maritime parts of Asia Minor, its abundance in Greece and the islands of the Archipelago, and the frequent allusions to it by the earliest poets, seem to indicate that it was there also indigenous; but in localities remote from the Levant it may have escaped from cultivation, reverting more or less to its primitive type. It shows a marked preference for calcareous soils and a partiality for the sea-breeze, flourishing with especial luxuriance on the limestone slopes and crags that often form the shores of the Greek peninsula and adjacent islands.

The varieties of olive known to the modern cultivator are extremely numerous—according to some authorities equalling or exceeding in number those of the vine. In France and Italy at least thirty kinds have been enumerated, but comparatively few are grown to any large extent. None of these can be safely identified with ancient descriptions, though it is not unlikely that some of the narrow-leaved sorts that are most esteemed may be descendants of the famed "Licinian" (see below). Greece retains its old pre-eminence in olive cultivation; and, though its ancient Gallic province now excels it in the production of the finer oils, its fast-improving culture may restore the old prestige. The broad-leaved olive trees of Spain bear a larger fruit, but the pericarp is of more bitter flavour and the oil of ranker quality. The olive tree, even when free increase is unchecked by pruning, is of very slow growth; but, where allowed for ages its natural development, the trunk sometimes attains a considerable diameter. De Candolle records one in Spain 22 ft. in diameter, being supposed to amount to seven centuries. Some old Italian olive trees are credited with an antiquity reaching back to the first years of the empire, or even to the days of republican Rome; but the age of such ancient trees is always doubtful during growth, and their identity with old descriptions still more difficult to establish. The tree in cultivation rarely exceeds 30 ft. in height, and in France and Italy is generally confined to much more limited dimensions by frequent pruning. The wood, of a yellow or light greenish-brown hue, is often finely veined with a darker tint, and, being very hard and close-grained, is valued by the cabinetmaker and ornamental turner.

The olive is propagated in various ways, but cuttings or layers are generally preferred; the tree roots in favourable soil almost as easily as the willow, and throws up suckers from the stump when cut down. Branches of various thickness are cut into lengths of several feet each, and planted rather deeply in manured ground, soon vegetate; shorter pieces are sometimes laid horizontally in shallow trenches, when covered with a few inches of soil, they rapidly throw up sucker-like shoots. In Greece and the islands grafting the cultivated tree on the wild olive is a common practice. Studied buds, which form small swellings on the stems, are carefully excised and planted beneath the surface, where they grow readily, these "ovoili" soon forming a vigorous shoot. Occasionally the larger boughs are incised, and young trees thus obtained. The olive is also sometimes raised from seed, the oily pericarp being first softened by slight rotting, or soaking in hot water or in an alkaline solution, to facilitate germination. The olives in the East often receive little attention from the husbandman, the branches being allowed to grow freely, but curtailment by the pruning-knife, however, must be supplied in long droughts to ensure a crop; with this neglectful culture the trees bear abundantly only at intervals of three or four years; thus, although wild growth is favourable to the picturesque, it is not to be recommended for economic grounds. Where the olive is carefully cultivated, as in Languedoc and Provence, it is planted in rows at regular intervals, the distance between the trees varying in different "olivettes," according to the variety grown. Careful pruning is practised, the object being to preserve the flower-bearing shoots of the preceding year, while keeping the head of the tree low, so as to allow the easy gathering of the fruit; a dome or rounded form is generally the aim of the grower. The spaces between the trees are occasionally manured with rotten dung or other nitrogenous matter, and France woolen rags are in high esteem for this purpose. Various annual crops are sometimes raised between the rows, and in Calabria wheat is grown in the winter, but the trees are better without any intermediate cropping. Later the olive is dressed with green fruit, has come into favour in certain localities, especially in America, where it is said to have produced a crop two or three seasons after planting. The ordinary kinds do not become profitable to grow, however, until from five to seven years after the young shoots are placed in the olive-ground. Apart from occasional damage by weather or organic foes, the olive crop is somewhat precarious even with the most careful cultivation, and the large undertened trees so often seen in Spain and Italy do not yield that certain income to the peasant proprietor that some authors have attributed to them; the crop from these old trees is often enormous, but they seldom bear well two years in succession, and in many instances a luxuriant harvest can only be reaped upon every second or even fourth season. The fruit when ripe is, by the careful grower, picked by hand and deposited in cloth baskets or conveyance to the mill; but in many parts of Spain and Greece, and generally in Asia, the olives are sometimes taken down by shaking the boughs, or even allowed to drop naturally, often lying on the ground until the convenience of the owner admits their removal; much of the inferior oil owes its bad quality to the carelessness of the proprietor of the trees.

In southern Europe the olive harvest is in the winter months, commenced by the lowly grower until from five to seven years after the young shoots are placed in the olive-ground. The amount of oil contained in the fruit differs much in the various sorts; the pericarp usually yields from 60 to 70%. The ancient agriculturists believed that the olive oil could be made from the leaves of Pinus pinea, the ancient resin of Italy (see below). The ancient olive oil was obtained from the sea (Theophrastus gives 900 stadia as the limit), but modern experience does not confirm the idea, and, though showing a preference for the coast, it has long been grown far inland. A calcareous soil or one of low clay seems best adapted to its healthy development, though the tree will grow in any light soil, and even on clay if well drained; but, as remarked by Pliny, the plant is more liable to disease on rich soils, and the oil is inferior to the produce of the poorer and more rocky ground the species naturally affects. The olive suffers greatly in some years from the attacks of various fungi. A fungoid growth has at times infested the trees for several
successive seasons, to the great damage of the plantations. A species of coccus, C. oleae, attaches itself to the shoots, and certain lepidopterous caterpillars feed on the leaves, while the "olive-fly" attacks the fruit. In France the olives suffer occasionally from frost; in the early part of the 15th century many trees were cut to the ground by a winter of exceptional Gales and long-continued rains during the gathering season also cause mischief.

The unripe fruit of the olive is largely used in modern as in ancient times—an article of dessert, to enhance the flavour of wine, and to renew the sensitiveness of the palate for other viands. For this purpose the fruit is picked while green, soaked for a few hours in an alkaline ley, washed well in clean water and then placed in bottles or jars in the same ley; the Romans added amures to the salt to increase the bitter flavour of the olives, and at the present day spices are sometimes used.

The leaves and bark of the tree are employed in the south, as a tonic medicine, in intermittent fevers. A resumes the "olive-juice" or Lucca gum, formed by the exuding juice in hot seasons, was anciently in medical esteem, and in modern Italy is used as a perfume.

In England the olive is not hardy, though in the southern counties it will stand wintry winters with only the protection of a wall, and will bear fruit in such situations; but the leaves are generally shed in the autumn, and the olives rarely ripen.

The genus Olea includes several other species of some economic importance. O. punctata is a larger tree, attaining a height of 50 or 60 ft. in the forests of Queensland, and yielding a hard and tough timber. The yet harder wood of O. laurofolia, an inhabitant of Natal, is the black ironwood of the South African colonist.

At what remote period of human progress the wild olive passed under the care of the husbandman and became the fruitful garden olive is impossible to conjecture. The frequent reference in the Bible to the plant and its produce, its implied abundance in the land of Canaan, the important place it has always held in the economy of the inhabitants of Syria, lead us to consider that country the birthplace of the cultivated olive. An improved variety, possessed at first by some small Semitic sepi, it was probably slowly distributed to adjacent tribes; and, yielding profusely, with little labour, that oily matter so essential to healthy life in the dry hot climates of the East, the gift of the fruitful tree became in that primitive age a symbol of peace and goodwill among the warlike barbarians. At a later period, with the development of maritime enterprise, the oil was conveyed, as an article of trade, to the neighbouring Pelasgic and Ionian nations, and the plant, doubtless, soon followed.

In the Homeric world, as depicted in the Iliad, olive oil is known only as a luxury of the wealthy—an exotic product, prized chiefly for its value in the heroic toilet; the warriors anointed themselves with it after the bath, and the body of Patroclus is similarly sprinkled; but no mention of the culture of the plant is made, nor does it find any place on the Achillian shield, on which a vineyard is represented. But, although no reference to the cultivation of the olive occurs in the Iliad, the presence of the tree in the garden of Alcinous and other familiar allusions show it to have been known when the Odyssey was written. Whenever the introduction may have taken place, all tradition points to the limestone hills of Attica as the seat of its first cultivation on the Hellenic peninsula. When Poseidon and Athena contended for the future city, an olive sprang from the barren rock at the bidding of the goddess, the patron of those arts that were to bring undying influence to the rising state. That this myth has some relation to the first planting of the olive in Greece seems certain from the remarkable story told by Herodotus of the Epidaurians, who, on their crops failing, applied for counsel to the Delphic oracle, and were enjoined to erect statues to Damia and Auxesia (symbols of fertility) carved from the wood of the true olive, then possessed only by the Athenians, who granted their request for a tree on condition of making an annual sacrifice to Athena, its patron; they thus obeyed the command of the Pythian, and their lands became again fertile. The sacred tree of the goddess long stood on the Acropolis, and, though destroyed in the Persian invasion, sprouted again from the root—some suckers of which were said to have produced those olive trees of the Academy in an after age no less revered. By the time of Solon the olive had so spread that he found it necessary to enact laws to regulate the cultivation of the tree in Attica, from which country it was probably distributed gradually to all the Athenian allies and tributary states. To the Ionian coast, where it abounded in the time of Thales, it may have been in an earlier age brought by Phoenician vessels; some of the Sporades may have received it from the same source; the olives of Rhodes and Crete had perhaps a similar origin. Samos, if we may judge from the epitaph of Aeschylus (Δαράβορος), must have had the fruitful plant long before the Persian wars.

It is not unlikely that the valued tree was taken to Magna Graecia by the first Achaean colonists, and the assertion of Pliney (quoted from Fenestella), that no olives existed in Italy in the reign of Tarquiniius Priscus, must be received with the caution due to many statements of that industrious compiler. In Latin Italy the cultivation seems to have spread slowly, for it was not until the consulship of Pompey that the production of oil became sufficient to permit of its exportation. In Pliny's time it was already grown abundantly in the two Gallic provinces and in Spain; indeed, in the earlier days of Strabo the Ligurians supplied the Alpine barbarians with oil, in exchange for the wild produce of their mountains; the plant may have been introduced into those districts by Greek settlers in a previous age. Africa was indebted for the olive mainly to Semitic agencies. In Egypt the culture never seems to have made much progress; the oil found in Theban tombs was probably imported from Syria. Along the southern shore of the great inland sea the tree was carried by the Phoenicians, at a remote period, to their numerous colonies in Africa—though the abundant olives of Cyrena, to which allusion is made by Theophrastus, and the glaucous foliage of whose descendants still clothes the rocks of the deserted Cyrenaica, may have been the offspring of Greek plants brought by the first settlers. The tree was most likely introduced into southern Spain, and perhaps into Sardinia and the Balearic Islands, by Phoenician merchants; and, if it be true that old olive trees were found in the Canaries on their rediscovery by medieval navigators, the venerable trees probably owed their origin to the same enterprising pioneers of the ancient world. De Candolle says that the means by which the olive was distributed to the two opposite shores of the Mediterranean are indicated by the names given to the plant by their respective inhabitants—the Greek έλαιον passing into the Latin olea and olivo, that in its turn becoming the ulivo of the modern Italian, the olivo of the Spaniard, and the olive, olivier, of the French, while in Africa and southern Spain the olive retains appellatives derived from the Semitic sisi or seti; but the complete subjugation of Barbary by the Saracens sufficiently accounts for the prevalence of Semitic forms in that region; and aceytuna (Arab. zeytun), the Andalusian name of the fruit, locally given to the tree itself, is but a vestige of the Moorish conquest.

Yielding a grateful substitute for the butter and animal fats consumed by the races of the north, the olive, among the southern nations of antiquity, became an emblem not only of peace but of national wealth and domestic plenty; the branches borne in the Panathenaea, the wild olive spray of the Olympic victor, the olive crown of the Roman conqueror at ovation, and those of the equites at their imperial review alike typified gifts of peace that, in a barbarous age, could be secured by victory alone. Among the Greeks the oil was valued as an important article of diet, as well as for its external use. The Roman people employed it largely in food and cookery—the wealthy as an indispensable adjunct to the toilet; and in the luxurious days of the later empire it became a favourite axiom that long and pleasant life depended on two fluids, "wine within and oil without." Pliny vaguely describes fifteen varieties of olivé cultivated in his day, that called the "Licianian" being held in most esteem, and the oil obtained from it at Venafrum in Campania the finest known to Roman connoisseurs; the produce of Istria and Baetica was regarded as second only to that of the Italian peninsula. The gour- met of the empire valued the unripe fruit, steeped in brine, as a provocative to the palate, no less than his modern representative;
and pickled olives, retaining their characteristic flavour, have been found among the buried stores of Pompeii. The bitter juice or refuse deposited during expression of the oil (called amouroa), and the astringent leaves of the tree have many virtues attributed to them by ancient authors. The oil of the bitter wild olive was employed by the Roman physicians in medicine, but does not appear ever to have been used as food in the culinary art.

In modern times the olive has been spread widely over the world; and, though the Mediterranean lands that were its ancient home still yield the chief supply of the oil, the tree is now cultivated successfully in many regions unknown to its early distributors. Soon after the discovery of the American continent it was conveyed thither by the Spanish settlers. In Chile it flourishes as luxuriantly as in its native land, the trunk sometimes becoming of large girth, while oil of fair quality is yielded by the fruit. To Peru it was carried at a later date, but has not there been equally successful. Introduced into Mexico by the Jesuit missionaries of the 17th century, it was planted by similar agency in Upper California, where it has prospered latterly under the more careful management of the Anglo-Saxon conqueror. Its cultivation has also been attempted in the south-eastern states, especially in S. Carolina, Florida and Mississippi. In the eastern hemisphere the olive has been established in many inland districts which would have been anciently considered ill-adapted for its culture. To Armenia and Persia it was known at a comparatively early period of history, and many olive-yards now exist in Upper Egypt. The tree has been introduced into Chinese agriculture, and has become an important addition to the resources of the Australian planter. In Queensland the olive has found a climate especially suited to its wants; in South Australia, near Adelaide, it also grows vigorously; and there are probably few coast districts of the vast island-continent where the tree would not flourish. It has likewise been successfully introduced into some parts of Cape Colony.

OLIVEIRA MARTINS, JOAQUIM PEDRO DE (1845-1894), Portuguese writer, was born in Lisbon and received his early education at the Liceo Nacional and the Academia das Bellas Artes. At the age of fourteen his father’s death compelled him to seek a living as clerk in a commercial house, but he gradually improved his position until in 1870 he was appointed manager of the mine of St Eufemia near Cordova. In Spain he wrote O. Socialismo, and developed that sympathy for the industrial classes of which he gave proof throughout his life. Returning to Portugal in 1874, he became administrator of the railway from Oporto to Povoa, residing in Oporto. He had married when only nineteen, and for many years devoted his leisure hours to the study of economics, geography and history. In 1878 his memoir A Circulação fiduciaria brought him the gold medal and membership of the Royal Academy of Sciences of Lisbon. Two years later he was elected president of the Society of Commercial Geography of Oporto, and in 1884 he became director of the Industrial and Commercial Museum in that city. In 1885 he entered public life, and in the following year represented Vianna do Castello in parliament, and in 1887 Oporto. Removing to Lisbon in 1888, he continued the journalistic work which he had commenced when living in the north, by editing the Regator, and in 1889 he was named a delegate to the International Exhibition. He represented Portugal at international conferences in Berlin and Madrid in 1890, and was chosen to speak at the celebration of the fourth centenary of Columbus held in Madrid in 1891, which gained him membership of the Spanish Royal Academy of History. He became minister of finance on the 15th of January 1892, and later vice-president of the Junta do Crédito Publico. His health, however, began to break down as a result of a life spent in unremitting toil, and he died on the 24th of August 1894.

His youthful struggles and privations had taught him a serious view of life, which, with his acute sensibility, gave him a reserved manner, but Oliveira Martins was one of the most generous and noble of men. Like Anheiro de Quental, he was impregnated with modern German philosophy, and his perception of the low moral standard prevailing in public life made him a pessimist who despairs of his country’s future, but his sense of proportion, and the necessity which impelled him to work, saved him from the fate which beset his friend, and he died a believing Catholic. At once a gifted psychologist, a profound sociologist, a moralist, and an ardent patriot, Oliveira Martins deserved his European reputation. His Biblioteca das ciencias sociais, a veritable encyclopaedia, comprises literary criticism, socialism, economics, anthropology, histories of Iberian civilization, of the Roman Republic, Portugal and Brazil. Towards the end of his life he specialized in the 15th century and produced two notable volumes, Os filhos de D. João I. and A vida de Num’Alvares, leaving unfinished O príncipe perfeito, a study on King John II., which was edited by his friend Henrique de Barros Gomes.

As the literary leader of a national revival, Oliveira Martins occupied an almost unique position in Portugal during the last third of the 19th century. If he judged and condemned the parliamentary régime and destroyed many illusions in his sensational Contemporaneo Portugues, and in his philosophic History of Portugal he showed, in a series of impressionist pictures, the slow decline of his country commencing in the golden age of the discoveries and conquests, he at the same time directed the gaze of his countrymen to the days of their real greatness under the House of Aviz, and incited them to work for a better future by describing the faith and patriotism which had animated the foremost men of the race in the middle ages. He had neither time nor opportunity for original research, but his powerful imagination and picturesque style enabled him to evoke the past and make it present to his readers.

The chief characteristics of the man—psychological imagination combined with realism and a gentle irony—make his strength as a historian and his charm as a writer. When some critics objected that his Historia de Portugal ought rather to be named ‘Ideas on Portuguese History,’ he replied that a synthetic and dramatic picture of one of those collective beings called nations gives the mind a clearer, truer and more lasting impression than a summary narrative of successive events. But just because he possessed the talents and temperament of a poet, Oliveira Martins was fated to make frequent mistakes as well as to discover important truths. He must be read with care because he is emotional, and cannot let facts speak for themselves, but interrupts the narrative with expressions of praise or blame. Some of his books resemble a series of visions, while, despite his immense erudition, he does not always supply notes or refer to authorities. He can draw admirable portraits, rich with colour and life; in his Historia de Portugal and Contemporaneo de Portugal those of King Pedro I. and Herculano are among the best known. He describes to perfection such striking events as the Lisbon earthquake, and excels in the appreciation of an epoch. In these respects Castelar considered him superior to Macauly, and declared that few men in Europe possessed the universal amplitude and the fullness of knowledge displayed by Oliveira Martins.

The works of Oliveira Martins include Elementos de antropologia, As Raças humanas e a civilização primitiva, Systema dos mybios unidos, O quadro das instituições primitivas, O Regento das riquezas, Política e economia nacional, Taboas de cronologia e geographia historica, O Helenismo e a civilização cristã, Historia da República Romana, Historia da civilização ibérica, Historia de Portugal, Amazónia e Brasil, Portugal nas Américas, Portugal em África, Portugal contemporaneo, Camões os Astúridos e a renascença em Portugal—a brilliant commentary on the physiognomy of the poet and his poem, Os Filhos de D. João I., the preface to which gives his views on the writing of history;—A Vida de Num’Alvares; and A Inglaterra de hoje—the result of a visit to England.

See Menis Barreto, Oliveira Martins, estudo de psicologia (Paris, 1887), a remarkable study; F. Díaz D’Aylla, Os Ideais de Oliveira Martins (Lisbon, 1897), which contains an admirable statement of his ideas, philosophical and otherwise; Anheiro de Quental, Oliveira Martins (Lisbon, 1894) and Dicionario bibliográfico português, xii. 125. (E. Pr.)

OLIVENITE, a mineral consisting of basic copper arsenate with the formula Cu₃(OH)AsO₄. It crystallizes in the ortho-
rhombic system, and is sometimes found in small brilliant crystals of simple prismatic habit terminated by domal faces. More usually, however, it occurs as globular aggregates of acicular crystals, these fibrous forms often having a velvety lustre: sometimes it is lamellar in structure, or soft and earthy. A characteristic feature, and one to which the name alludes (German, 
Olivenet, of A. G. Werner, 1789), is the olive-green colour, which varies in shade from blackish-green in the crystals to almost white in the finely fibrous variety known as "wood-
copper." The hardness is 3, and the sp. gr. 4-3. The mineral was formerly found in some abundance, associated with 
iminite and quartz, in the upper workings in the copper mines of 
the St Day district in Cornwall; also near Redruth, and in 
the Tintic district in Utah. It is a mineral of secondary origin, 
having been formed by the alteration of copper ores and 

dispickel.
The arsenic of olivenite is sometimes partly replaced by a small amount of phosphorus, and in the species libethene we have 
the corresponding basic copper phosphate CuOHPO₄. This 
is found as small dark green crystals resembling olivenite at 
Libethen in Hungary, and in small amount also in Cornwall. 
Other members of this isomorphous group of minerals are adamite, 
ZnNa₂CO₃·4H₂O (Knowles, L. J. S.)

OLIVER, ISAAC (c. 1566–1617), English miniature painter, was 
probably born in London, as in 1571 a certain Peter Oliver of 
Rouen was residing in London with his wife and had been there 
for three years with one "chylde" named "Isake." It would 
seem likely, therefore, that he was not at that time more than six 
years old. It has been suggested by Mr Lionel Cust, from the 
Huguenot records, that he is identical with one Isaac Oliver of 
Rouen, married at the Dutch church in Austin Friars in 1602. 
He was probably a pupil of Nicholas Hilliard, and connected through his wife, whose name is 
unknown, with the artists Gheeraerts and De Critz. He was an 
exceedingly expert miniature painter, and splendid examples of 
his work can be seen at Montagu House, Windsor Castle, Sher-
borne Castle and in the collections of Mr J. Pierpont Morgan 
and the late Baronsess Burdett-Coutts. Some of his pen draw-

ings are in the British Museum.

OLIVER, PETER (1594–1648), English miniature painter, was 
the eldest son of Isaac Oliver, probably by his first wife; 
and to this Isaac Oliver left behind unfinished and unfinished 
drawings, with the hope that he would live long enough to 
carry on the art of his father. The younger sons of the artist appear to 
have been under age at the time of his death, and were probably 
therefore sons by a later wife than the mother of Peter Oliver. 
He resided at Isleworth, and was buried beside his father at 
St Anne's, Blackfriars. He was even more eminent in mini-
ature painting than his father, and is specially remarkable for a 
series of copies in water-colour he made after celebrated pictures by old masters. Most of these were done by the desire of 
the king, and seven of them still remain at Windsor Castle. A great 
many of Oliver's works were purchased by Charles II. from 
his widow; several of his drawings are in existence, and a leaf from 
his pocket-book in the collection of the earl of Derby. His most 
important work is the group of the three grandsons of the 1st 
Viscount Montacute with their servant, now belonging to the 
marquess of Exeter; and there are fine miniatures by him at 
Welebeck Abbey, Montagu House, Sherborne Castle, Minley 
Manor, Belvoir Castle and in the private collection of the queen 
of Holland.

OLIVES, MOUNT OF, or MOUNT OLIVET ("Oros Elymous or 
Oros Elymous, mod. Jebel-el-Tur"), the ridge facing the Temple 
Mount at Jerusalem on the east, and separated from it by the 
Kidron. A basis of hard cretaceous limestone is topped with 
sloper deposits of the same, quaternary deposits forming the 
summit. There are four distinct elevations in the ridge: tradi-
tionally the southernmost, which is separated by a cleft from the 
others, is called the "Hill of Offence," and said to be the scene of 
Solomon's idolatry. The summit to the north of this is often 
(wrongly) spoken of as Olivet proper. Still worse is the error of 
calling the next hill but one to the north "Scopus." The top of 
the ridge affords a comprehensive view. There are four Old 
Testament references: 2 Sam. xv. 30 sqq., Neh. viii. 15, Ezek. xix. 
13, Zech. xiv. 4. In the New Testament the place is mentioned 
in connexion with the last days of the life of Jesus. He crossed 
it on his kingly entry into Jerusalem, and upon it he delivered 
his great eschatological address (Mark xiii. 3). That the Ascension 
took place from the summit of the Mount of Olives is not necessarily 
implicated in Acts i. 12; the words "over against Bethany" 
(Luke xxiv. 50) perhaps mean one of the secluded ravines on 
the eastern slope, beside one of which that village stands. But 
since Constantine erected the "Basilica of the Ascension" on the 
spot marked by a certain sacred cave (Euseb. Vila Const. iii. 41), 
the site of this event has been placed here and marked by a 
succession of churches. The present building is quite modern, 
and is in the hands of the Moslems. Close to the Chapel of 
The Ascension is the vault of St Helene, and a little way down the 
hill is the labyrinth of early Christian rock-hewn sepulchral 
chambers now called the "Tombs of the Prophets." During 
the middle ages Olivet was also shown as the mount of the 
Transfiguration. A chapel, bearing the name of the Caliph Omar, 
and said to occupy the place where he encamped when Jerusalem 
surrendered to the Moslems, formerly stood beside the Church 
of St. Helena. There is a considerable number of monasteries 
and churches of various religious orders on the slopes of the hill, 
from whose beauty their uniform and unremarked ugliness 
merits. On Easter day 1907 was laid the foundation of a hospice for pilgrims, under the patronage of the German 
empress.

OLIVETANS, one of the lesser monastic orders following the 
Benedictine Rule, founded by St Bernard Tolomei, a Siene 
ese nobleman. At the age of forty, when the leading man in Siena, 
he retired along with two companions to live a hermit's life at 
Accona, a desert place fifteen miles to the south of Siena, 1313. 
Soon others joined him, and in 1324 John XXII. approved of 
the formation of an order. The Benedictine Rule was taken as 
the basis of the life; but austerities were introduced beyond 
what St Benedict prescribed, and the government was framed 
on the mendicant, not the monastic, model, the superiors being 
appointed only for a short term of years. The habit is white. 
Partly from the olive trees that abound there, and partly out of 
devotion to the Passion, Accona was christened Monte Oliveto, 
whence the order received its name. By the end of the 14th 
century there were about 100 monasteries, chiefly in Italy; and in the 18th there were still another eight, one of the most 
considerable being San Miniato at Florence. The monastery of 
Monte Oliveto Maggiore is an extensive building of considerable 
artistic interest, enhanced by frescoes of Signorelli and Sodoma; 
it is now a national monument occupied by two or three monks 
as custodians, though it could accommodate three hundred. The 
Olivetans have a house in Rome and a few others, including one 
founded in Austria in 1890. There are about 125 monks in all, 
54 being priests. In America there are some convents of Olivetan 

nuns.

See Helyot, Hist. des ordres religieux (1718), vi. c. 24; Max 
Heimbucher, Orden u. Kongregationen (1907), i. § 50; Weitzen 
U. Welte, Kirchenlexicon (ed. 2); J. A. Symonds, Sketches and 
Studies in Italy (1898), "Monte Oliveto." B. M. Maréchaux, Vie du bien-
heureux Bernard Tolomei (1888).

OLIVIER, JUSTE DANIEL (1807–1879), Swiss poet, was born 
near Nyon in the canton of Vaud; he was brought up as a 
peasant, but studied at the college of Nyon, and later at 
the academy of Lausanne. Though originally intended for the 
military, his poetic genius (forshadowed by the prizes 
he obtained in 1825 and 1828 for poems on Marcus Bourdet 
and Julia Alpina respectively) inclined him towards literary 
studies. He was named professor of literature at Neuchâtel 
(1830), but before taking up the duties of his post made a literary 
visit to Paris, where he completed his education and became associated 
with Ste Beuve, especially from 1837 onwards. He professed 
history at Lausanne from 1833 to 1846, when he lost his chair 
in consequence of the religious troubles. He then went to Paris,
where he remained till 1870, earning his bread by various means, but being nearly forgotten in his native land, to which he remained tenderly attached. From 1845 till 1860 (when the magazine was merged in the Bibliothèque universelle) Ollivier and his wife wrote in the Revue suisse the Paris letter, which had been started by Ste Beuve in 1843, when Ollivier became the owner of the periodical. After the war of 1870 he settled down in Switzerland, spending his summers at his beloved Gryon, and died at Geneva on the 7th of January 1876. Besides some novels, a semi-poetical work on the Canton of Vaud (2 vols., 1837-1841), and a volume of historical essays entitled Études d'histoire nationale (1842), he published several volumes of poems, Deux Voix (1835), Chansons lointaines (1847) and its continuation Chansons du soir (1867), and Sentiers de montagne (Gryon, 1875). His younger brother, Urbain (1810-1888), was well known from 1856 onwards as the author of numerous popular tales of rural life in the Canton of Vaud, especially of the region near Nyon.

Life by Rambert (1875), re-published in his Écrits de la Suisse romande (1889), and also prefixed to his edition of Ollivier's Œuvres choisies (Lausanne, 1879).

OLIVINE, a rock-forming mineral composed of magnesium and ferrous orthosilicate, the formula being (Mg, Fe)SiO₄. The name olivine, proposed by A. G. Werner in 1790, alludes to the olivine-green colour commonly shown by the mineral. The transparent varieties, or “precious olivine” used in jewelry, are known as chrysolite (q.v.) and peridot (q.v.). The term olivine is often applied incorrectly by jewelers to various green stones.

Olivine crystallizes in the orthorhombic system, but distinctly developed crystals are comparatively rare, the mineral more often occurring as compact or granular masses or as grains and blebs embedded in the igneous rocks of which it forms a constituent part. There are distinct cleavages parallel to the macropinacoid (M in the fig.) and the brachypinacoid. The hardness is 6½; and the sp. gr. 3.27-3.37, but reaching 3.57 in the highly ferruginous variety known as hylasoliderite. The amount of ferrous oxide varies from 5 (about 9% in the gem variety) to 30% in hylasoliderite. The depth of the green, or yellowish-brown colour, also varies with the amount of iron. The lustre is vitreous. The indices of refraction (1.66 and 1.70) and the double refraction are higher than in many other rock-forming minerals; and these characters, together with the distinct cleavage, enable the mineral to be readily distinguished in thin rock-sections under the microscope. The mineral is decomposed by hot hydrochloric acid with separation of gelatinous silica. Olivine often contains small amounts of nickel and titanium dioxide; the latter replaces silica, and in the variety known as titan-olivine reaches 5%.

Olivine is a common constituent of many basic and ultrabasic rocks, such as basalt, diabase, gabbro and peridotite; the dunite, of Dun Mountain near Nelson in New Zealand, is an almost pure olivine-rock. In basalts it is often present as small poikilitic crystals or as large granular aggregates. It also occurs as an accessory constituent of some granular dolomitic limestones and crystalline schists. With enstatite it forms the bulk of the material of meteoric stones; and in another type of meteorites large blebs of glassy olivine fill spaces in a cellular mass of metallic iron.

Olivine is especially liable to alteration into bornite (hydrated magnesium silicate); the alteration proceeds from the outside of the crystals and grains or along irregular cracks in their interior, and gives rise to the separation of iron oxides and an irregular net-work of fibrous serpentine, which in rock-sections presents a very characteristic appearance. Large greenish-yellow crystals from Snarum in Buskerud, Norway, at one time thought to be crystals of serpentine, really consist of serpentine pseudo-morphous after olivine. Many of the large rock-masses of serpentine have been derived by the serpentinization of olivine-rocks. Olivine also sometimes alters, especially in crystalline schists, to a fibrous, colourless amphibole, to which the name lineite has been given. By ordinary weathering processes it alters to limonite and silica.

Closely related to olivine are several other species, which are included together in the olivine group: they have the orthosilicate formula R₂SiO₄ where R² represents calcium, magnesium, iron, manganese and rarely zinc; they all crystallize in the orthorhombic system, and are isomorphous with olivine. The following may be mentioned—

Monticellite, CaMgSiO₄, a rare mineral occurring as yellowish-green blebs and grains in granular limestone at Monte Somma, Vesuvius.

Forsterite, Mg₂SiO₄, as colourless or yellowish grains embedded in many crystalline limestones.

Fayalite, Fe₂SiO₄, or iron olivine is dark brown or black in colour. It occurs as nodules in a volcanic rock at Fayal in the Azores, and in granite at the Mountains in Ireland; and as small crystals in cavities in rhyolite at the Yellowstone Park, U.S.A. It is a common constituent of crystalline iron slags.

Tephroite, Mn₂SiO₄, a grey (tephrite, ash-coloured), cleavable mineral occurring with other manganeseiferous minerals in Sweden and New Jersey.

OLIVIER, OLIVIER ÉMILE (1825- ), French statesman, was born at Marseilles on the 2nd of July 1825. His father, Léon Maximilien Ollivier (1790-1884), was a vehement opponent of the July monarchy, and was returned by Marseilles to the Constituent Assembly in 1848. His opposition to Louis Napoleon led to his banishment after the coup d'état of December 1851, and he only returned to France in 1859. On the establishment of the short-lived Second Republic his father's influence with Ledru-Rollin secured for Émile Ollivier the position of commissary-general of the department of Bouches-du-Rhône. Ollivier was then twenty-three and had just been called to the bar. Less radical in his political opinions than his father, he repudiated with a socialist outbreak at Marseilles commended him to General Cavaignac, who continued him in his functions by making him prefect of the department. He was shortly afterwards removed to the comparatively unimportant prefecture of Chaumont (Haute-Marne), a semi-disgrace which he ascribed to his father's enemies. He therefore resigned from the civil service to take up practice at the bar, where his brilliant abilities assured his success.

He re-entered political life in 1857 as deputy for the 3rd circumscription of the Seine. His candidature had been supported by the Sûtele, and he joined the constitutional opposition. With Alfred Darimon, Jules Favre, J. L. Hénin and Ernest Picard he formed the group known as Les Cing, which wrung from Napoleon III. some concessions in the direction of constitutional government. The imperial decree of the 24th of November, permitting the insertion of parliamentary reports in the Moniteur, and an address from the Corps Législatif in reply to the speech from the throne, were welcomed by him as a first instalment of reform. This acquiescence marked a considerable change of attitude, for only a year previously a violent attack on the imperial government, in the course of a defence of Étienne Vacherot, brought to trial for the publication of La Démocratie, had resulted in his suspension from the bar for three months. He gradually separated from his old associates, who grouped themselves around Jules Favre, and during the session of 1866–1867 Ollivier formed a third party, which definitely supported the principle of a Liberal Empire. On the last day of December 1866, Count A. F. J. Walewski, acting in continuance of negotiations already begun by the duc de Morny, offered Ollivier the ministry of education with the function of representing the general policy of the government in the Chamber. The imperial decree of the 10th of January 1867, together with the promise inserted in the Moniteur of a relaxation of the stringency of the press laws and of concessions in respect of the right of public meeting, failed to satisfy Ollivier's demands, and he refused office. On the eve of the general election of 1869 he published a manifesto, Le 19 janvier, in justification of his policy. The sénatus-consulte of the 8th of September 1869 gave the two chambers the ordinary
OLMSTED, D.—OLMSTED, F. L.

Ollivier's own view of his political life is given in his L'Empire liberal, which must always be an important "document" for the history of his time; but the book must be treated with no less caution than respect.

OLMSTED, DENISON (1791-1859), American man of science, was born at East Hartford, Connecticut, U.S.A., on the 18th of June 1791, and in 1813 graduated at Yale, where he acted as college tutor from 1815 to 1817. In the latter year he was appointed to the chair of chemistry, mineralogy and geology in the university of North Carolina. This chair he exchanged for that of mathematics and physics at Yale in 1825; in 1836, when this professorship was divided, he retained that of astronomy and natural philosophy. He died at New Haven, Connecticut, on the 13th of May 1859.

His first publication (1824-1825) was the Report of his geological survey of the state of North Carolina. It was followed by various text-books on natural philosophy and astronomy, but he is chiefly known to the scientific world for his observations on hail (1830), on meteors and on the aurora borealis (see Smithsonian Contributions, vol. viii.).

OLMSTED, FREDERICK LAW (1822-1903), American landscape architect, was born in Hartford, Connecticut, on the 27th of April 1822. From his earliest years he was a wanderer. When still a lad he shipped before the mast as a sailor; then he took a course at Yale. Soon his sales of several hundred acres of land to farmers; and, finally, began farming for himself on Staten Island, where he met Calvert Vaux, with whom later he formed a business partnership. All this time he wrote for the agricultural papers. In 1850 he made a walking tour through England, his observations being published in Walks and Talks of an American Farmer in England (1852). A horseback trip through the Southern States was recorded in A Journey in the Seacoast Slaves State (1856), A Journey through Texas (1857) and A Journey in the Back Country (1860). These three volumes, reprinted in England in two as Journeys and Explorations in the Cotton Kingdom (1861), gave a picture of the conditions surrounding American slavery that had great influence on British opinion, and they were much quoted in the controversies at the time of the Civil War. During the war he was the untrusting secretary of the U.S. Sanitary Commission. He happened to be in New York City when Central Park was projected, and, in conjunction with Vaux, proposed the plan which, in competition with more than thirty others, won first prize. Olmsted was made superintendent to carry out the plan. This was practically the first attempt in the United States of a systematic scheme of the improvement of public parks; it attracted great attention, and the work was so satisfactorily done that he was engaged thereafter in most of the important works of a similar nature in America—Prospect Park, Brooklyn; Fairmount Park, Philadelphia; South Park, Chicago; Riverside and Morningside Parks, New York; Mount Royal Park, Montreal; the grounds surrounding the Capitol at Washington, and at Leland Stanford University at Palo Alto (California); and many others. He took the bare stretch of lake front at Chicago and developed it into the beautiful World's Fair grounds, placing all the buildings and contributing much to the architectural beauty and the success of the exposition. He was greatly interested in the Niagara reservation, made the plans for the park there, and also did much to influence the state of New York to provide the Niagara Park. He was the first commissioner of the National Park of the Yosemite and the Mariposa Grove, directing the survey and taking charge of the property for the state of California. He had also held directing appointments under the cities of New York, Boston, Philadelphia, Baltimore, Wilmington and San Francisco. As a joint committee of the Senate and House of Congress, the Niagara Falls Reservation Commission, the trustees of Harvard, Yale, Amherst and other colleges and public institutions. Subsequently to 1856 he was largely occupied in laying out an extensive system of parks and parkways for the city of Boston and the town of Brookline, and on a scheme of landscape improvement of Boston harbour. Olmsted received honorary degrees from Harvard, Amherst and Yale in 1864, 1867 and 1893. He died on the 28th of August 1903.
OLMÜTZ (Czech, Olomouc or Holoumouc), a town of Austria, in Moravia, 67 m. N.E. of Brünn by rail. Pop. (1900) 21,933, of which two-thirds are Germans. It is situated on the March, and is the ecclesiastical metropolis of Moravia. Until 1866 Olmütz was one of the strongest fortresses of Austria, but the fortifications have been removed, and their place is occupied by a town-park, gardens and promenades. Like most Slavonic towns, it contains several large squares, the chief of which is adorned with a trinity column, 115 ft. high, erected in 1740. The most prominent church is the cathedral, a Gothic building of the 14th century, restored in 1833-1856, with a tower 328 ft. high and the biggest church-bell in Moravia. It contains the tomb of King Wenceslaus III., who was murdered here in 1306. The Mauritius church, a fine Gothic building of the 15th century, and the St Michael church are also worth mentioning. The principal secular building is the town-hall, completed in the 15th century, flanked on one side by a Gothic chapel, transformed now into a museum. It possesses a tower 250 ft. high, adorned with an astronomical clock, an artistic and famous work, executed by Anton Polll in 1422. The old university, founded in 1570 and suppressed in 1780, is a three-storied building which contains a valuable library and an important collection of manuscripts and early prints. Olmütz is an important railway junction, and is the emporium of a busy mining and industrial district. Its industries include brewing and distilling and the manufacture of malt, sugar and starch.

Olmütz is said to occupy the site of a Roman fort founded in the imperial period, the original name of which, Mons Julii, has been gradually corrupted to the present form. At a later period Olmütz was long the capital of the Slavonic kingdom of Moravia, but it ceded that position to Brünn in 1630. The Mongols were defeated here in 1241 by Yaroslav von Sternberg. During the Thirty Years' War it was occupied by the Swedes for eight years. The town was originally fortified by Maria Theresa during the wars with Frederick the Great, who besieged the town unsuccessfully for seven weeks in 1758. In 1848 Olmütz was the scene of the emperor Ferdinand's abdication, and in 1859 an important conference took place here between Austrian and German statesmen. The bishopric of Olmütz was founded in 973, and raised to the rank of an archbishopric in 1777. The bishops were created princes of the empire in 1588. The archbishop is the only one in the Austrian empire who is elected by the cathedral chapter.

OLNEY, RICHARD (1835- ), American statesman, was born at Oxford, Massachusetts, on the 13th of September 1835. He graduated from Brown University in 1856, and from the Law School of Harvard University in 1858. In 1859 he began the practice of law at Boston, Massachusetts, and attained a high position at the bar. He served in the state house of representatives in 1874, and in March 1893 became attorney-general of the United States in the cabinet of President Cleveland. In this position, during the strike of the railway employees in Chicago in 1894, he instructed the district attorneys to secure from the Federal Courts writs of injunction restraining the strikers from acts of violence, and thus set a precedent for "government by injunction." He also advised the use of Federal troops to quell the disturbances in the city, on the ground that the government must prevent interference with its mails and with the general railway transportation between the states. Upon the death of Secretary W. Q. Gresham (1832-1895), Olney succeeded him as secretary of state on the 10th of June 1895. He became specially prominent in the controversy with Great Britain concerning the boundary dispute between the British and Venezuelan governments (see VENEZUELA), and in his correspondence with Lord Salisbury gave an extended interpretation to the Monroe Doctrine which went considerably beyond previous statements on the subject. In 1897, at the expiration of President Cleveland's term, he returned to the practice of the law.

OLNEY, a market town in the Buckingham parliamentary division of Buckinghamshire, England, 59 m. N.W. by N. of London, on a branch of the Midland railway. Pop. of urban district (1901) 2634. It lies in the Fen valley of the Ouse on the left bank of the river. The church of St Peter and St Paul is Decorated. It has a fine tower and spire; and the chancel has a northerly inclination from the alignment of the nave. The town is chiefly noted for its connexion with William Cowper, who came to live here in 1767 and remained until 1786, when he removed to the neighbouring village of Weston Underwood. His house and garden at Olney retain relics of the poet, and the house at Weston also remains. In the garden at Olney are his favourite seat and the house in which he kept his tame hares. John Newton, curate of Olney, had the assistance of Cowper in the production of the collection of Olney Hymns. The trade of Olney is principally agricultural; the town also shares in the manufacture of boots and shoes common to many places in the neighbouring county of Northampton.

OLNEY, a city and the county-seat of Richland county, Illinois, U.S.A., about 30 m. W. of Vincennes, Indiana. Pop. (1900) 4012. The site of Olney was acquired by the Baltimore & Ohio South-western, the Illinois Central, and the Cincinnati, Hamilton & Dayton railways, and is a terminus of the Ohio River Division of the last. It has a Carnegie library and a city park of 55 acres. Olney is an important shipping point for the agricultural products of this district; oil is found in the vicinity; and the city has various manufactures. The municipality owns its water-works. Olney was settled about 1842 and was first chartered as a city in 1867.

OLONETS, a government of north-western Russia, extending from Lake Ladoga almost to the White Sea, bounded W. by Finnland, N. and E. by Archangel and Vologda, and S. by Novgorod and St Petersburg. The area is 27,422 sq. m., of which 6794 sq. m. are lakes. Its north-western portion belongs geographically and geologically to the Finland region; it is thickly dotted with hills reaching 1000 ft. in altitude, and diversified by numberless smaller ridges and hollows running from north-west to south-east. The rest of the government is a flat plateau sloping towards the marshy lowlands of the south. The geological structure is very varied. Granites, syenites and diorites, covered with Laurentian metamorphic slates, occur extensively in the north-west. Near Lake Onega they are overlain with Devonian sandstones and limestones, yielding marble and sandstone for building; to the south of this lake Carboniferous limestones and clays make their appearance. The whole is sheeted with boulder-clay, the bottom moraine of the great ice-sheet of the Glacial period. The entire region bears traces of glaciation, either in the shape of scratchings and elongated grooves on the rocks, or of eskers (ässar, selgos) running parallel to the glacial striations. Numberless lakes occupy the depressions, while a great many have left evidences of their existence in the extensive marshes. Lake Onega covers 3764 sq. m., and reaches a depth of 400 ft. Lakes Zeg, Vyg, Lacha, Loksha, Tulos and Vodl cover from 140 to 480 sq. m. each, and their crustaceous fauna indicates a former connexion with the Arctic Ocean. The south-eastern part of Lake Ladoga falls also within the government of Onolents. The rivers drain to the Baltic and White Sea basins. To the former system belong Laked Ladoga and Onega, which are connected by the Svir and receive numerous streams; of these the Vytega, which communicates with the Mariinsk canal-system, and the Oyat, an affluent of Lake Ladoga, are important for navigation. Large quantities of timber, fire-wood, stone, metal and flour are annually shipped on waters belonging to this government. The Onega river, which has its source in the south-east of the government and flows into the White Sea, is of minor importance. Thirty-three per cent of the area of Onolents is occupied by forests; those of the crown, maintained for shipbuilding purposes, extend to a known area of 500,000 acres. The climate is harsh and moist, the average yearly temperature at Petrozavodsk (61° 8' N.) being 33°6 F. (12°6 in January, 57°4 in July); but the thermometer rarely falls below -35° F.
The population, which numbered 321,250 in 1881, reached 367,902 in 1897, and 401,100 (estimate) in 1906. They are principally Great Russians and Finns. The two parishes belong mostly to the Orthodox Greek Church, or are nonconformists. Rye and oats are the principal crops, and some flax, barley, and turnips are grown, but the total cultivated area does not exceed 25% of the whole government. The chief source of wealth is timber, next to which come fishing and hunting. Mushrooms and berries are exported to St Petersburg.

There are quarries, iron-mills, saw-mills, tanneries, iron-works, distilleries and flour-mills. More than one-fifth of the entire male population leave their homes every year in search of temporary employment. Olonets is divided into seven districts, of which the chief towns are Petrozavodsk, Kargopol, Lodeinoe Pole, Olonets, Poyvenets, Pudozh and Vytna. It includes the Olonets mining district, a territory belonging to the crown, which covers 432 sq. m. and extends into the Sredobol district of Finland; the ironworks were begun by Peter the Great in 1701-1714. Olonets was colonized by Novgorod in the 13th century, and though it suffered much from Swedish invasion its towns soon became wealthy trading centres. Ivan III. annexed it to the principality of Moscow in the second half of the 16th century.

OLOPAN, OLOPUEN or OLOPEN (probably a Chinese form of the Syriac Rabban, i.e. monk; fl. A.D. 635), the first Christian missionary in China (setting aside vague stories of St Thomas, St Bartholomew, &c.), and founder of the Nestorian Church in the Far East. According to the Si-ning-fu inscription, our sole authority, Olopan came to China from Ta T’sin (the Roman empire) in the ninth year of the emperor T’ai-Tsung (A.D. 635), bringing sacred books and images. He was received with favour; his teaching was examined and approved; his Scriptures were translated for the imperial library; and in 638 an imperial edict declared Christianity a tolerated religion. T’ai-Tsung’s successor, Kao-Tsung (650-683), was still more friendly, and Olop now became a “guardian of the empire” and “lord of the great law.” After this followed (c. 683-744) a time of disfavour and oppression for Chinese Christians, followed by a revival dating from the arrival of a fresh missionary, Kiho, from the Roman empire.

The Si-ning-fu inscription, which alone records these facts, was erected in 781, and rediscovered in 1625 by workmen digging in the Chang-ning suburb of Si-ning-fu city. It consists of 1789 Chinese characters, giving a history of the Christian mission down to 781, together with a sketch of Nestorian doctrine, the decree of T’ai-Tsung in favour of Christianity, the date of erection, and names of various persons connected with the church in China when the monument was put up. Additional notes in Syriac (Estrangelo characters) repeat the date and record the names of the reigning Nestorian patriarch, the Nestorian bishop in China, and a number of the Nestorian clergy.

Fauthier, De l’authenticité de l’inscription nesterienne de Si-ning-fou (Paris, 1857); L’inscription syro-chinoise de Si-ning-fou (Paris, 1858); Henry Yule, Cathay, Preliminary Essay, xii.-xiv. clxxi.-clxxxiii. (London, Hakluyt Soc., 1866); F. Hirth, China and the Roman Orient, 323 &c.; Father Hirth’s translation of the T’ai-Tsung edict (issued Nov. 8th, 638 anon., and history) published out of three (Shanghai, 1865 and 1897); Dr James Legge’s edition and translation of the text, The Nestorian Monument of Hsii-an-Fu (London, 1888); Yule and Cordier, Marco Polo’s Travels (translated, with introduction and notes, London, 1903); C. R. Beazley, Dawn of Modern Geography, i. 215-218.

OLORON-SAINTE-MARIE, a town of south-western France, capital of an arrondissement in the department of Basses-Pyrénées, 21 m. S.W. of Pau on a branch of the Southern railway. It lies at the confluence of the mountain torrents (locally known as gaves) Aspe and Ossau, which, after dividing into three parts, unite to form the Oloron, a tributary of the Pau. The united population of the old feudal town of Sainte-Croix or Oloron proper, which is situated on an eminence between the two rivers, of Sainte-Marie on the left bank of the Aspe, and of the new quarters on the right bank of the Ossau, is 7271. Oloron has remains of old ramparts and pleasant promenades with beautiful views, and there are several old houses of the 13th, 16th and 17th centuries, one of which is occupied by the hôtel de ville. The church of Sainte-Croix, the building of most interest, belongs mainly to the 14th century; the chief feature of the exterior is the central Byzantine cupola; in the interior there is a large altar of gilded wood, constructed in the Spanish style of the 17th century. The church of Sainte-Marie, which formerly served as the cathedral of Oloron, is in the old ecclesiastical quarter of Sainte-Marie. It is a medley of various styles from the 11th to the 14th century. A square tower at the west end shelters a fine Romanesque portal. In the new quarter there is the modern church of Notre-Dame. Remains of a castle of the 14th century are also still to be seen. Oloron is the seat of a sub-prefect, and its public institutions include tribunals of first instance and of commerce, and a chamber of arts and manufactures. It is the most important commercial centre of its department after Bayonne, and carries on a thriving trade with Spain by way of the passes of Somport and Anso.

A Celtiberian and then a Gallo-Roman town, known as Iuro, occupied the hill on which Sainte-Croix now stands. Devastated by the Vascons in the 6th and by the Saracens in the 8th century, it was abandoned, and it was not until 1839 that the quarter of Sainte-Marie was re-established by the bishops.

In 1860 the viscount of Béarn took possession of the old town. The two quarters remained distinct till the union of Béarn with the crown at the accession of Henry IV. At the Reformation the place became a centre of Catholic reaction. In the 17th century it carried on a considerable trade with Aragon, until the Spaniards, jealous of its prosperity, pillaged the establishments of the Oloron merchants at Saragossa in 1694—a disaster from which it only slowly recovered. The bishopric was suppressed in 1790.

OLSHAUSEN, HERMANN (1796-1839), German theologian, was born at Oldeslohe in Holstein on the 21st of August 1796, and was educated at the universities of Kiel (1814) and Berlin (1816), where he was influenced by Schleiermacher and Neander. In 1820 he became Privatdozent and in 1821 professor extraordinarius at Berlin; in 1827 professor at Königsberg, in 1834 at Erlangen. He died on the 4th of September 1839. Olshausen’s department was a New Testament exegesis; his Commentary (completed and revised by Ehrard and Wiesinger) began to appear at Königsberg in 1839, and was translated into English in 4 vols. (Edinburgh, 1847-1849). He had prepared for it by his other works, Die Achtheit d. vier Kanon. Evangelien (1823), Ein Wort über tieferen Schriftsinn (1824) and Die biblische Schriftauslegung (1825).

OLTENITZA (Olenita), a town of Rumania, on the left bank of the river Argesh, 33 m. from its outflow into the Danube, and at a terminus of a branch railway from Bucharest. Pop. (1900) 5801. The principal trade is in grain, timber (floated down the Argesh) and fish. Lake Greca, famous for its carp, lies 10 m. E. and has an area of about 45 sq. m. Its waters reach the Danube through a network of streams, marshes and mires. Oltentiza is the ancient Constantioli, which was the seat of the first bishopric established in Dacia. In the Crimean War the Turks forced the river at this point and inflicted heavy losses on the Russians.

OLUSTEE, a village of Baker county, Florida, U.S.A., in the precinct of Olustee, about 46 m. W. by S. of Jacksonville. Pop. of the precinct (1910) 466. The village is served by the Seaboard Air Line. The battle of Olustee, or Ocean Pond (the name of a small body of water in the vicinity), one of the most sanguinary engagements of the Civil War in proportion to the numbers engaged, was fought on the 20th of February 1864, about 2 m. east of Olustee, between about 5500 Federal troops, under General Truman Seymour (1824-1897), and about 5400 Confederates, under General Joseph Finegan, the Federal forces being decisively defeated, with a loss, in killed and wounded, of about one-third of their number, including several officers. The Confederate losses, in killed and wounded, were about 940.

OLYBRIUS, Roman emperor of the West from the 11th of July to the 23rd of October 472, was a member of a noble family and a native of Rome. After the sack of the city by Genseric
(Geiseric) in 455, he fled to Constantinople, where in 464 he was made consul, and about the same time married Placidia, daughter of Valentinian III. and Eudoxia. This accorded Genesic, whose son Huneric had married Eudocia, the elder sister of Placidia, the opportunity of claiming the empire of the West for Olybrius. In 472 Olybrius was sent to Italy by the emperor Leo to assist the emperor Anthemius against his son-in-law Ricimer, but, having entered into negotiations with the latter, was himself proclaimed emperor against his will, and on the murder of his rival ascended the throne unopposed. His reign was as uneventful as it was brief.

See Gibbon, *Decline and Fall*, ch. xxxvii.: J. B. Bury, *Later Roman Empire*.

**OLYMPIA**, the scene of the famous Olympic games, is on the right or north bank of the Alpheus (mod. Ruplia), about 11 m. E. of the modern Pyrogos. The course of the river is here from E. to W., and the average breadth of the valley is about 1 ft. At this point a small stream, the ancient Cladeus, flows from the north into the Alpheus. The area known as Olympia is bounded on the west by the Cladeus, on the south by the Alpheus, on the north by the low heights which shut in the Alpheus valley, and on the east by the ancient racetracks. One group of the northern heights terminates in a conical hill, about 400 ft. high, which is cut off from the rest by a deep cleft, and descends abruptly on Olympia. This hill is the famous *Cronion*, sacred to Cronus, the father of Zeus.

The natural situation of Olympia is, in one sense, of great beauty. When Lysias, in his *Olympicae* (spoken here), calls it "the fairest spot of Greece," he was doubtless thinking also—or perhaps chiefly—of the masterpieces which art, in all its forms, had contributed to the embellishment of this national sanctuary. But even now the praise seems hardly excessive to a visitor who, looking eastward up the fertile and well-watered valley of Olympia, sees the snow-crowned peaks of Parnassus and Lycaon rising in the distance. The valley, at once spacious and definite, is a natural precinct, and it is probable that no artificial boundaries of the Altis, or sacred grove, existed until comparatively late times.

**History.**—The importance of Olympia in the history of Greece is religious and political. The religious associations of the place date from the prehistoric age, when, before the states of Elis and Pisa had been founded, there was a centre of worship in this valley which is attested by early votive offerings found beneath the Heraeum and an altar near it. The earliest extant building on the site is the temple of Hera, which probably dates in its original form from about 1000 B.C. There were various traditions as to the origin of the games. According to one of them, the first race was that between Pelops and Oenomaus, who used to challenge the suitors of his daughter Hippodameia and then slay them. According to another, the festival was founded by Hercules, either the well-known hero or the Idaean Dactyl of that name. The control of the festival belonged in early times to Pisa, but Elis seems to have claimed association with it. Sixteen women, representing eight towns of Elis and eight of Pisa, wove the festal robe for the Olympic Hera. Olympia thus became the centre of an amphictyony (q.v.), or federal league under religious sanction, for the west coast of the Peloponnesus, as Delphi was for its neighbours in northern Greece. It suited the interests of Sparta to join this amphictyony; and, before the regular catalogue of Olympic victors begins in 776 B.C., Sparta had formed an alliance with Elis. Aristotle saw in the temple of Hera at Olympia a bronze disk, recording the traditional laws of the festival, on which the name of Lycurgus stood next to that of Iphitus, king of Elis. Whatever may have been the age of the disk itself, the relation which it indicates is well attested. Elis and Sparta, making common cause, had no difficulty in excluding the Pisatans from their proper share in the management of the Olympic sanctuary. Pisa had, indeed, a brief moment of better fortune, when Phidon of Argos celebrated the 28th Olympiad under the presidency of the Pisatans. This festival, from which the Eleans and Spartans were excluded, was afterwards struck out of the official register, as having no proper existence. The destruction of Pisa (before 377 B.C.) by the combined forces of Sparta and Elis put an end to the long rivalry. Not only Pisa, but also the district of Triphylia to the south of it, became dependent on Elis. So far as the religious side of the festival was concerned, the Eleans had an unquestioned supremacy. It was at Elis, in the gymnasion, that candidates from all parts of Greece were tested, before they were admitted to the athletic competitions at Olympia. To have passed through the training (usually of ten months) at Elis was regarded as the most valuable preparation. Elean officials, who not only adjudged the prizes at Olympia, but decided who should be admitted to compete, marked the national aspect of their functions by assuming the title of *Hellenodiceae*.

Long before the overthrow of Pisa the list of contests had been so enlarged as to invest the celebration with a Panhellenic character. Exercises of a Spartan type—testing endurance and strength with an especial view to war—had almost exclusively occupied the earlier programme. But as early as the 25th Olympiad—i.e., several years before the interference of Phidon on behalf of Pisa—the four-horse chariot-race was added. This was an invitation to wealthy competitors from every part of the Hellenic world, and was also the recognition of a popular or spectacular element, as distinct from the skill which had a merely athletic or military interest. Horse-races were added later. For such contests the *hippodrome* was set apart. Meanwhile the list of contests on the old racetrack, the *stadium*, had been enlarged. Besides the foot-race in which the course was traversed once only, there were now the *diaulos* or double course, and the "long" foot-race (dolichos). Wrestling and boxing were combined in the *pentaathlon*. Leaping, quoit-throwing, javelin-throwing, running and wrestling were combined in the *pentathlon*. The festival was to acquire a new importance under the protection of the Spartans, who, having failed in their plans of actual conquest in the Peloponnesus, sought to gain at least the hegemony (acknowledged predominance) of the peninsula. As the Eleans, therefore, were the religious supervisors of Olympia, so the Spartans aimed at constituting themselves its political protectors. Their military strength—greatly superior at the time to that of any other state—enabled them to do this. Spartan arms could enforce the sanction which the Olympian Zeus gave to the oaths of the amphictyontes, whose federal bond was symbolized by common worship at his shrine. Spartan arms could punish any violation of that "sacred truce" which was indispensable if Hellenes from all cities were to have peaceable access to the Olympic festival. And in the eyes of all Dorians the assured dignity thus added to Olympia would be enhanced by the fact that the protectors were the Spartan Hercalidae.

Olympia entered on a new phase of brilliant and secure existence as a recognized Panhellenic institution. This phase may be considered as beginning after the establishment of Elean supremacy in 377 B.C. And so to the last Olympiad always remained a central expression of the Greek ideas that the body of man has a glory as well as his intellect and spirit, that body and mind should alike be disciplined, and that it is by the harmonious discipline of both that men best honour Zeus. The significance of Olympia was larger and higher than the political fortunes of the Greeks who met there, and it survived the overthrown of Greek independence. In the Macedonian and Roman ages the temples and contests of Olympia still interpreted the ideal at which free Greece had aimed. Philip of Macedon and Nero are, as we shall see, among those whose names have a record in the Alis. Such names are typical of long series of visitors who paid homage to Olympia. According to Cedrenus, a Greek writer of the 11th century (Σωφολος Ισορρόιας, i. 346), the Olympic festival must be held after A.D. 393, the first year of the 293rd Olympiad. The list of Olympic victors begins in 776 B.C. with Coroebus of Elis, closes with the name of an Armenian, Varastad, who is said to have belonged to the race of the Arsacidae. In the 5th century the desolation of Olympia had set in. The chryselephantine statue of the Olympian Zeus, by Phidon, was carried to Constantinople, and perished in a great fire, A.D. 476.
OLYMPIA

The Olympian temple of Zeus is said to have been dismantled, either by the Goths or by Christian zeal, in the reign of Theodosius II. (A.D. 402-450). After this the inhabitants converted the temple of Zeus and the region to the south of it into a fortress, by constructing a wall from materials found among the ancient buildings. The temple was probably thrown down by earthquakes in the 6th century A.D.

Excavations.—The German excavations were begun in 1875. After six campaigns, of which the first five lasted from September to June, they were completed on the 20th of March 1881. The result of these six years' labours was, first, to strip off a thick covering of earth from the Altis, the consecrated precinct of the Olympian Zeus. This covering had been formed, during some twelve centuries, partly by clay swept down from the Cronion, partly by deposit from the overflows of the Cladeus. The coating of earth over the Altis had an average depth of no less than 16 ft.

The work could not, however, be restricted to the Altis. It was necessary to dig beyond it, especially on the west, the south and the east, where several ancient buildings existed, not included within the sacred precinct itself. The complexity of the task was further increased by the fact that in many places early Greek work had later Greek on top of it, or late Greek work had been overlaid with Roman. In a concise survey of the results obtained, it will be best to begin with the remains external to the precinct of Zeus.

I. REMAINS OUTSIDE THE ALTIS

A. West Side.—The wall bounding the Altis on the west belongs probably to the time of Nero. In the west wall were two gates, one at its northern and the other at its southern extremity. The latter must have served as the processional entrance. Each gate was θύρα, having before it on the west a colonnade consisting of a row of four columns. There is a third and smaller gate at about the middle point of the west wall, and nearly opposite the Pelopion in the Altis.

West of the west Altis wall, on the strip of ground between the Altis and the river Cladeus (of which the course is roughly parallel to the west Altis wall), the following buildings were traced. The order in which they are placed here is that in which they succeed each other from north to south.

1. Just outside the Altis at its north-west corner was a Gymnasion. A large open space, not regularly rectangular, was enclosed on two sides—possibly on three—by Doric colonnades. On the south it was bordered by a portico with a single row of columns in front; on the east by a double portico, more than a stadium in length (220 yds.), and serving as a racetrack for practice in bad weather. At the south-east corner of the gymnasium, in the angle between the south and the east portico, was a Corinthian doorway, which a double row of columns divided into three passages. Immediately to the east of this doorway was the gate giving access to the Altis at its north-west corner. The gymnasium was used as an exercise ground for competitors during the last month of their training.

2. Immediately adjoining the gymnasium on the south was a Palaestra, the place of exercise for wrestlers and boxers. It was in the form of a square, of which each side was about 70 yds. long, enclosing an inner building surrounded by a Doric colonnade. Facing this inner building on north, east and west were rooms of different sizes, to which doors or colonnades gave access. The chief entraces to the palaestra were at south-west and south-east, separated by a double colonnade which extended along the south side.

3. Near the palaestra on the south a Byzantine church forms the central point in a complex group of remains. (a) The church itself occupies the site of an older brick building, which is perhaps a remnant of the "workshop of Phidias" seen by Pausanias. (b) North of the church is a square court with a well in the middle, which Hellenistic age. (c) West of this is a small circular structure, enclosed by square walls. An altar found (in situ) on the south side of the circular enclosure shows by an inscription that this was the Heroum, where worship of the heroes was practised down to a late period. (d) East of the court stood a large building, of Roman age at latest, arranged round an inner hall with colonnades. These buildings probably formed the Theocoleon, house of the priest. (e) There is also a long and narrow building on the south of the Byzantine church. This may have been occupied by the skopelis, those alleged "descendants of Phidias" (Pausanias v. 14), whose hereditary privilege it was to keep the statue of Zeus clean. The so-called "workshop of Phidias" (see a) evidently owed its preservation to the fact that it continued to be used for actual work,
OLYMPIA

and the adjacent building would have been a convenient lodging for the artists.

4. South of the group described above occur the remains of a large building shown by its inscription to be the Leonidaeum, dedicated by an Elean named Leonidas in the 4th century B.C., and probably intended for the reception of distinguished visitors during the games, such as the heads of the special missions from the various Greek cities. It is an oblong, of which the north and south walls only remain, and it measures 250 by 157 yds.

Its orientation differs from that of all the other buildings above mentioned, being not from N. to S., but from W.S.W. to E.N.E. Externally it is an Ionic peristyle, enclosed suites of rooms, large and small, grouped round a small interior Doric peristyle. In Roman times it was apparently a tribunal or council house, a judicial building (apparently) four quarters, each having an atrium with six or four columns. Two existing traces within the exterior porticoes on north, west and east indicate much carriage traffic.

5. The Colonnade—Although the limits of the Altis on the south (i.e. on the side towards the Alpheus) can be traced with approximate accuracy, the precise line of the south wall becomes doubtful after we have advanced a little more than one-third of the distance from the west to the east end of the south side. The middle and eastern portions of the south side were places at which architectural changes, large or small, were numerous down to the latest times, and where the older buildings met with scant mercy.

1. The Council Hall (Bouleuterion, Paus. vii. 22) was just outside the Altis, nearly at the middle of its south wall. It comprised two separate Doric buildings of different dates but identical form, viz., oblong, having a single row of columns dividing the length into two parts, the eastern (or outer) a triple colonnade. The orientation of each was from west-south-west to east-north-east, one being south-south-east of the other. In the space between stood a small square building. In front, on the east, was a portico extending along the front of the three buildings, and east-long was a large central raised vestibule or fore-hall, enclosed by a colonnade. This bouléuterion would have been available on all occasions when Olympia became the scene of conference or debate between the representatives of different states—whether the subject was properly police or political, religious or military, connected directly or indirectly with the administration of the sanctuary and festival. Two smaller Hellenic buildings stood immediately west of the bouléuterion. The more northerly of the two opened on the Altis. Their purpose is unknown by reason of the want of a tradition.

2. Close to the bouléuterion on the south, and running parallel with it from south-west by west to north-east by east, was the South Colonnade, a late but handsome structure, closed on the north side, open on the south side, and cut into the line from south to north of the Stadium. It was Doric; the interior row of columns Corinthian. It was used as a promenade, and as a place from which to view the festal processions as they passed towards the stadium.

3. East of the bouléuterion was a triumphal gateway of Roman age, with triple entrance, the central being the widest, opening on the Altis from the south. North of this gateway, but at a somewhat greater distance, was a temple building of similar kind to that in the Altis. It was Doric; the interior row of columns Corinthian. It was used as a promenade, and as a place from which to view the festal processions as they passed towards the stadium.

C. East Side.—The line of the east wall, running due north and south, can be traced from the north-east corner of the Altis down about three-fifths of the east side, where it breaks off at the remains known as "Zeus' house." These are the first which claim attention on the east side.

1. To the south-east of the Altis is a building of 4th-century date and of uncertain purpose. It was afterwards absorbed into a Roman house which projected beyond the Altis on the east, the south part of which continued the east wall of the Altis. A piece of leaved water-pipe found in the house bears NER. AVG. Only a Roman master could have dealt thus with the Altis, and with a building which stood within its sacred precinct. It cannot be described here, for the al fresco painting in the English Gymnasium was well done, and the site to the Altis—was that occupied by Nero when he visited Olympia. Later Roman hands again enlarged and altered the building, which perhaps may have been used for the reception of Roman guests.

2. Following northwards the line of the east wall, we reach at the north-east corner of the Altis the entrance to the Stadium, which extends east of the Altis in a direction from west-south-west to east-north-east, and was probably constructed about 70 B.C. The line of the stadium relatively to the Altis was due simply to the necessity of obeying the conditions of the ground, here determined by the curve of the low-lying slopes which bound the valley on the north. The Greek builders had remarked that this line was best for the assemblage of all essential points. Low embankments had originally been built on west, east and south, the north boundary being formed by the natural slope of the hill. These were afterwards covered over, and the colonnades were built. The stadium was an oblong, about 224 yds. in length by 55 in breadth. There were no artificial seats. It is computed that from 40,000 to 45,000 spectators could have found sitting-room, though it is hardly probable that such a number was ever reached. The exact length of the Stadium was 621 yds. or 192-27 metres—an important result, as it determines the Olympic foot to be 3-204 metre or a little more than an English foot (1-05). In the Heraeum at Olympia, it may be remarked, the unit adopted was not this Olympic foot, but an older one of 2-97 metre, and in the temple of Zeus an Attic foot of 1-08 English in a wall used. The starting-point and the goal in the Stadium were marked by limestone thresholds. Provision for drainage was made by a channel running round the enclosure. The Stadium was used not only for foot-races, but for boxing, wrestling, leaping, quadrennial chariot-races, the Olympic foot being thus simply the length of the hippodrome, or 770 metres or 4 Olympic stadia.

D. North Side.—If the northern limit of the Altis, like the west, south and east, had been traced by a boundary wall, this would have had the effect of excluding from the precinct a spot so sacred as the Cronion, "Hill of Cronus," inseparably associated with the oldest worship of Zeus at Olympia. It seems therefore unlikely that any such northern boundary wall ever existed. But the line of the wall of Pisistratus (whether it was a wall or a fence, as seems probable) would have marked the remains of a wall running from east to west immediately north of the treasurers' houses (see below), which it was designed to protect against the descent of earth from the Cronion just above. This wall, or at least its fragment in the area of about A.D. 157, the main water-channel constructed by Herodes Atticus, has been traced accurately, and having now surveyed the chief remains external to the sacred precinct on west, south, east and north, we proceed to notice those which have been traced within it.

II.—REMAINS WITHIN THE ALTIS

The form of the Altis, as indicated by the existing traces, is not regularly rectangular. The length of the west side, where the line of the stadium is left out, is 2307 yds., or 6940.5 metres, and that of the east side, 215 yds., or 650.5 metres. The sides of the north and south are about equal, and are 880 yds., or 2681.5 metres, each. The area of the Altis is about 2,053,000 square yards, or 1,900,200 square metres. Its dimensions were stated in a papyrus of the 1st century B.C. to be three-quarters an Attic stade or 3000 stadia, and in another to be 297 metres, or 1000 stadia.

The remains or sites within the Altis may conveniently be classed in three main groups, viz.—(A) the chief centres of religious worship; (B) the Prytaneum, with the administrative buildings or offices; (C) the treasurers' houses, with the stadium.

A. Chief Centres of Religious Worship.—1. There are traces of an altar near the Heraeum which was probably older than the great Altis of Zeus, the original centre of worship. The great altar of Zeus was of elliptic form, 3000 stadia, and was cut into three sections by a double row of columns. The central partition, which was the widest, consisted of three sections. The west section contained the throne and image of the Olympian Zeus. The middle section, next to the central, contained a table and stelae. Here, probably, the wreaths were presented to the victors.
OLYMPIA

The third or easternmost section was open to the public. This temple was most richly adorned with statues and reliefs. On the east front were represented in twenty-one colossal figures the moment before the contest between Oenomaus and Pelops. The west front exhibited the fight between Lapithae and centaurs. On the pediments of the temple, the two pediments were made by Paionius and Alcamenes is now generally supposed to be an error. The Twelve Labours of Heracles were depicted on the metopes of the prodomos and opisthodomos. These carvings were so fine that it was difficult to determine with certainty all the essential features of the composition. It was near this temple, at a point about 38 yds. E.S.E. from the south-east angle, that the explorers found the statue of a flying goddess of victory—the Nike (victory) of Phidias. This was the earliest example of the nude female figure in sculpture. The temple was raised on two steps. It is probably the oldest of extant Greek temples, and may date from about 1000 B.C. It has colonnades of six columns each at east and west, and of sixteen each (counting the porches) at north and south. It is one of the very few temples in the Greek world to have retained the form of the temple of Zeus, and, while resembling it in general plan, differed from it by its singular length relatively to its breadth. When Pausanias saw it, one of the two columns of the opisthodomos (at the rear) of the cella wall of the temple had fallen, and the entablature above the columns was of wood covered with terracotta. The cella—divided, like that of Zeus, into three partitions by a double row of columns—had four "tongue-walls," or small squares, which were ornamented with monolithic half-columns, one on each side from the south wall. The cella was formed by four steps, and the pediments were placed at the angles, and the four pediments were formed in the shape of half-domes. The pediments were decorated with statues of the gods and goddesses, from the treasuries of the Megarians.

2. The Philippine stood near the north-west corner of the Altis, or sacred area, west of the Heraeum. It was dedicated by Philip of Macedonia, after his victory at Chaeronea (338 B.C.). As a thank-offering for the overthrow of Greek freedom, it might seem strangely placed in the Olympian Altis. But it is, in fact, only another illustration of the manner in which Philip's position and power enabled him to place a decent disguise on the real nature of the change. Without risking any revolt of Hellenic feeling, his Macedonian rule was represented as a new kind of worship, in which the gods were worshipped with a benefit to the highest practical value. Olympia further possessed several fountains, enclosed by round or square walls.
OLYMPIA—OLYMPUS 97

chiefly in connexion with the buildings outside the Altis. The drainage of the Altis followed two main lines. One, for the west part, passed from the south-west angle of the Heraeum to the south portico outside the south Altis wall. The other, which served for the treatment of sewage, passed in front of the Porch of Echo parallel with the line of the east Altis wall.

See the official Die Ausgrabungen zu Olympia (5 vols., 1875-1881); Laloux and Monceaux, Restauration de l'Olympie (1880); Curtius and Olympos, Olympos (1884), and Olympos, Ausgrabungen zu Olympia. (1.) "Topographie und Geschichte," II. "Bautenkämmer," III. "Bildwerke in Stein und Ton" (Treu), IV. "Bronzen" (Furtwängler), V. "Inschriften" (Dittenberger and Furtgeld).

(R. C. J.; E. Gr.)

OLYMPIA, the capital of the state of Washington, U.S.A., and the county-seat of Thurston county, on the Des Chutes river, one of the main branches of the Willamette and Budd's Inlet, at the head of Puget Sound, about 30 m. S.S.W. of Seattle. Pop. (1890) 4068; (1900) 3863, of whom 301 were foreign-born; (1910; U. S. census) 6996. It is served by the Northern Pacific and the Port Townsend Southern railways, and by some portions of the Pacific Coast line and trains running from Alaska to Portland and along the Pacific coast. Budd's Inlet is spanned here by a wagon bridge and a railway bridge. Among the prominent buildings are the Capitol, which is constructed of native sandstone and stands in a park of considerable beauty, the county court-house, St Peter's hospital, the governor's mansion, and the city hall. The state library is housed in the Capitol. At Tumwater, the oldest settlement (1845) on Puget Sound, about 2 m. S. of Olympia, are the Tumwater Falls of the Des Chutes, which provide good water power. The city's chief industry is the cutting, sawing and dressing of lumber obtained from the forests. Olympia oysters are well known in the Pacific coast region; they are obtained chiefly from Oyster Bay, Skookum Bay, North Bay and South Bay, all near Olympia. Olympia was laid out in 1851, became the capital of Washington in 1853, and was chartered as a city in 1860.

OLYMPIAD, in Greek chronology, a period of four years, used as a method of dating for literary purposes, but never adopted in modern times as a day-by-day method. The four years were reckoned from one of the religious games in Olympic to another, the first Olympiad beginning with 776 B.C., the year of Coroebus, the first victor in the games after their suspension for 86 years, the last with A.D. 304, when they were finally abolished during the reign of theodosius the Great. The system was first regularly used by the Sicilian historian Timaeus (352-250 B.C.).

OLYMPIAS, daughter of Neoptolemus, king of Epirus, wife of Philip II., of Macedon, and mother of Alexander the Great. Her father claimed descent from Pyrrhus, son of Achilles. It is said that Philip fell in love with her in Samothrace, where they were both being initiated into the mysteries (Plutarch, Alexander, i.). The marriage took place in 350 B.C., shortly after Philip's accession, and Alexander was born in 356 B.C. The fickleness of Philip and the jealousy of his father, both interested in young Pyrrhus, was a source of considerable inconvenience, which became complete when Philip married a new wife, Cleopatra, in 337 B.C. Alexander, who sided with his mother, withdrew, along with her, into Epirus, whence they both returned in the following year, after the assassination of Philip, which Olympias is said to have connived at. During the absence of Alexander, with whom she regularly corresponded on public as well as domestic affairs, she had great influence, and by her arrogance and ambition caused such trouble to the regent Antipater that on Alexander's death (329) she found it prudent to withdraw into Epirus. Here she remained until 317, when, allaying herself with Polyperchon, by whom her old enemy had been succeeded in 319, she took the field with an Epirite army; the opposing troops at once declared in her favour, and for a short period Olympia was mistress of Macedonia. Cassander, Antipater's son, hastened from Paeonieus and, after an obstinate siege, took up the surrender of Pyrrhus, where she had taken refuge. One of the terms of the capitulation had been that her life should be spared; but in spite of this she was brought to trial for the numerous and cruel executions of which she had been guilty during her short lease of power. Condemned without a hearing, she was put to death (316) by the friends of those whom she had slain, and Cassander is said to have denied her remains the rites of burial.

See Plutarch, Alexander, 9, 30; Justin, vii. 6, ix. 7, xiv. 5, 6; Arrian, Anat. vii. 12; Diod. Sic. xviii. 49-65, xix. 11-51; also the articles ALEXANDER III. THE GREAT AND MACEDONIAN EMPIRE.

OLYMPIODORUS, the name of several Greek authors, of whom the following are the most important. (1) An historical writer (5th century A.D.), born at Thebes in Egypt, who was sent on a mission to Attila by the emperor Honorius in 412, and later lived at the court of Theodosius. He was the author of a history (Ἰορνυον τον αντικουρασμον) in 22 books of the Western Empire from 407 to 425. The original is lost, but an abstract is given by Photius, according to whom he was an alchemist (πουρις). A MS. treatise on alchemy, reputed to be by him, is preserved in the National Library at Paris, and was printed with a translation by F. E. M. Berthelot in his Collection des alchimistes grecs (1857-1884). (2) A Periapatetic philosopher (5th century A.D.), brother of Tranianus. He lived at Alexandria and lectured on Aristotle with considerable success. His best-known pupil was Proclus, to whom he wished to betroth his daughter. (3) A Neoplatonist philosopher, also of Alexandria, who flourished in the 6th century of our era, during the reign of Justinian. He was, therefore, a younger contemporary of Damascius, and seems to have carried on the Platonic tradition after the closing of the Athenian School in 520, at a time when the old pagan philosophy was at its last ebb. His philosophy is in close conformity with that of Damascius, and, apart from great lucidity of expression, shows no striking features. He is, however, important as a critic and a commentator, and preserved much that was valuable in the writings of Iamblichus, Damascius and Sianus. He made a close and intelligent study of the dialogues of Plato, and his notes, formulated and collected by his pupil (τὸ ἐφικμαὶ Ὀλυμπιάδορος τοῦ μαθῆτῆς Φασσαῦνος), are extremely valuable. In one of his commentaries he makes the interesting statement that the Platonic tradition had not been interrupted by the numerous confiscations it had suffered. Zeller points out that this refers to the Alexandrian, not to the Athenian, succession; but internal evidence makes it clear that he does not draw a hard line of demarcation between the two schools. The works which have been preserved are a life of Plato, an attack on Strato and Scholia on the Phaedo, Alcibiades I., Philebus and Gorgias. (4) An Aristotelian who wrote a commentary on the Meteorologia of Aristotle. He also lived at Alexandria in the 6th century, and from a reference in his work to a comet must have lived after A.D. 564. But Zeller (ii. 2, p. 582, n. 1) maintains that he is identical with the commentator on Plato (2, above) in spite of the late date of his death. His work, like that of Simplicius, endeavours to reconcile Plato and Aristotle, and refers to Proclus with reverence. The commentary was printed by the Aldine Press at Venice about 1500.

OLYMPUS, the name of many mountains in Greece and Asia Minor, and of the habitation of the gods, and also a city and a personal name.

I. Of the mountains bearing the name the most famous is the lofty ridge on the borders of Thessaly and Macedonia. The river Peneus, which drains Thessaly, finds its way to the sea through the great gorge of Tempe, which is close below the south-eastern end of Olympus and separates it from Mount Ossa. The highest peak of Olympus is nearly 10,000 ft. high; it is covered with snow for great part of the year. Olympus is a mountain of massive appearance, in many places rising in tremendous precipices broken by vast ravines, which is the broad summit. The lower parts are densely wooded; the summit is naked rock. Homer calls the mountain Ἄεας, Ἀιας, πάλαις Ἀιας, χορέσεις; the epithets Θεοκόρλος, Πνεύμονας, φανέρος, ἀφαίρεσις and ἀφαίρων are used by other poets. The modern name is Άγιος, a dialectic form of the ancient word.

The peak of Mount Lycaeus in the south-west of Arcadia was called Olympus. East of Olympus, on the north bank of the Alpheus, was a hill bearing this name; beside Sellasia in Laconia another. The name was even commoner in Asia
is spoken of as a city of the first rank (πελώς μισάρας), and the league included thirty-two cities. When war broke out between Philip and Athens (357), Olynthus was at first in alliance with Philip. With alarm at the growth of his power, it concluded an alliance with Athens, but in spite of all the efforts of the latter state, and of its great orator Demosthenes, it fell before Philip, who razed it to the ground (348).

The history of the confederacy of Olynthus illustrates at once the strength and the weakness of that movement towards federation which is one of the most marked features of the later stages of Greek history. The strength of the movement is shown both by the duration and by the extent of the Chalcidian League. It lasted for something like seventy years; it survived defeat and temporary dissolution, and it embraced upwards of thirty cities. Yet, in the end, the centrifugal forces proved stronger than the centripetal; the sentiment of autonomy stronger than the sentiment of union. It is clear that Philip's victory was mainly due to the spirit of dissidence within the league itself, just as the victory of Sparta had been (cf. Diod. xvi. 53, 2 with Xen. Hell. v. 2, 24). The mere fact that Philip captured all the thirty-two towns without serious resistance is sufficient evidence of this. It is probable that the strength of the league was more seriously undermined by the policy of Athens than by the actions of Sparta. At the expense of Olynthus, shortly before Philip's accession, must have finally divided the Greek interest north of the Aegean in the struggle with Macedon.

AUTHORITIES.—The chief passages in ancient literature are the Olynthiac Orations of Demosthenes, and Xenophon, Hell. v. 2. See E. A. Freeman, History of Federal Government, ch. iv.; A. H. J. Greenidge, Handbook of Greek Constitutional History (1896), p. 226; Xen. Hell. v. 2, 30; Xen. Mem., p. 184; G. Gilber, Griechische Staatsälterbörmer, vol. ii. pp. 197-198. The view taken by all these authorities as to the date of the formation of the Confederacy of Olynthus differs widely from that put forward above. Freeman and Greenidge suppose the league to have originated in 382, read in 392, Hicks (Manual of Greek Inscriptions, No. 74) before 390. The decisive test is the numismatic one. There are coins of the league in the British Museum which are earlier than 400, and one in the possession of Professor Oman, of Oxford, which he and Mr. Head are disposed to think may be as early as 415-420. (E. M. W.)

OMAGH, a market town and the county town of county Tyrone, Ireland, on the river Strule, 120½ m. N.W. by N. from Dublin by the Londonderry line of the Great Northern railway, here joined by a branch from Enniskillen. Pop. (1901) 4780. The greater part of the town is picturesquely situated on a steep slope above the river. The milling and linen industries are carried on, and monthly fairs are held. The Protestant church has a lofty and handsome spire, and the Roman Catholic church stands well on the summit of a hill. A castle, of which there are scanty remains, was of sufficient importance to stand siege in 1569 and 1641, being rebuilt after its total destruction in the first case. The town is governed by an urban district council.

OMAGUAS, OMANAS or CAMBEVAS (flat-heads), a tribe of South American Indians of the Amazon valley. Fabulous stories about the wealth of the Omagus led to several early expeditions into their country, the most famous of which were those of George de Sires in 1536, of Philip von Hutten in 1541, of Pedro de Ursua, and of Father Imago, and of Father Zapata in 1586. In 1687 Father Fritz, ‘‘apart from the Omagus,’’ established some forty mission villages. The Omagus are still numerous and powerful around the head waters of the Jakupa and Uapetes.

OMAHA, the county-seat of Douglas county and the largest city in Nebraska, U.S.A., situated on the W. bank of the Missouri river, about 20 m. above the mouth of the Platte. Pop. (1880) 36,918; (1890) 60,356; (1900) 102,555; of whom 23,552 (comprising 5322 Germans, 3968 Swedes, 2430 Danes, 2170 Bohemians, 2164 Irish, 1706 English, 1147 English Canadians, and 1147 English Canadians.

These are the figures given in Census Bulletin 71, Estimates of Population, 1904, 1905, 1906 (1907), and are the arithmetical mean between the figures for 1880 and those for 1900, those of the census of 1890 being 140,562; these are submitted by the Bureau of the Census, as the 1900 census was in error. In 1910, according to the U.S. census, the population was 124,096.
99 Russians, &c.) were foreign-born and 3443 were negroes, (1860 estimate) 124,167. Originally, with Council Bluffs, Iowa, the eastern terminus of the first Pacific railway, Omaha now has outlets over nine great railway systems: the Chicago, Burlington & Quincy, the Union Pacific, the Chicago, Rock Island & Pacific, the Chicago Great-Western, the Chicago & North-Western, the Chicago, Milwaukee & St Paul, the Illinois Central, the Missouri Pacific and the Wabash. Bridges over the Missouri river connect Omaha with Council Bluffs. The original town site occupied an elongated and elevated river terrace, now given over wholly to business; behind this are hills and bluffs, over which the residential districts have extended.

Among the more important buildings are the Federal Building, Court House, a city-hall, two high schools, one of which is one of the finest in the country, a convention hall, the Auditorium and the Public Library. Omaha is the seat of Roman Catholic and Protestant Episcopal bishoprics. Among the educational institutions are a state school for the deaf (1867); the medical department and orthopaedic branch of the University of Nebraska (whose other departments are at Lincoln); a Presbyterian Theological Seminary (1891); and Creighton University (Roman Catholic, under Jesuit control). This university, which was founded in honour of Edward Creighton (d. 1874) (whose brother, Count John A. Creighton, d. 1907, gave large sums in his lifetime and about $1,250,000 by his will), was incorporated in 1879; it includes the Creighton Academy, Creighton College (1873), to which a Scientific Department was added in 1883, the John A. Creighton Medical College (1892), the Creighton University College of Law (1904), the Creighton University Dental College (1905) and the Creighton College of Pharmacy (1903). In 1909-1910 it had 120 instructors and 800 students. St Joseph's Hospital (Roman Catholic) was built as a memorial to John A. Creighton. The principal newspapers are the Omaha Bee, the World-Herald and the News. The Omaha Bee was established in 1871 by Edward Rosewater (1841-1906), who made it one of the most influential Republican journals in the West. The World-Herald (Democratic), founded in 1865 by George L. Miller, was edited by William Jennings Bryan from 1894 to 1906.

Omaha is the headquarters of the United States military department of the Missouri, and there are military posts at Fort Omaha (signal corps and station for experiments with war balloons), immediately north, and Fort Crook (infantry), 10 m. S. of the city. A carnival, the "Festival of Ak-Sar-Ben," is held in Omaha every autumn. Among the manufacturing establishments of Omaha are breweries (product valued in 1905, $1,141,424) and distilleries, silver and lead smelting and refining works, railway shops, flour and grist-mills and dairies. The product-value of its manufactures in 1900 ($43,168,866) constituted 30% of the total output of the state, not including the greater product (48.9% of the total) of South Omaha (g.r.), where the industrial interests of Omaha are largely concentrated. The factory product of Omaha was valued at $30,000,000, and the value of 8.7% of that ($2,074,244) for 1900. The net debt of the city on the 1st of May 1899 was $5,770,000; its assessed value in 1905 (about $6,681,000) was $59,740,148, and its total tax-rate was $1.73 per $100.

In 1804 Meriwether Lewis and William Clark camped on the Omaha plateau. In 1825 a licensed Indian post was established here. In 1846 the Mormons settled at "Winter Quarters"—after 1845 called Florence (pop. in 1900, 668), and in the immediate environs (6 m. N.) of the present Omaha—and by 1847 had built up camps of some 12,000 inhabitants on the Nebraska and Iowa sides of the Missouri. Compelled to remove from the Indian reservation within which Winter Quarters lay, they founded "Kanesville" on the Iowa side (which also was called Winter Quarters by the Mormons, and after 1853 was known as Council Bluffs), gradually emigrating to Utah in the years following. Winter Quarters (Florence) was deserted in 1848, but many Mormons were still in Nebraska and Iowa, and their local influence was strong for nearly a decade afterwards. Not all had left Nebraska in 1853. Speculative land "squatters" intruded upon the Indian lands in that year, and a rush of settlers followed the opening of Nebraska Territory under the Kansas-Nebraska Bill of 1854. Omaha (named from the Omaha Indians) was platted in 1854, and was first chartered as a city in 1857. It was the provisional territorial capital in 1854-1855, and the regular capital in 1855-1857. Its charter status has often been modified. Since 1857 it has been the only city of the state governed under the general charter for metropolitan cities. Prairie freighting and Missouri river navigation were of importance before the construction of the Union Pacific railway, and the activity of the city in securing the freighting interest gave her an initial start over the other cities of the state. Council Bluffs was the legal, but Omaha the practical, eastern terminus of that great undertaking, work on which began at Omaha in December 1863. The city was already connected as early as 1863 by telegraph with Chicago, St Louis, and since 1861 with San Francisco. Lines of the present great Rock Island, Burlington and North-Western railway systems all entered the city in the years 1867-1868. Meat-packing began as early as 1871, but its first great advance followed the removal of the Union stock yards south of the city in 1884. South Omaha (q.v.) was rapidly built up around them. A Trans-Mississippi Exposition illustrating the progress and resources of the states west of the Mississippi was held at Omaha in 1898. It represented an investment of $2,000,000, and in spite of financial depression and wartime, 90% of their subscriptions were returned in dividends to the stockholders.

OMAHAS, a tribe of North American Indians of Siouan stock. They were found on St Peter's river, Minnesota, where they lived an agricultural life. Owing to a severe epidemic of small-pox they abandoned their village, and wandered westward to the Niobrara river in Nebraska. After a succession of treaties and removals they are now located in a reservation in eastern Nebraska, and number some 1200.

OMALIS D'HALLOY, JEAN BAPTISTE JULIEN D' (1783-1873). Belgian geologist, was born on the 16th of February 1783 at Liège, and educated firstly in that city and afterwards in Paris. While a youth he became interested in geology, and being of independent means he was able to devote his energies to geological researches. As early as 1808 he communicated to the Journal des mines a paper entitled Essai sur la géologie du Nord de la France. He became maire of Sceuvre in 1807, governor of the province of Namur in 1815, and from 1848 occupied a place in the Belgian senate. He was an active member of the Belgian Academy of Sciences from 1816, and served three times as president. He was likewise president of the Geological Society of France in 1852. In Belgium and the Rhine provinces he was one of the geological pioneers in determining the stratigraphy of the Carboniferous and other rocks. He studied also in detail the Tertiary deposits of the Paris Basin, and ascertained the extent of the Cretaceous and some of the older strata, which he for the first time clearly depicted on a map (1847). He was distinguished as an ethnologist, and when nearly ninety years of age he was chosen president of the Congress of Pre-historic Archaeology (Brussels, 1872). He died on the 15th of January 1875. His chief works were: Mémoires pour servir à la description géologique des Pays-Bas, de la France et de quelques contrées voisines (1828); Éléments de géologie (1831, 3rd ed. 1839); Abrégé de géologie (1853, 7th ed. 1862); Des races humaines, ou éléments d'ethnographie (5th ed., 1869).

OMAN, a kingdom occupying the south-eastern coast districts of Arabia, its southern limits being a little to the west of the meridian of 55° E. long., and the boundary on the north the southern borders of El Hasa. Oman and Hasa between them occupy the eastern coast districts of Arabia to the head of the Persian Gulf. The Oman-Hasa boundary has been usually drawn north of the promontory of El Katt. This is, however, incorrect. In 1870 Katt was under Wahhabi rule, but in the year 1871 Turkish assistance was requested to aid the settlement of a
family quarrel between certain Wahhabi chiefs, and the Turks thus obtained a footing in Katr, which they have retained ever since. Turkish occupation (now firmly established throughout El Hasa) includes Katif (the ancient Gerra), and El Bidia on the coast of Katr. But the pearl fisheries of Katr are still under the protection of the chiefs of Bahrein, who are themselves under British protection. The pact of Katr (Sheikh Jasim ben Thani), instigated by the Turks, attacked Sheikh Isa of Bahrein, but his fleet of dhows was destroyed by a British gunboat, and Bahrein (like Zanzibar) has since been detached from Oman and placed directly under British protection.

Oman is a mountainous district dominated by a range called Jebel Akhdar (or the Green Mountain), which is 10,000 ft. in altitude, and is flanked by minor ranges running approximately parallel to the coast, and shutting off the harbours from the interior. They enclose long lateral valleys, some of which are fertile and highly cultivated, and traversed by narrow precipitous gorges at intervals, which form the only means of access to the interior from the sea. Beyond the mountains which flank the cultivated valleys of Semail and Tyin, to the west, there stretches the great Ruba el Khali, or Dahna, the central desert of southern Arabia, which reaches across to the continent to the borders of Yemen, isolating the pockets of the landward side just as the rugged mountain barriers shut it off from the sea. The wadis (or valleys) of Oman (like the wadis of Arabia generally) are merely torrential channels, dry for the greater part of the year. Water is obtained from wells and springs in sufficient quantity to supply an extensive system of irrigation.

The only good harbour on the coast is that of Muscat, the capital of the kingdom, which, however, is not directly connected with the interior by any mountain route. The little port of Matrah, immediately contiguous to Muscat, offers the only opportunity for penetrating into the interior by the wadi Khaza, a rough pass which is held for the sultan or imam of Muscat by the Rehbayin chief. In 1833, owing to the treachery of this chief, Muscat was besieged by a rebel army, and disaster was only averted by the guns of H.M.S. "Phiolomel." About 50 m. south of Muscat the port of Kuyat is again connected with the inland valleys by the wadi Hall, leading to the gorges of the town of Thalid, or "Devil's Gyp." Both routes give access to the wadi Tyin, which, enclosed between the mountain of El Beidich and Hallowy (from 2000 to 3000 ft. high), is the garden of Oman. Fifty miles to the north-west of Muscat this interior region may again be reached by the transverse valley of Semail, leading into the wadi Munsab, and from thence to Tyin. This is generally reckoned the easiest line for travellers. But all routes are difficult, winding between granite and limestone rocks, and abounding in narrow defiles and rugged torrent beds. Vegetation is, however, tolerably abundant—tamarisks, oleanders, kafas, euphorbias, the milk bush, thorns and acacias being the commonest and most characteristic forms of vegetable life, and pools of water are frequent. The rich oasis of Tyin contains many villages boscamed in palm groves and surrounded with orchards and fields.

In addition to cereals and vegetables, the cultivation of fruit is abundant throughout the valley. After the date, vines, peaches, apricots, oranges, mangos, melons and mulberries find special favour with the Rehbayin, who exhibit all the skill and perseverance of the Arab agriculturist of Yemen, and cultivate everything that the soil is capable of producing.

The sultan, a descendant of those Yemenite imams who consoldated Arab power in Zanzibar and on the East African coast, and raised Oman to its position as the most powerful state in Arabia during the first half of the 19th century, resides at Muscat, where his palace directly faces the harbour, not far from the British residency. The little port of Gwadar, on the Makran coast of the Arabian Sea, a station of the Persian Gulf telegraph system, is still a dependency of Oman.

OMAR (c. 381—644), in full 'OMAR IBN AL-KHAT'AB, the second of the Mahometan caliphs (see CALIPHATE, A, §§ 1 and 2). Originally opposed to Mahomet, he became later one of the ablest advisers both of him and of the first caliph, Abu Bekr. His own reign (634—644) saw Islam's transformation from a religious sect to an imperial power. The chief events were the defeat of the Persians at Kadisiya (636) and the conquest of Syria and Palestine. The conquest of Egypt followed (see Epigrams of OMAH IBN EL-ASS) and the final rout of the Persians at Nehawend (641) brought Iran under Arab rule. Omar was assassinated by a Persian slave in 644, and though he lingered several days after the attack, he appointed no successor, but only a body of six Muhajirun who should select a new caliph. Omar was a wise and far-sighted ruler and rendered great service to Islam. He is said to have built the so-called "Mosque of Omar" ("the Dome of the Rock") in Jerusalem, which contains the rock regarded by Mahomedans as the scene of Mahomet's ascent to heaven, and by the Jews as that of the proposed sacrifice of Isaac.

'OMAR KHAYYAM (in full, GHYATTHUDIN ABULPATH 'OMAR IBN IBRAHIM AL-KHAYYAMI), the great Persian mathematician, astronomer, freethinker and epigrammatist, who derived the epithet Khayyam (the tentmaker) most likely from his father's trade, was born in or near Nishapur, where he is said to have died in A.H. 575 (1173). At an early age he entered into a close friendship both with Nizam-ul-mulk and his school-fellow Hassan ibn Sabba, who founded afterwards the terrible sect of the Assassins. When Nizam-ul-mulk was raised to the rank of vizier by the Seljuk sultan Alp-Aralan (A.D. 1063—1073) he bestowed upon Hassan ibn Sabba, the dignity of a chamberlain, whilst offering a similar court office to 'Omar Khayyam. But the latter contented himself with an annual stipend which would enable him to devote all his time to his favourite studies of mathematics and astronomy. His standard work on algebra, written in Arabic, and other treatises of a similar character raised him at once to the foremost rank among the mathematicians of that age, and induced Sultan Malik-Shah to summon him in A.H. 407 (A.D. 1074) to institute astronomical observations on a larger scale, and to aid him in his great enterprise of a thorough reform of the calendar. The results of Omar's research were—a revised edition of the Zij or astronomical tables, and the introduction of the T'a'rith-i-Malkishahi or Jalali, that is, the so-called Jalalian or Seljuk era, which commences in A.H. 471 (A.D. 1079, 15th March).

Omar's great scientific fame, however, is nearly eclipsed by his still greater poetical renown, which he owes to his rubas or quatrains, a collection of about 500 epigrams. The peculiar form of the ruba—viz., four lines, the first, second and fourth of which have the same rhyme, while the third usually (but not always) remains rhymeless—was first successfully introduced into Persian literature as the exclusive vehicle for subtle thoughts on the various topics of Sufic mysticism by the sheikh Abul-Sa'id bin Alulkhair,1 but 'Omar differs in its treatment considerably from Aba Sa'id. Although some of his quatrains are purely mystical and philosophic, most of them bear quite another stamp; they are the brevity of a radical freethinker, who protests in the most forcible terms against the follies, bigotry and uncompromising austerity of the orthodox ulema, and the eccentricity, hypocrisy and wild ravings of advanced Sufis, whom he successfully combats with their own weapons, using the whole mystic terminology simply to ridicule mysticism itself. There is in this respect a great resemblance between him and Hafiz, but 'Omar is decidedly superior. He has often been called the Voltaire of the East, and cried down as materialist and atheist. As far as purity of diction, fine wit, crushing satire against a debased and ignorant clergy, and a general sympathy with suffering humanity are concerned, 'Omar certainly reminds us of the great Frenchman; but there the comparison ceases. Voltaire never wrote anything equal to 'Omar's fascinating rhapsodies in praise of wine, love and all earthly enjoyments, and his passionate denunciations of a malevolent and inexorable

---

1 Died Jan. 1049. Comp. Ech's edition of his rubas in Sittungs-
fate which dooms to slow decay or sudden death and to eternal oblivion all that is great, good and beautiful in this world. There is a touch of Byron, Swinburne and even of Schopenhauer in many of his remarks, which prove that the modern pessimist is by no means a novel creature in the realm of philosophic thought and poetical imagination.

The Leiden copy of 'Omar Khayyám's work on algebra was noticed as far back as 1742 by Gerald Meerman in the preface to his Specimen calculi fluxionum; further notices of the same work by Sorley Maclean appeared in the N. Jour. As. (1854) and in vol. xi. of the Notices et extraits des MSS. de la Bibl. roy. The complete text, together with a French translation (on the basis of the Leiden and Paris copies, the latter first discovered by M. Libri, see his Histoire des sciences mathématiques en Italie, ii. 190), is by F. Woepcke, L'Algèbre d'Omar Alchayyám (Paris, 1851). Articles on 'Omar's life and works are found in Reinaud's Géographie d'Aboul-

féda, préf., p. 101; Notices et extraits, i. 143 seq.; Garcin de Tassy, Note sur les Rubáiyát d'Omar Hâjám (Paris, 1857); René, Crit. Pers. MSS. sur le Br. Mus. 1. 546; A. Christensen, Recherches sur les Rubáiyát d'Omar Hâjém (Heidelberg, 1905); V. Zhukov-

ski's 'Omar Khayyám and the 'Wandering' Quatrains, translated from the Russian by E. D. Ross in the Journal of the Royal Asiatic Society, xxx. (1898); E. G. Browne, Literary History of Persia, ii. 246. The quatrains have been edited at Calcutta (1836) and Teheran (1857 and 1862); text and French translation by J. B. Nicolas (Paris, 1867) (very incorrect and misleading); a portion of the translation of the Persian quatrains by FitzGerald was published in London, 1859, 1872 and 1879. FitzGerald's translation has been edited with commentary by H. M. Batson (1900), and the 2nd ed. of the same (1888) by E. Heron Allen (1908). A new English version was published anonymously in 1888 by E. E. Doenecke, but the literal version in new translations and imitations has recently been supplanted (H. E.; X.).

OMBRE, a card game, very fashionable at the end of the 18th century, but now practically obsolete. The following recommendation of the game is taken from the Court Gamester, a book published in 1729 for the use of the daughters of the prince of Wales, afterwards George II:—

"The game of Ombre owes its invention to the Spaniards, and it has in it a great deal of the gravity peculiar to that nation. It is called Ombre, or The Man. It was so named as requiring thought and reflection, which are qualities peculiar to many or rather alluding to him who undertakes to play the game against the rest of the gamesters. There are no tricks in the game, the players are to guess the right deal of application, and let a man be ever so expert, he will be apt to fall into mistakes if he think of anything else or is disturbed by the conversation of them that look on. . . . It will be found the most dangerous game amongst the players who have anything in them of what we call the spirit of play."

Ombre is played by three players with a pack of 40 cards, the 8, 9, and 10 being dispensed with. The order of value of the hands is irregular, being different for trumps and suits not trumps. In a suit not trumps the order is: K, Q, Kn, ace, 2, 3, 4, 5, 6, 7; for black suits: K, Q, Kn, 7, 6, 5, 4, 3, 2. In trump suits the ace of spades, called spadille, is always a trump, and the highest one, whichever of the four suits may be trumps. The order for red trump suits is: ace of spades 7 (called manille), ace of clubs (called basto), ace (called punto), Q, K, Kn, 2, 3, 4, 5, 6. For black suit trumps: ace of spades (spadille), 2 (manille), ace (basto), K, Q, Kn, 7, 6, 5, 4, 3. There is no punto in black trumps. The three highest trumps are called maladores (or mato). The holder of them has the privilege of not following suit, except when a higher mat is played, which forces a lower one if the hand contains no other trump.

Cards are dealt round, and the receiver of the first black ace is the dealer. He deals (towards his right) nine cards, by threes, to each player. Each player puts 13 on the table of cards, as at piquet. Each deal constitutes a game. One hand against the other two, the solo player being called the Ombre. The player at the dealer's right has the first option of being Ombre, which entails two privileges: that of naming the trump suit, and that of throwing away as many of his cards as he chooses, receiving new ones in their place, as at piquet. If, with these advantages in mind, he thinks he can win against the other two hands, he says, "I ask leave," or "I play." But in this case his right-hand neighbour has the privilege of claiming Ombre for himself, providing he is willing to play his hand without drawing new cards, or, as the phrase goes, sans prendre. If, however, the other player reconsidered and decides that he will himself play without drawing cards, he can still remain Ombre. If the second player passes, the dealer in his turn may ask to play sans prendre, as above. If all three pass a new deal ensues. After the Ombre discards (if he does not play sans prendre) the two others in turn do likewise, and, if any cards are left in the stock, the last discarder may look at them (as at piquet) and the others after him. But if he does not look at them the others lose the privilege of doing so.

The manner of play is like whist, except that it is towards the right. The second and third players combine to defeat Ombre. If in the sequel Ombre makes more tricks than either of his opponents he wins. If one of his opponents makes more than Ombre the latter loses (called codille). If Ombre and one or both of his opponents make the same number of tricks the game is drawn. When Ombre makes all nine tricks he wins a role. The game is played with counters having certain values, the pool being emptied by the winner. If all pass, a counter of low value is paid into the pool by each player. If Ombre wins he takes the entire pool. If he draws he forfeits a counter to each of his opponents, which is made to the player who has the sum equal to that already in it, i.e., the pool is doubled. If either of his opponents makes the majority of the tricks (codille) Ombre and the other player pays in the pool, which itself remains untouched until the next game. When the pool is emptied each player pays in three counters.

OMDURMAN, a town of the Anglo-Egyptian Sudan, on the west bank of the Nile, immediately north of the junction of the White and Blue Niles in 15° 38' N., 32° 26' E., 2 m. N. by W. of Khartoum. Pop. (1909 census) 42,779, of whom 541 were Europeans. The town covers a large area, being over 5 m. long and 3 broad. It consists for the most part of mud huts, but there are some houses built of sun-dried bricks. Save for two or three wide streets which traverse it from end to end the town is a network of narrow lanes. In the centre facing an open space are the ruins of the tomb of the Mahdi and behind is the house in which he lived. The Khalifa's house (a two-storeyed building), the mosque, the Bel el Amara (arsenal) and other houses famed in the history of the town also face the central square. A high wall runs behind these buildings parallel with the Nile. Omdurman is the headquarters of the native traders in the Anglo-Egyptian Sudan, the chief articles of commerce being leather, cotton, gum arabic from Darfur and Kordofan. There is also an important camel and cattle market. The nearly every tribe in the Sudan is represented in the population of the city. Among the native artificers the metal workers and leather dressers are noted. The government maintains elementary and technical schools. Mission work is undertaken by various Protestant and Roman Catholic societies.

Omdurman, then an insignificant village, was chosen in 1884 by the Mahdi Mahommmed Ahmed as his capital and so continued after the fall of Khartoum in January 1885. Its growth was rapid, the Khalifa (who succeeded the Mahdi) compelling large numbers of disaffected tribesmen to live in the town under the eye of his soldiery. Here also were imprisoned the European captives of the Mahdists—notably Slatin Pasha and Father Ohrwalder. On the 2nd of September 1889 the Anglo-Egyptian army under Lord Kitchener totally defeated the forces of the Khalifa at Kerreri, 7 m. N. of the town. A marble obelisk marks the spot where the 21st Lancers made a charge. Within the enclosure of the Khalifa's house is the tomb of Hubert Howard, son of the 9th earl of Carlisle, who was killed in the house at the time of the battle. The site of the city of the city of the obelisk shell fired at the Mahdi's tomb. (See Sudan: Anglo-Egyptian.)

OMELETTE, sometimes Anglicized as "omelet," a French word of which the history is an example of the curious changes a word may undergo. The ultimate origin is Lat. lamella, diminutive of lamina, plate; this became in French lamelle, and a wrong division of to lamelle gave oalmele, oalmele, or alumelle; thence oalmelet, metathesized to oalmelet and oamelette, the form in which the word appears in the 15th and 16th centuries. The
OMEN

original meaning seems to be a pancake of a thin flat shape. Omelettes are made with eggs, beaten up lightly, with the addition of milk, flour, herbs, cheese, mushrooms, &c., according to the requirement, and cooked quickly in a buttered pan.

OMEN (a Latin word, either connected with os, mouth, or more probably with auris (Gr. ὀὖς, ear; apparently, meaning "a thing heard" or "spoken"). a sign in divination, favourable or unfavourable as the case may be (see DIVINATION, Augurs and Omens). The taking of omens may be said to be a part of all systems of divination, in which the future is predicted by means of indications of one sort or another; and tradition has thus gathered round many subjects—events, actions, colours, numbers, &c.—which are considered "omnious," an adjective which generally connotes ill-fortune.

One of the oldest and most widespread methods of divining the future, both among primitive people and among several of the civilizations of antiquity, was the reading of omens in the signs noted on the liver of the animal offered as a sacrifice to some deity. The custom is vouched for by travellers as well observed in Borneo, Burma, Uganda, and elsewhere, the animal chosen being a pig or a fowl. It constituted the most common form of divination in ancient Babylonia, where it can be traced back to the 3rd millennium B.C. Among the Etruscans the prominence of the rite led to the liver being looked upon as the trade-mark of the god. From the Etruscans it made its way to the Romans, though as we shall see it was also modified by them. The evidence for the rite among the Greeks is sufficient to warrant the conclusion of its introduction at a very early period and its persistence to a late day.

The theory upon which the rite everywhere rests is clearly the belief, for which there is an abundance of concurrent testimony, that the liver was at one time regarded as the seat of vitality. This belief appears to be of a more primitive character than the view which places the seat of life in the heart, though we are accustomed to think that the latter was the prevailing view in antiquity. The fact, however, appears to be that the prominence given to the heart in popular beliefs dates from the time when in the course of the development of anatomical knowledge the important function of the heart in animal life came to be recognized, whereas the supposition that the liver is the seat of vitality rests upon other factors than anatomical knowledge, and, being independent of such knowledge, also antedates it. Among the reasons which led people to identify the liver with the very source of life, and hence as the seat of all affections and emotions, including what to us are intellectual functions, we may name the bloody appearance of that organ. Filled with blood, it was natural to regard it as the seat of the blood, and as a matter of fact one-sixth of the entire blood of man is in the liver, while in the case of some animals the proportion is even larger. Now blood was everywhere in antiquity associated with life, and the biblical passage, Genesis ix. 3, which identifies the blood with the soul of the animal and therefore prohibits its use fairly represents the current conception both among primitive peoples as well as among those who had advanced along the road of culture and civilization. The liver being regarded as the seat of the blood, it was a natural and strong reason to identify the liver with the soul as well as with the seat of life, and therefore as the centre of all manifestations of vitality and activity. In this stage of belief, therefore, the liver is the seat of all emotions and affections, as well as of intellectual functions, and it is only when with advancing anatomical knowledge the functions of the heart and then of the brain come to be recognized that a differentiation of functions takes place which had its outcome in the assignment of intellectual activity to the brain or head, of the higher emotions and affections (as love and courage) to the heart, while the liver was degraded to the rank of being regarded as the seat of the lower emotions and affections, such as jealousy, moroseness and the like.

Hepatoscopy, or divination through the liver, belongs therefore to the primitive period when that organ summed up all vitality and was regarded as the seat of all the emotions and affections—the higher as well as the lower—and also as the seat of intellectual functions. The question, however, still remains to be answered how people came to the belief or to the assumption that through the soul, or the seat of life of the sacrificial animal, the intention of the gods could be divined. There are two theories that may be put forward. The one is that the animal sacrificed was looked upon as a deity, and that, therefore, the liver represented the soul of the god; the other theory is that the deity in accepting the sacrifice identified himself with the animal, and that, therefore, the liver as the soul of the animal was the counterpart of the soul of the god. It is true that the killing of the god plays a prominent part in primitive cults, as has been shown more particularly through the valuable researches of J. G. Frazer (The Golden Bough). On the other hand, serious difficulties arise if we assume that every animal sacrificed represents a deity; and even assuming that such a belief underlies the rite of animal sacrifice, a modification of the belief must have been introduced when such sacrifices became a common rite resorted to on every occasion when a deity was to be approached. It is manifestly impossible to assume, e.g. that the daily sacrifices which form a feature of advanced cults involved the belief of the daily slaughter of some deity, and even before this stage was reached the primitive belief of the actual identification of the god with the animal must have yielded to some such belief as that the deity in accepting the sacrifice assimilates the animal to his own being, precisely as man assimilates the food that enters into his body. The animal is in a certain sense, indeed, the food of the god.

The theory underlying hepatoscopy therefore consists of these two factors: the belief (1) that the liver is the seat of life, or, to put it more succinctly, what was currently regarded as the soul of the animal; and (2) that the liver of the sacrificial animal, by virtue of its acceptance on the part of the god, took on the same character as the soul of the god to whom it was offered. The two souls acted in accord, the soul of the animal becoming a reflection, as it were, of the soul of the god. If, therefore, one understood the signs noted on a particular liver, one entered, as it were, into the mind—as one of the manifestations of soul-life—of the deity who had assimilated the being of the animal to his own being. To know the mind of the god was equivalent to knowing what the god in question proposed to do. Hence, when one approached a deity with an inquiry as to the outcome of some undertaking, the reading of the signs on the liver afforded a direct means of determining the course of future events, which was, according to current beliefs, in the control of the gods. That there are defects in the logical process as here outlined to account for the curious rite constitutes no valid objection to the theory advanced, for, in the first place, primitive logic in matters of belief is inherently defective and even contradictory, and, secondly, the strong desire to pierce the mysterious future, forming an impelling factor in all religions—even in the most advanced of our own day—would tend to obscure the weakness of any theory developed to explain a rite which represents merely one endeavour among many to divine the intention and plans of the gods, upon the knowledge of which so much of man's happiness and welfare depends.

Passing now to typical examples, the beginning must be made with Babylonia, which is also the richest source of our knowledge of the details of the rite. Hepatoscopy in the Euphrates valley can be traced back to the 3rd millennium before our era, which may be taken as sufficient evidence for its survival from the period of primitive culture, while the supreme importance attached to signs read on the livers of sacrificial animals—usually a sheep—follows from the care with which omens derived from such inspection on occasions of historical significance were preserved as guides to later generations of priests. Thus we have a collection of the signs noted during the career of Sargon I. of Agade (c. 2800 B.C.), which in some way were handed down till the days of the Assyrian king Assur-bani-pal (668-625 B.C.). One of the chief names for the priest was bērū—literally the "inspector"—which was given to him because of the prominence of his function as an inspector of livers for the purpose of divining the intention of the gods. It is to the collections formed by these
bôrû-priests as a guidance for themselves and as a basis of instruction for those in training for the priesthood that we owe our knowledge of the parts of the liver to which particular attention was directed, of the signs noted, and of the principles guiding the interpretation of the signs.

The inspection of the liver for purposes of divination led to the study of the anatomy of the liver, and there are indeed good reasons for believing that hepatoscopy represents the starting-point for the study of animal anatomy in general. We find in the Babylonian-Assyrian omen-texts special designations for the three main lobes of the sheep's liver—the lobus dexter, the lobus sinister and the lobus caudatus; the first-named being called "the right wing of the liver," the second "the left wing of the liver," and the third "the middle of the liver." Whether the division of the lobus dexter into two divisions—(1) lobus dexter proper and (2) lobus quadratus, as in modern anatomical nomenclature—was also assumed in Babylonian hepatoscopy, is not certain, but the groove separating the right lobe into two sections—the fossa venae umbilicalis—was recognized and distinguished by the designation of "river of the liver." The two appendixes attached to the upper lobe or lobus pyramidalis, and known in ancient nomenclature as processus pyramidalis and processus papillaris, were described respectively as the "finger" of the liver and as the "offshoot." The former of these two appendixes plays especially an important part in hepatoscopy, as, and according to its shape and peculiarities, furnishes a good or bad omen. The gall-bladder, appropriately designated as "the bitter," was regarded as a part of the liver, and the cystic duct (compared, apparently, to a "penis") to which it is joined, as well as the hepatic duct (picted as an "outlet") and the ductus choleductus (described as a "yoke"), had all their special designations. The depression separating the two lower lobes from the lobus caudatus, and known as the porta hepatitis, was appropriately designated as the "crucible" of the liver. Lastly, to pass over unnecessary details, the markings of various kinds to be observed on the lobes of the livers of freshly-slaughtered animals, which are due mainly to the traces left by the subsidiary hepatic ducts and hepatic veins on the liver surface, were described as "holes," "paths," "clubs" and the like. The constantly varying character of these markings, no two livers being alike in respect, furnished a particularly large field for the fancy of the bôrû-priest.

In the interpretation of these signs the two chief factors were association of ideas and association of words. If, for example, the processus pyramidalis was abnormally small and the processus papillaris abnormally large, it pointed to a reversion of the natural order, to wit, that the servant should control the master or that the son would be above the father. A long cystic duct would point to a long reign of the king. If the gall-bladder was swollen, it pointed to an extension or enlargement of some kind. If the porta hepatitis was torn it prognosticated a plundering of the enemy's land. As among most people, a sign on the right side was favourable, but the same sign on the left side unfavourable. If, for example, the porta hepatitis was long on the right side and short on the left side, it was a good sign for the king's army; but if short on the right side and long on the left, it was unfavourable; and similarly for a whole series of phenomena connected with any one of the various subdivisions of the liver. Past experience constituted the chief factor in establishing the interpretation of signs noted. If, for example, on a certain occasion when the liver of a sacrificial animal was examined, certain events of a favourable character followed, the conclusion was drawn that the signs observed were favourable, and hence the recurrence of these signs on another occasion suggested a favourable answer to the question put to the priests. With this in view, omens given in the reigns of prominent rulers were preserved with special care as guides to the priests.

In the course of time the collections of signs and their interpretation made by the bôrû-priests grew in number until elaborate series were produced in which the endeavour was made to exhaust so far as possible all the varieties and modifications of the many signs, so as to furnish a complete handbook both for purposes of instruction and as a basis for the practical work of divination. Divination through the liver remained in force among the Assyrians and Babylonians down to the end of the Babylonian Empire.

Among the Greeks and Romans likewise it was the liver that continued throughout all periods to play the chief rôle in divination through the sacrificial animal. Blecher (De Estisticio Capita Tria, Giessen, 1905, pp. 3-22) has recently collected most of the references in Greek and Latin authors to animal divination, and an examination of these shows conclusively that, although the general term used for the inspection of the sacrificial animal was iera or iereia (i.e. "victims" or "sacred parts") in Greek, and esta in Latin, when specific illustrations are introduced, the reference is almost invariably to some sign or signs on the liver; and we have an interesting statement in Pliny (Hist. Nat. xi. § 186), furnishing the date (274 B.C.) when the examination of the heart was for the first time introduced by the side of the liver as a means of divining the future, while the lungs are not mentioned till we reach the days of Cicero (de Divinatione, i. 83). We are justified in concluding, therefore, that among the Greeks and Romans likewise the examination of the liver was the basis of hepatoscopy in the case of the sacrificial animal. It is well known that the Romans borrowed the method of hepatoscopy from the Etruscans, and, apart from the direct evidence for this in Latin writings, we have, in the case of the bronze model of a liver found near Piacenza in 1877, and of Etruscan origin, an unmistakable proof that among the Etruscans the examination of the liver was the basis of animal divination. Besides this object dating from about the 3rd century B.C., according to the latest investigator, G. Körte ("Die Bronzeleber von Piacenza," in Mitt. d. K. D. Archäol. Instituts, 1905, pp. 348-379), there are other Etruscan monuments, e.g. the figure of an Etruscan augur holding a liver in his hand as his trade-mark (Körte, tb. pl. xiv.), which point in the same direction, and indicate that the model of the liver was used as an object lesson to illustrate the method of divination through the liver. For further details the reader is referred to Thulin's monograph, Die Etruskische Disziplin, II Die Haruspizin (Gothenburg, 1906).

As for the Greeks, it is still an open question whether they perfected their method of hepatoscopy under Etruscan influence or through the Babylonians. In any case, since the Eastern origin of the Etruscans is now generally admitted, we may temporarily, at least, accept the conclusion that hepatoscopy as a method of divination owes its survival in advanced forms of culture to the elaborate system devised in the course of centuries by the Babylonian priests, and to the influence, direct and indirect, exerted by this system in the ancient world. But for this system hepatoscopy, the theoretic basis of which as above set forth falls within the sphere of ideas that belong to primitive culture, would have passed away as higher stages of civilization were reached, and as a matter of fact it plays no part in the Egyptian culture or in the civilization of India, while among the Hebrews only faint traces of the primitive idea of the liver as the seat of the soul are to be met with in the Old Testament, among which an allusion in the indirect form of a protest against the use of the sacrificial animal for purposes of divination in the ordinance (Exodus xxix. 13, 22; Leviticus lii. 4, 10, 15, &c.) to burn the processus pyramidalis of the liver, which played a particularly significant rôle in hepatoscopy, calls for special mention.

In modern times hepatoscopy still survives among primitive peoples in Borneo, Burma, Uganda, &c.

It but remains to call attention to the fact that the earlier view of the liver as the seat of the soul gave way among many ancient nations to the theory which, reflecting the growth of anatomical knowledge, assigned that function to the heart, while, with the further change which led to placing the seat of soul-life in the brain, an attempt was made to partition the various functions of manifestations of personality among the three organs, brain, heart and liver, the intellectual activity being assigned to the first-named; the higher emotions, as love
and courage, to the second; while the liver, once the master of the entire domain of soul-life as understood in antiquity, was degraded to serve as the seat of the lower emotions, such as jealousy, anger and the like. This is substantially the view set forth in the *Timaeus* of Plato (§ 72 C). The addition of the heart to the liver as an organ of the revelation of the divine will, reflects the stage which assigned to the heart the position once occupied by the liver. By the time the third stage, which placed the seat of soul-life in the brain, was reached through the further advance of anatomical knowledge, the religious rites of Greece and Rome were too deeply incrusted to admit of further radical changes, and faith in the gods had already declined too far to bring new elements into the religion. In phrenology, however, as popularly carried on as an *unofficial* cult, we may recognize a modified form of divination, co-ordinate with the third stage in the development of beliefs regarding the seat of soul and based on the assumption that this organ is—as were its predecessors—a medium of revelation of otherwise hidden knowledge.

**OMICHUND** (d. 1757), an Indian whose name is indissolubly associated with the treaty negotiated by Clive before the battle of Plassey in 1757. His real name was Amir Chund; and he was not a Bengali, as stated by Macaulay, but a Sikh from the Punjab. It is impossible now to unravel the intrigues in which he may have engaged, but some facts about his career can be stated. He had long been resident at Calcutta, where he had acquired a large fortune by providing the "investment" for the Company, and also by acting as intermediary between the English and the native court at Murshidabad. In a letter of Mr. Watts of later date he is represented as saying to the nawab (Suraj-ud-daula): "He had lived under the English protection these forty years; that he never knew them once to break their agreement, to the truth of which he took his oath by touching a Brahman's foot; and that if a lie could be proved in England upon any one, they were spit upon and never trusted." Several houses owned by him in Calcutta are mentioned in connexion with the fighting that preceded the tragedy of the Black Hole in 1756, and it is on record that he suffered heavy losses at that time. He had been arrested by the English on suspicion of treachery, but afterwards he was forward in giving help to the fugitives, and at the recapture of Calcutta he was sent by Clive to accompany Mr. Watts and Mr. Mysore to the court of Murshidabad. It seems to have been through his influence that the nawab gave reluctant consent to Clive's attack on Chandernagore. Later, when the treaty with Mir Jafar was being negotiated, he put in a claim for 5% on all the treasure to be recovered, under threat of disclosing the plot. To defeat him, two copies of the treaty were drawn up: the one, the true treaty, omitting his claim; the other containing it, to be shown to him, which Admiral Watson refused to sign, but Clive directed the admiral's signature to be appended. When the truth was revealed to Omichund after Plassey, Macaulay states (following Orme) that he sank gradually into idiocy, languished a few months, and then died. As a matter of fact, he survived for ten years, till 1767; and by his will he bequeathed £2,000 to the Foundling Hospital (where his name may be seen in the list of benefactors as "a black merchant of Calcutta") and also to the Magdalen Hospital in London. (J. S. C. O.)

**OMNIBUS** (Lat. "for all"), a large closed public conveyance with seats for passengers inside and out (see CARRIAGE). The name is derived from the Latin for "entire" or "total". It was, in the form *volutur omnibus*, first used for the conveyances known in Paris in 1826, and was taken by Shillibeer for the vehicle he ran on the Padray road in 1829. The word is also applied to a box at the opera which is shared by several subscribers, to a bill or act of parliament dealing with a variety of subjects, and in electrical engineering to the bar to which the terminals of the generators are attached and from which the current is taken off by the wires supplying the various consumers.

**OMRI**, in the Bible, the first great king of Israel after the separation of the two kingdoms of Israel and Judah, who flourished in the early part of the 9th century B.C. The dynasty of Jeroboam had been exterminated by Baasha (see Asa) at a revolt when the army was besieging the Philistines at Gibbethon, an unidentified Danite site. A quarter of a century later, Baasha’s son Elah, after a reign of two years, was slain by Zimri, captain of the chariots, in a drinking bout, and again the royal family were put to the sword. Meanwhile, the general Omri, who was at Gibbethon, was promptly elected king by the army, and Zimri himself in a short while met his death in the royal city of Tirzah. However, fresh disturbance was caused by Tibni ben Ginath (perhaps of Naphtali), and Israel was divided into rival factions. Ultimately Tibni and his brother Jerom (1 Kings xvi. 32, LXX.) were overcome, and Omri remained in sole possession of the throne. The compiler of the biblical narratives takes little interest in Omri’s work (1 Kings xvi. 15-28), and records briefly his purchase of Samaria, which became the capital of his dynasty (see SAMARIA). The inscription of Mesha throws welcome light upon his conquest of Moab (q.v.); the position of Israel during the reign of Omri’s son Ahab (q.v.) bears testimony to the success of the father; and the fact that the land continued to be known to the Assyrians down to the time of Sargon as “house of Omri” indicates the reputation which this long-known king enjoyed. (S. C. A.)

**OMSK**, town of Siberia, capital of the province of Akmolinsk, capital of eastern Siberia from 1839 to 1882, and now capital of the general-governorship of the Steppes. Pop. (1881) 31,000, (1900) 33,000. It is the seat of administration of the Siberian Cossacks, and the see of the bishop of Omsk. Situated on the right bank of the Irtysh, at its confluence with the Om, at an altitude of 285 ft., and on the Siberian railway, 1862 m. via Chelyabinsk from Moscow, and 586 m. W.S.W. of Tomsk, it is the meeting-place of the highways to middle Russia, Orenburg, and Turkestan. Steamers ply down the Irtysh and the Ob, and up the former to the Altai towns and Lake Zaisan. The climate is dry and relatively temperate, but marked by violent snow-storms and sand-storms. The average temperatures are, for the year, 31° F.; for January, 5°; for July, 68°; the annual rainfall is 12 in. The town is poorly built. Apart from the railway workshops, its industries are unimportant (steam-sawmill, tanneries); but the trade, especially since the construction of the railway, is growing. There are two yearly fairs. Omsk has a society for education, which organizes schools, kindergartens, libraries and lectures for the people. There are a corps of cadets, medical, dramatic and musical societies, and the western Siberian section of the Russian Geographical Society, with a museum.

The “fort” of Omsk was erected in 1716 to protect the block-houses on the Russian frontier, along the Ishim and the Irtysh. In consequence of the frequent incursions of the Kirghiz about the end of the 18th century, stronger earthworks were erected on the right bank of the Om; but these have now almost entirely disappeared.

**ONAGRACEAE**, in botany, an order of dicotyledons belonging to the series Myrtilloae, to which belongs also the myrtle order, Myrtaceae. It contains about 30 genera and 300 species, and occurs chiefly in the temperate zone of the New World, especially on the Pacific side. It is represented in Britain by several species of *Eplibolium* (willow-herb), *Cirsaea* (enchanter’s nightshade), and *Ludwigia*, a small perennial herb very rare in boggy pools in Sussex and Hampshire. The plants are generally herbaceous, sometimes annual, as species of *Epilobium*, *Clarkia*, *Gioedia*, or biennial,q.v. (enchanters biennium— evening primrose— or sometimes become shrubby or arborescent, as *Fuchsia* (q.v.). The simple leaves are generally entire or inconspicuously toothed, or alternate, opposite or whorled in arrangement; they are generally ovate or oval; cadaverous stipules occur in *Fuchsia, Cirsaea* and other genera. The flowers are often solitary in the leaf-axils, as in many fuchsias, *Clarkia*, &c., or associated, as in *Epilobium* and *Oenothera*, in large showy terminal spikes or racemes; in *Cirsaea* the small white or red

---

1 He is said to have reigned seven days, but the LXX. (B) in 1 Kings xvi. 15 read seven years. Further confusion is caused by the fact that the LXX. reads Zimri throughout for Omri.
flowers are borne in terminal and lateral racemes. The regular flowers have the parts in fours, the typical arrangement as illustrated by Epilobium, Oenothera and Fuchsia being as follows: 4 sepals, 4 petals, two alternating whorls of 4 stamens, and 4 inferior carpels. The floral receptacle is produced above the ovary into the so-called calyx-tube, which is often petaloid, as in Fuchsia, and is sharply distinguished from the ovary, from which it separates after flowering.

In Clarkia the inner whorl of stamens is often barren, and in an allied genus, Eucarthis, it is absent. In Circaea the flower has its parts in twos. Both sepals and petals are free; the former have a broad insertion, are valvate in bud, and reflexed in the flower; in Fuchsia they are petaloid. The petals have a narrow attachment, and are generally convolute in bud; they are entire (Fuchsia) or bilobed (Epilobium); in some species of Fuchsia they are small and scale-like, or absent (F. aplanata). The stamens, free, and those of the inner whorl are generally shorter than those of the outer whorl. The flowers of Lopertia (Central America) have only one fertile ovary.

The typical quadrilocular ovary contains numerous ovoids on axial placents; the 1-to-2-celled ovary of Circaea has a single ovule in each loculus. The long-sleender style has a capitata (Fuchsia), 4-rayed (Oenothera, Epilobium) or 4-ribbed (Circaea) stigma. The flowers, which have generally an attractive corolla and honey secreted by a swollen disk at the base of the style or on the lower part of the "calyx-tube," are adapted for pollination by insects, chiefly bees and lepidoptera; sometimes by night-flying insects when the flowers are pale and open towards evening, as in evening primrose. The fruit is generally a capsule splitting into 4 valves and leaving a central column on which the seeds are borne as in Epilobium and Oenothera—

5. from Vine's Student's Text-Book of Botany, by permission of Swan Sonnenschein & Co.

A, Young flower of Epilobium hirsutum. c, petals; f, inferior ovary; k, sepals; s, pedicel.

B, Fruit of Epilobium after dehiscence. w, outer wall; m, columnella formed by the sepal; s, seed with tufts of hairs.

in the former the seeds are scattered by aid of a long tuft of silky hairs on the broader end. In Fuchsia the fruit is a berry, which is sometimes edible, and in Circaea a nut bearing recurved bristles. The seeds are exalbuminous. Several of the genera are well known as garden plants, e.g. Fuchsia, Oenothera, Clarkia and Godetia. Evening primrose (Oenothera biennis), a native of North America, occurs apparently wild as a garden escape in Britain. Jussieua is a tropical genus of water- and marsh-herbs with well-developed aerating tissue.

**ONAS**, a Greek sculptor of the time of the Persian wars, a member of the flourishing school of Aegina. Many of his works are mentioned by Pausanias; they included a Hermes carrying the ram, and a strange image of the Black Demeter made for the people of Phigala; also some elaborate groups in bronze set up at Olympia and Delphi. For Hiero I., king of Syracuse, Onatas executed a votive chariot in bronze dedicated at Olympia. If we compare the descriptions of the works of Onatas given us by Pausanias with the well-known pediments of Aegina at Munich we shall find so close an agreement that we may safely take the pedimental figures as an index of the style of Onatas. They are manly, vigorous, athletic, showing great knowledge of the human form, but somewhat stiff and automaton-like.

**ONGE**, the largest lake in Europe next to Ladoga, having an area of 3764 sq. m. It is situated in the government of Olonets in European Russia, and, discharging its waters by the Svir into Lake Ladoga, belongs to the system of the Neva. The lake basin extends north-west and south-east, the direction characteristic of the lakes of Finland and the line of glacier-scoring observed in that region. Between the northern and southern divisions of the lake there is a considerable difference: while the latter has a comparatively regular outline, and contains hardly any islands, the former splits up into a number of inlets, the largest being Povenets Bay, and is crowded with islands (e.g. Klimetsk) and submerged rocks. It is thus the northern division which brings the coast-line up to 870 m. and causes the navigation of the lake to be so dangerous. The north-western shore between Petrozavodsk and the mouth of the river Lumbosa consists of dark clay and gravelly sand. The bottom is covered with stones, broken by protruding, parallel ridges of diorite, which extend far into the lake. The eastern shore, as far as the mouth of the Andoma, is for the most part alluvial, with outcroppings of red granite and in one place (the mouth of the Pyla) diorite and dolomites.

To the south-east are sedimentary Devonian rocks, and the general level of the coast is broken by Mount Ardoma and Cape Petro-pavlovsky (160 ft. above the lake); to the south-west a quartz sandstone (used as a building and monument stone in St Petersburg) forms a fairly bold rim. Lake Onega lies 125 ft. above the sea. The greatest depths, 318 to 408 ft., occur at the entrance to the double bay of Lizhensk and Unisks. On the continuation of this line the depth exceeds 240 ft. in several places. In the middle of the lake the depth is 120 to 282 ft., and less than 120 ft. in the south. The lake is 143 m. long, with an average breadth of 50 m. The most important auxiliates, the Vodka, the Andoma and the Vytega, come from the east. The Kuma, a northern tributary, is so automaton-represented as if it connected the lake with Lake Seg, but at the present time the latter drains to the White Sea. The Onega canal (45 m. long) was constructed in 1818-1851 along the southern shore in order to connect the Svir (and hence Lake Ladoga and the Baltic) with the Vytega, which connects with the Volga. Lake Onega remains free from ice for 209 days in the year (middle of May to second week of December). The water is at its lowest level in the beginning of March; by June it has risen 2 ft. A considerable population is scattered along the shores of the lake, mainly occupied in the timber trade, fisheries and mining industries. Salmon, paliya (a kind of trout), burbot, pike, perchpke and perch are among the fish caught in the lake. Steamboats were introduced in 1832.

The river Onega, which, after a course of 250 m., reaches the Gulf of Onega, an inlet of the White Sea, has no connexion with Lake Onega. At the mouth of this river (on the right bank) stands the town and port of Onega (pop. 2604 in 1897), which dates from settlements made by the people of Novgorod in the 15th century, and known in history as Ustenskaya or Ust-yanaskaya. It has a cathedral, erected in 1796. (P. A. K.; J. T. B.)
ONEIDA—ONEIDA COMMUNITY

ONEIDA, a city of Madison county, New York, U.S.A., on Oneida Creek, about 6 m. S.E. of Oneida Lake, about 15 m. W. of Utica, and about 26 m. E.N.E. of Syracuse. Pop. (1800) 6083; (1800) 6504, of whom 784 were foreign-born; (1910, U.S. Census) 8195. It is served by the New York Central & Hudson River, the New York, Ontario & Western, the West Shore and the Oneida (electric) railways (the last connecting with Utica and Syracuse), and by the Erie Canal. The city lies about 450 ft. above the sea on a level site. Across Oneida Creek, to the south-east, in Oneida county, is the village of Oneida Castle (pop. in 1910, 393), situated in the township of Vernon (pop. in 1910, 3107), and the former gathering place of the Oneida Indians, some of whom still live in the township of Vernon and in the city of Oneida. In the south-eastern part of the city is the headquarters of the Oneida Community (q.v.), which controls important industries here, at Niagara Falls, and elsewhere. Immediately west of Oneida is the village of Wampsville (incorporated in 1906), the county-seat of Madison county. Among the manufactures of Oneida are wagons, cigars, furniture, caskets, silver-plated ware, engines and machinery, steel and wooden pulleys and chucks, steel grage saws, buckets, metal bottle caps, _oneida_ Community manufactured traps and animal traps. The site of Oneida was purchased in 1829-1830 by Sands Higinbotham, in honour of whom one of the municipal parks (the other is Allen Park) is named. Oneida was incorporated as a village in 1848 and chartered as a city in 1901.

ONEIDA (a corruption of their proper name Oneyolka-ono, "people of the stone," in allusion to the Oneida stone, a granite boulder near their former village, which was held sacred by them), a tribe of North American Indians of Iroquois stock, forming one of the Six Nations. They lived around Oneida Lake in New York state, in the region southward to the Susquehanna. They were not loyal to the League's policy of friendliness to the English, but inclined towards the French, and were practically the only Iroquois who fought for the Americans in the War of Independence. As a consequence they were attacked by others of the Iroquois under Joseph Brant and took refuge within the American settlements till the war ended, when the majority returned to their former home, while some migrated to the Thames river district, Ontario. Early in the 19th century they sold their lands, and most of them settled on a reservation at Green Bay, Wisconsin, some few remaining in New York state. The tribe now numbers more than 3000, of whom about two-thirds are in Wisconsin, a few hundreds in New York state, and about 800 in Ontario. They are civilized and prosperous.

ONEIDA COMMUNITY (or Bible Community), an American communistic society at Oneida, Madison county, New York, which has attracted wide interest on account of its pecuniary success, and its peculiar religious and social principles (see COMMUNISM).

Its founder, John Humphrey Noyes (1811-1886), was born in Brattleboro, Vermont, on the 3rd of September 1811. He was of good parentage; his father, John Noyes (1763-1841), was a graduate of and for a time a tutor in Dartmouth College, and was a representative in Congress in 1815-1817; and his mother, Polly Hayes, was an intimate of Rutherford B. Hayes, the present president of the United States. The son graduated at Dartmouth in 1831 and studied law for a year, but having been converted in a protracted revival in 1831 he turned to the ministry, studied theology for one year at Andover (where he was a member of "The Brethren," a secret society of students preparing for foreign missionary work), and then a year and a half at Yale, and in 1833 was licensed to preach by the New Haven Association; but his open preaching of his new religious doctrines, and especially that of present salvation from sin, resulted in the revocation of his license in 1834, and his thereafter being called a Perfectionist. He continued to promulgate his ideas of a higher Christian life, and soon had disciples in many places, one of whom, Harriet A. Holton, a woman of means, he married in 1838. In 1836 he returned to his father's home in Putney, Vt., and founded a Bible School; in 1843 he entered into a "contract of Partnership" with his Putney followers; and in March 1845 the Putney Corporation or Association of Perfectionists was formed.

Although the Putney Corporation or Association was never a community in the sense of common-property ownership, yet it was practically a communal organization, and embodied the radical religious and social principles that subsequently gave such fame to the Oneida Community, of which it may justly be regarded as the beginning and precursor. These principles naturally excited the opposition of the churches in the small Vermont village where the Perfectionists resided, and indignation meetings against them were held; and although they resulted in no personal violence Mr Noyes and his followers considered it prudent to remove to a place where they were sure of more liberal treatment. They accordingly withdrew from Putney in 1847, and accepting the invitation of Jonathan Burt and others, settled near Oneida, Madison county, New York.

Here the community at first devoted itself to agriculture and fruit raising, but had little financial success until it began the manufacture of a steel trap, invented by one of its members, Seward Newhouse, the manufacture of steel chains for use with the traps followed; the canning of vegetables and fruits was begun about 1854, and the manufacture of sewing and embroidery silk in 1866. Having started with a very small capital (the inventoried valuation of its property in 1857 was only $67,000), the community gradually grew in numbers and prospered as a business concern. Its relations with the surrounding population, after the first few years, became very friendly. The members won the reputation of being good, industrious citizens, whose word was always "as good as their bond"; against whom no charge of intemperance, profanity or crime was ever brought. But the communists claimed that among true Christians "mine and thine" in property matters should cease to exist, as among the early pentecostal believers; and, moreover, that the same unselfish spirit should pervade and control all human relations. And notwithstanding these very radical principles, which were freely propounded and discussed in their weekly paper, the communists were not seriously disturbed for a quarter of a century. But Richard Noyes (1837-1879) active measures favouring legislative action against the community, specially instigated by Prof. John W. Mears (1825-1881), were taken by several ecclesiastical bodies of Central New York. These measures culminated in a conference held at Syracuse University on the 14th of February 1879, when denunciatory resolutions against the community were passed and legal measures advised.

Mr Noyes, the founder and leader of the community, had repeatedly said to his followers that the time might come when it would be necessary, in deference to public opinion, to recede from the practical assertion of their social principles; and on the 20th of August of this year (1879) he said definitely to them that in his judgment that time had come, and he thereupon proposed that the community "give up the practice of Complex Marriage, not as renouncing belief in the principles and prospective finality of that institution, but in deference to public sentiment. This proposition was considered and accepted in full assembly of the community on the 26th of the same month. Great change was followed by other changes of vital importance, finally resulting in the transformation of the Oneida Community into the incorporated Oneida Community, Limited, a co-operative joint-stock company, in which each person's interest was represented by shares of stock standing in his name on the books of the company.

In the reorganization the adult members fared alike in the matter of remuneration for past services—those who by reason of ill-health had been unable to contribute to the common fund receiving the same as those who by reason of strength and ability had contributed most thereto; besides, the old and infirm had the option of accepting a life-guarantee in lieu of work; and hence there were no cases of suffering and want at the time the transformation from a common-property interest to an individual stock interest was made; and in the new company all were guaranteed remunerative labour.
O’NEILL (FAMILY)

This occurred on the 1st of January 1881, at which time the business and property of the community were transferred to the incorporated stock company, and stock issued therefor to the amount of $600,000. In the subsequent twenty-eight years this capital stock was doubled, and dividends averaging more than 6% per annum were paid. Aside from the home buildings and the large acreage devoted to agriculture and fruit raising, the present capital of the company is invested, first, in its hardware department at Kenwood, N.Y., manufacturing steel game-traps, and weedless chains of every description; second, the silk department at Kenwood, N.Y., manufacturing sewing silk, machine twist and embroidery silks; third, the fruit department at Kenwood, N.Y., whose reputation for putting up pure, wholesome fruits and vegetables is probably the highest in the country; fourth, the tableware department, at Niagara Falls, N.Y., which manufactures the now celebrated Community Silver; fifth, the Canadian department, with factory at Niagara Falls, Ontario, Canada, where the hardware lines are manufactured for Canadian trade. The annual sales of all departments aggregate over $2,000,000. The officers of the company consist of a president, secretary, treasurer and assistant treasurer, and there were in 1909 eleven directors. Each of the five leading departments is managed by a superintendent, who is also the general manager. Nearly all the superintendents and the general manager were in 1909 young men who were born in the community, and have devoted their life-work to the interests of the company. Selling offices are maintained in New York City, Chicago, St Louis, Cleveland, O., Richmond, Va., Atlanta, Ga., and San Francisco.

In addition to the members of the society the company employs between 1500 and 2000 workmen. The policy has been to avoid trade-unions, but to pay higher wages and give better conditions than other employers in similar lines, and by so doing to obtain a better selection of workmen. The conditions of work as well as of living have been studied and developed with the idea of making both healthful and attractive. With this in view the company has laid out small villages, in many ways making them attractive and sanitary, and has encouraged the building of houses by its employés. Much has been accomplished in this direction by providing desirable building-sites at moderate expense, and paying a bonus of from $100 to $500 in cash to every one who builds his own home. The company has also taken an interest in the schools in the vicinity of its factories, with the idea of offering to the children of its employees facilities for a good education.

The communism of John H. Noyes was based on his interpretation of the New Testament. In his pamphlet, Bible Communism (1848), he affirmed that the second coming of Christ occurred at the close of the apostolic age, immediately after the destruction of Jerusalem, and he argued from many New Testament passages, especially 1 John 1, 7, that after the second coming and the beginning of Christ’s reign upon the earth, the true standard of Christian character was sinlessness, which was possible through vital union with Christ, that all selfishness was to be done away with, both in property in things and in persons, or, in other words, that communism was to be finally established in all the relations of life. But, while affirming that the same spirit which on the day of Pentecost abounded exclusiveness in regard to money tends to obliterate all other property distinctions, he had no affiliation with those commonly termed “Luddites,” because their principles and practices seemed to him to tend toward anarchy. “Our Communities,” he said, “are families as distinctly bounded and separated from promiscuous society as ordinary households. The tie that binds us together is as permanent and sacred, to say the least, as that of common marriage, for it is our religion. We receive no new members (except by deception and mistake) who do not give heart and hand to the family interest for life and for ever. Community of property extends just as far as freedom of love. Every man’s care and every dollar of the common property are pledged for the maintenance and protection of the women and the education of the children of the Community.”

The community was much interested in the question of race improvement by scientific means, and maintained with much force of argument that at least as much scientific attention should be given to the physical improvement of human beings as is given to the improvement of domestic animals; and they referred to the results of their own incomplete stiri-cultural experiments as indicative of what may be expected in the far future, when the conditions of human reproduction are no longer controlled by chance, social position, wealth, impulse or lust.

The community claimed to have solved among themselves the labour question, all kinds of service being regarded as equally honourable, and every person being respected according to his real character.

The members had some peculiarities of dress, mostly confined, however, to the women, whose costumes included a short dress and pantaloons, which were appreciated for their convenience, if not for their beauty. The women also adopted the practice of wearing short hair, which it was claimed saved time and vanity. Tobacco, intoxicants, profanity, obscenity found no place in the community. The community diet consisted largely of vegetables and fruits; meat, tea and coffee being served only occasionally.

For securing good order and the improvement of the members, the community placed much reliance upon a very peculiar system of plain speaking they termed mutual criticism, which originated in a secret society of missionary brethren with which Mr Noyes was connected while pursuing his theological studies at Andover Seminary, and whose members submitted themselves in turn to the sincerest comment of one another as a means of personal improvement. Under Mr Noyes’s supervision it became in the Oneida Community a principal means of discipline and government. There was a standing committee of criticism, selected by the community, and changed from time to time, thus giving all an opportunity to serve both as critics and subjects, and justifying the term “mutual” which they gave to the system. The subject was free to have others besides the committee present, or to have critics only of his own choice, or to invite an expression from the whole community.

Noyes edited The Perfectionist (New Haven, Connecticut, 1834, and Putney, Vermont, 1843-1848); The Witness (Ithaca, New York, and Putney, 1838-1843); The Spiritual Magazine (Putney, 1846-1847; Oneida, 1852-1850); The Free Church Circular (Oneida, 1850-1851); and virtually, though not always nominally, The Circular and The Oneida Circular (Brooklyn, 1851-1853; Oneida, N.Y., and St. Albans, 1854-1876); and The American Socialist (Oneida, 1876-1880). He was the author of The Way of Holiness (Putney, 1838); The Berean (Putney, 1847), containing an exposition of his doctrines of Salvation from Sin; the Second Coming of Christ; the War in Heaven; the Redemption of Man; God’s Will; The Problem of Good Birth; the Millennium: Our Relations to the Primitive Church, &c. &c.; History of American Socialism (Philadelphia, 1870); Home Talks (Oneida, 1876); and numerous pamphlets. See a series of articles in the Manufacturer and Builder (New York, 1891-1894), by “C. R. Edson” (i.e. C. E. Robinson); The Oneida Circular, by Allan Estlake (a member of the community) (1900); Morris Hillquit’s History of Socialism in the United States (New York, 1903), and especially William A. Hinds’s American Communities and Co-operative Colonies (3rd ed., Chicago, 1908).

O’NEILL, the name of an Irish family tracing descent from Niall, king of Ireland early in the 5th century, and known in Irish history and legend as Niall of the Nine Hostages. He is said to have made war not only against lesser rulers in Ireland, but also in Britain and Gaul, stories of his exploits being related in the Life of Leinster and the Book of Ballymote, both of which, however, are nearly or entirely late medieval compilations. This king had fourteen sons, one of whom was Eoghan (O’Wen), from whom the O’Neills of the later history were descended. The descendants of Niall spread over Ireland and became divided into two main branches, the northern and the southern Hy Neill, to one or other of which nearly all the high-kings (ard-rí) of Ireland from the 5th to the 12th century belonged; the descendants of Eoghan being the chief of the northern Hy Neill.1 Eoghan was grandfather of Murkertagh (Muircheartach) (d. 533).

1 A list of these kings will be found in P. W. Joyce’s A Social History of Ancient Ireland (London, 1903), vol. i. pp. 70, 71.
said to have been the first Christian king of Ireland, whose mother, Eric or Erca, became by a subsequent marriage the grandmother of St Columba. Of this monarch, known as Murkertagh MacNeill (Niall) by some, by others, and in the annals as Murkertagh Mac Erc, the story is told, illustrating an ancient Celtic custom, that in making a league with a tribe in Meath he emphasized the inviolability of the treaty by having it written with the blood of both clans mixed in one vessel. Murkertagh was chief of the great north Irish clan, the Cinel Eoghan, and after becoming king of Ireland about the year 517, he wrested from a neighbouring clan a tract of country in the modern County Derry, which remained till the 17th century in the possession of the Cinel Eoghan. The inauguration stone of the Irish kings, the Lia Fail, or Stone of Destiny, fabled to have been the pillow of the patriarch Jacob on the occasion of his dream of the heavenly ladder, was said to have been presented by Murkertagh to the king of Dalriada, by whom it was conveyed to Dunstaffnage Castle in Scotland (see Scone). A lineal descendant of Murkertagh was Niall Frassach (i.e. of the showers), who became king of Ireland in 763; his surname, of which several fanciful explanations have been suggested, probably commemorating merely weather of exceptional severity at his birth. His grand-son, Niall (791-845), drove back the Vikings who in his time began to infest the shores. Niall's son, Aedh (Hugh) Finnilaith, was father of Niall Glundubh (i.e. Niall of the black knee), one of the most famous of the early Irish kings, from whom the family surname of the O'Neills was derived. His brother Domhnall (Donnell) was king of Aliech, a district in Donegal and Derry; the royal palace, the ruined masonry of which is still to be seen, being on the summit of a hill 800 ft. high overlooking loughs Foyle and Swilly. On the death of Domhnall in 911 Niall Glundubh became king of Aliech, and he then attacked and defeated the king of Dalriada at Glarryford, in County Antrim, and the king of Ulidia near Ballymena. Having thus extended his dominion he became king of Ireland in 915. To him is attributed the revival of the ancient meeting of Irish clans known as the Fair of Telltown (see Ireland: Early History). He fought many battles against the Norsemen, in one of which he was killed in 919 at Kilmashoge, where his place of burial is still to be seen.

His son Murkertagh, who gained a great victory over the Norse in 926, is celebrated for his triumphant march round Ireland, the Moirtimchell Eiream, in which, starting from Portglenone, the capital of the Barrow, he continued a circuit of the island at the head of his armed clan, returning with many captive kings and chieftains. From the dress of his followers in this expedition he was called "Murkertagh of the Leather Cloaks." The exploit was celebrated by Cormacan, the king's bard, in a poem that has been printed by the Irish Archaeological Society; and a number of Murkertagh's other deeds are related in the Book of Leinster. He was killed in battle against the Norse in 943, and was succeeded as king of Aliech by his son, Donnell Ua Niall (i.e. O'Neill, grandson of Neill, or Niall, the name O'Neill becoming about this time an hereditary family surname), whose grandson, Fiaidhert, became renowned for piety by going on a pilgrimage to Rome in 1030.

Aedh (Hugh) O'Neill, chief of the Cinel Eoghan, or lord of Tir-Eoghain (Tir-Owen, Tyrone) at the end of the 12th century, was the first of the family to be brought prominently into conflict with the Anglo-Norman monarchy, whose pretensions he took the lead in disputing in Ulster. It was probably his son or nephew (for the relationship is uncertain, the genealogies of the families of O'Neill and Donnell having diverged in the Derry district) by the discovery of the existence of the same name in different branches of the family) Hugh O'Neill, lord of Tyrone, who was styled "Head of the liberality and valour of the Irish." Hugh's son, Brian, by gaining the support of the earl of Ulster, was inaugurated3 prince, or lord, of Tyrone in 1291; and his son Henry became lord of the Clann Aodha Budhhe (Clanaboy or Clandeboye), early in the 14th century; his grandson Murkertagh he sought to the front, and his great-grandson Hugh, described as "the most renowned, hospitable and valorous of the princes of Ireland in his time," greatly consolidated the power of the O'Neills. Niall Og O'Neill, one of the four kings of Ireland, accepted knighthood from Richard II of England; and his son Eoghan formally acknowledged the supremacy of the English crown, though he afterwards ravaged the Pale, and was inaugurated "the O'Neill" (i.e. chief of the clan) on the death of his kinsman Domhnall Boy O'Neill; a dignity from which he was deposed in 1455 by his son Henry, who in 1463 was acknowledged as chief of the Irish kings by Henry VII. of England. Contemporary with him was Neill Mor O'Neill (see below), lord of Clanaboy, from whose son Brian was descended the branch of the O'Neills who, settling in Portugal in the 18th century, became prominent among the Portuguese nobility, and who at the present day are the representatives in the male line of the ancient Irish kings of the house of O'Neill.

O'NEILL (FAMILY)

1 The Cinel, or Kinel, was a group of related clans occupying an extensive district. See Joyce, op. cit. i. 166.
2 The adoption of hereditary names became general in Ireland, in obedience, it is said, to an ordinance of Brian Bore, about the end of the 10th century. For the method of their formation see Joyce, op. cit. ii. 19.
3 The ceremony of "inauguration" among the ancient Irish clans was a elaborate and important one. A stone inauguration chair of the O'Neills is preserved in the Belfast Museum. See Joyce, op. cit. i. 46.
baron of Dungannon, if Shane would submit to her authority and that of her deputy. O'Neill, however, refused to put himself in the hands of Sussex without a guarantee for his safety, and his claims in other respects were so exacting that Elizabeth consented to measures being taken to subdue him and to restore Brian. An attempt to foment the enmity of the O'Donnells against him was frustrated by Shane's capture of Calvagh O'Donnell, whom he kept a close prisoner for nearly three years. Elizabeth, whose prudence and parsimony were averse to so formidable an undertaking as the complete subjugation of the powerful Irish chieftain, desired peace with him at almost any price; especially when the devastation of his territory by Sussex brought him no nearer to submission. Sussex, indignant at Shane's request for his sister's hand in marriage, and his demand for the withdrawal of the English garrison from Armagh, was not supported by the queen, who sent the earl of Kildare to arrange terms with O'Neill. The latter, making some trifling concessions, consented to present himself before Elizabeth. Accompanied by Ormonde and Kildare he reached London on the 4th of January 1562. Camden describes the wonder with which O'Neill's wild gallowglasses were seen in the English capital, with their heads bare, their long hair falling over their shoulders and clipped short in front above the eyes, and clothed in rough yellow shirts. Elizabeth was less concerned with the respective claims of Brian and Shane, the one resting on an English patent and the other on the Celtic custom, than with the question of policy involved in supporting or rejecting the demands of her proud suppliant. Characteristically, she temporized; but finding that O'Neill was in danger of becoming a tool in the hands of Spanish intriguers, she permitted him to return to Ireland, recognizing him as "the O'Neill," and chieftain of Tyrone; though a reservation was made of the rights of Hugh O'Neill, who had meantime succeeded his brother Brian as baron of Dungannon, Brian having been murdered in April 1562 by his kinsman Turlough Luineach O'Neill.

There were at this time three powerful contemporary members of the O'Neill family in Ireland—Shane, Turlough and Hugh, 2nd earl of Tyrone. Turlough had been elected tanist (see Tanistry) when his cousin Shane was inaugurated as king of Ulster, and he schemed to supplant him in the higher dignity during Shane's absence in London. The feud did not long survive Shane's return to Ireland, where he quickly re-established his authority, and in spite of Sussex renewed his turbulent tribal warfare against the O'Donnells and others. Elizabeth at last authorized Sussex to take the field against Shane, but two or three expeditions failed to accomplish anything except some depredation in O'Neill's country. Sussex had tried in 1561 to procure Shane's assassination, and Shane now laid the whole blame for his lawless conduct on the lord deputy's repeated alleged attempts on his life. Force having ignominiously failed, Elizabeth consented to treat, and hostilities were stopped on terms that gave O'Neill practically the whole of his demands. O'Neill now turned his hand against the MacDonnells, claiming that he was serving the queen of England in harrying the Scots. He fought an indecisive battle with Sorley Boy MacDonnell near Coleraine in 1564, and the following year marched through Antrim towards Derry, which was taken with the aid of the MacDonnell, and took Sorley Boy prisoner. This victory greatly strengthened Shane O'Neill's position, and Sir Henry Sidney, who became lord deputy in 1566, declared to the earl of Leicester that Lucifer himself was not more puffed up with pride and ambition than O'Neill. Preparations were made in earnest for his subjugation. O'Neill ravaged the Pale, failed in an attempt on Dundalk, made a truce with the MacDonnells, and sought help from the earl of Desmond. The English, on the other hand, invaded Donegal and restored O'Donnell. Failing in an attempt to arrange terms, and also in obtaining the help which he solicited from France, O'Neill was utterly routed by the O'Donnells at Lettermenny; and seeking safety in flight, he threw himself on the mercy of his enemies, the MacDonnells. Attended by a small body of gallowglasses, and taking his prisoner Sorley Boy with him, he presented himself among the MacDonnells near Cushendun, on the Antrim coast. Here, on the 2nd of June 1567, whether by premeditated treachery or in a sudden brawl is uncertain, he was slain by the MacDonnells, and was buried at Gienarm. In his private character Shane O'Neill was a brutal, uneducated savage. He divorced his first wife, a daughter of James MacDonnell, and treated his second, a sister of Calvagh O'Donnell, with gross cruelty in revenge for her brother's hostility; Calvagh himself, when Shane's prisoner, he subjected to continual torture; and Calvagh's wife, whom he made his mistress, and by whom he had several children, endured ill-use at the hands of her drunken captor, who is said to have married her in 1569.

Turlough Luineach O'Neill (c. 1530-1595), 1st earl of Clanconnell, was inaugurated chief of Tyrone on Shane's death. Making professions of loyalty to the queen of England, he sought to strengthen his position by alliance with the O'Donnells, MacDonnells and MacQuillans. But his conduct giving rise to suspicions, an expedition under the earl of Essex was sent against him, which met with such doubtful success that in 1575 a treaty was arranged by which O'Neill received extensive grants of land and permission to extend his boundaries in Ulster. In 1578 he was created baron of Clougher and 1st earl of Clanconnell for life; but on the outbreak of rebellion in Munster his attitude again became menacing, and for the next few years he continued to intrigue against the English authorities. The latter, as a counterpoise to Turlough, supported his cousin Hugh, brother of Brian, whom Turlough had murdered. After several years of rivalry and much fighting between the two relatives, Turlough resigned the headship of the clan in favour of Hugh, who was inaugurated O'Neill in 1593. Turlough died in 1595.

Hugh O'Neill (c. 1540-1616), 2nd earl (known as the great earl) of Tyrone, was the second son of Matthew, reputed illegitimate son of Conn, 1st earl of Tyrone. He succeeded his brother, Brian, when the latter was murdered by Turlough in 1562, as baron of Dungannon. He was brought up in London, but returned to Ireland in 1587 after the death of Shane, under the direction of Sir Henry Sidney. He served with the English against Desmond in Munster in 1589, and assisted Sir John Perrot against the Scots of Ulster in 1584. In the following year he was allowed to attend parliament as earl of Tyrone, though Conn's title had been for life only, and had not been assumed by Brian. Hugh's constant disputes with Turlough were fomented by the English with a view to weakening the power of the O'Neill, but after Hugh's inauguration as the O'Neill on Turlough's resignation in 1593, he was left without a rival in the north. His career was marked by unreasing duplicity, at one time giving evidence of submission to the English authorities, at another intriguing against them in conjunction with lesser Irish chieftains. Having roused the ire of Sir Henry Bagnal (or Bagenal) by eloping with his sister in 1591, he afterwards assisted him in defeating Hugh Maguire at Béleek in 1593; and then again went into opposition and sought aid from Spain and Scotland. Sir John Norris was accordingly ordered to Ireland with a considerable force to subdue him in 1595, but Tyrone succeeded in eluding him. He was assisted by the earl of Essex, and Sligo began to be threatened. But Norris was prepared; and he was therefore engaged at Drogheda in 1596, and was there surprised and captured by Sir Henry Sidney. What became of O'Neill is uncertain, but it is certain that he was either executed or sold to the Spaniards.
from time to time as circumstances required, professions of loyalty which deceived Sir John Norris and the earl of Ormonde. In 1598 a cessation of hostilities was arranged, and a formal pardon granted to Tyrone by Elizabeth. Within two months he was again in the field, and on the 14th of August he destroyed an English force under Baginal at the Yellow Ford on the Blackwater. If the earl had known how to profit by this victory, he might now have successfully withstood the English power in Ireland; for in every part of Ireland—and especially in the south, where James Fitzthomas Fitzgerald with O'Neill's support was asserting his claim to the earldom of Desmond at the head of a formidable army of Geraldine clansmen—discontent broke into flame. But Tyrone, who possessed but little generalship, procrastinated until the golden opportunity was lost. Eight months after the battle of the Yellow Ford, the earl of Essex landed in Ireland to find that Tyrone had done nothing in the interval to improve his position. Acting on the queen's explicit instructions, Essex, after some ill-managed operations, had a meeting with Tyrone at a ford on the Lagan on th 7th of September 1599, where a truce was arranged; but Elizabeth was displeased by the favourable conditions allowed to the O'Neill and by Essex's treatment of him as an equal. Tyrone continued to insist on a preferment to the bishops, and professed a manifesto to the Catholics of Ireland summoning them to join his standard; protesting that the interests of religion were his first care. After an inconclusive campaign in Munster in January 1600, he returned in haste to Donegal, where he received supplies from Spain and a token of encouragement from Pope Clement VIII. In May of the same year Sir Henry Docwra, at the head of a considerable army, took up a position at Derry, while Mountjoy marched from Westmeath to Newry to support him, compelling O'Neill to retire to Armagh, a large reward having been offered for his capture alive or dead.

The appearance of a Spanish force at Kinsale drew Mountjoy to Munster in 1601; Tyrone followed him, and at Bandon joined forces with O'Donnell and with the Spaniards under Don John D'Aquila. The attack of these allies on the English completely failed. O'Donnell went to Spain, where he died soon afterwards, and Tyrone with a shattered force made his way once more to the north, where he renewed his policy of ostensibly seeking pardon while warily evading his enemies. Early in 1603 Elizabeth instructed her son, James, to open negotiations with the rebellious chieftains; and in April, Tyrone's ignorance of Elizabeth's death, made his submission to Mountjoy. In Dublin, whither he proceeded with Mountjoy, he heard of the accession of King James, at whose court he presented himself in June accompanied by Rory O'Donnell, who had become chief of the O'Donnells after the departure of his brother Hugh Roe. The English courtiers were greatly incensed at the gracious reception accorded to these notable rebels by King James; but although Tyrone was confirmed in his title and estates, he had no sooner returned to Ireland than he again engaged in dispute with the government concerning his rights over certain of his feudatories, of whom Donal O'Cahan was the most important. This dispute dragged on till 1607, when Tyrone arranged to go to London to submit the matter to the king. Warned, however, that his arrest was imminent, and possibly persuaded by Rory O'Donnell (created earl of Tyrconnell in 1603), whose relations with Spain had endangered his own safety, Tyrone resolved to fly from the country.

"The flight of the ears," one of the most celebrated episodes in Irish history, occurred on the 14th of September 1606, when Tyrone and Tyrconnell embarked at midnight at Rathmullen on Lough Swilly, with their wives, families and retainers, numbering ninety-nine persons, and sailed for Spain. Driven by contrary winds to take shelter in the Seine, the refugees passed the winter in the Netherlands, and in April 1608 proceeded to Rome, where they were welcomed and hospitably entertained by Pope Paul V., and where Tyrconnell died the same year. In 1613 Tyrone was outlawed and attainted by the Irish parliament, and he died in Rome on the 20th of July 1616. He was four times married, and had a large number both of legitimate and illegitimate children.

**O’NEILL (FAMILY)**

**Sir Phelim O’Neill** (c. 1603–1653), a kinsman and younger contemporary of the earl of Tyrone, took a prominent part in the rebellion of 1641. In that year he was elected member of the Irish parliament for Dungannon, and joined the earl of Antrim and other lords in concerting measures for supporting Charles I. in his struggle with the parliament. On the 22nd of October 1641 he surprised and captured Charlemont Castle; and having been chosen commander-in-chief of the Irish forces in the north, he forged and issued a pretended commission from Charles I. sanctioning his proceedings. Phelim and his followers committed much depredation in Ulster on the pretext of reducing the Scots; and he attempted without success to take Drogheda, being compelled by Ormonde to raise the siege in April 1642. He was responsible for many of the barbarities committed by the Catholics during the rebellion.\(^1\) During the summer his fortune ebbed, and he was soon superseded by his kinsman Owen Roe O’Neill, who returned from military service abroad at the end of July.

**Owen Roe O’Neill** (c. 1590–1649), one of the most celebrated of the O’Neills, the subject of the well-known ballad “The Lament for Owen Roe,” was the son of Art O’Neill, a younger brother of Hugh, 2nd earl of Tyrone. Having served with the most responsible leaders in the Spanish army, he was immediately recognized on his return as the natural representative of the O’Neills. Phelim resigned the northern command in his favour, and escorted him from Lough Swilly to Charlemont. But jealousy between the kinsmen was complicated by differences between Owen Roe and the Catholic council which met at Kilkenny in October 1642. Owen Roe professed to be acting in the interest of Charles I.; but his real aim was the complete independence of Ireland, while the Anglo-Norman Catholics represented by the council desired to secure religious liberty and an Irish constitution under the crown of England.

Although Owen Roe O’Neill possessed the qualities of a general, the struggle dragged on inconclusively for three or four years. In March 1646 a cessation of hostilities was arranged between Ormonde and the Catholics; and O’Neill, furnished with supplies by the papal nuncio, Rinuccini, turned against the Scottish parliamentary army under General Monro, who had been operating with fluctuating success in Ireland since April 1642. On the 5th of June 1646 O’Neill utterly routed Monro at Benburb, on the Blackwater; but, being summoned to the south by Rinuccini, he failed to accomplish his mission, and was forced to remain unmolested at Carrickfergus. For the next two years confusion reigned supreme among the numerous factions in Ireland, O’Neill supporting the party led by Rinuccini, though continuing to profess loyalty to Ormonde as the king of England’s representative. Isolated by the departure of the papal nuncio from Ireland in February 1649, he made overtures for alliance to Ormonde, and afterwards with success to Monck, who had superseded Monro in command of the parliamentarians in the north. O’Neill’s chief need was supplies for his forces, and failing to obtain them from Monck he turned once more to Ormonde and the Catholic confederates, with whom he prepared to co-operate more earnestly when Cromwell’s arrival in Ireland in August 1649 brought the Catholic party face to face with serious danger. Before, however, anything was accomplished by this combination, Owen Roe died on the 6th of November 1649.

The alliance between Owen Roe and Ormonde had been opposed by Phelim O’Neill, who after his kinsman’s death expected to be restored to his former position of command. In this he was disappointed; but he continued to fight against the parliamentarians till August 1652, when a reward was offered for his apprehension. Betrayed by a kinsman while hiding in Tyrone, he was tried for high treason in Dublin, and executed on the 10th of March 1653. Phelim married a daughter of the marquis of Huntly, by whom he had a son Gordon O’Neill, who was member of parliament for Tyrone in 1689; fought for the king at the siege of Derry and at the battles of Aughrim and the

Boye; and afterwards commanded an Irish regiment in the
French service, and died in 1704.

Daniel O'Neill (c. 1612–1684), son of Conn MacNeill
MacNeill, was a member of the Clanaboy branch of the
family, whose wife was a sister of Owen Roe, was prominent
in the Civil Wars. He spent much of his early life at the
court of Charles I., and became a Protestant. He commanded a
troop of horse in Scotland in 1639; was involved in army plots in
1641, for which he was committed to the Tower, but escaped abroad;
and on the outbreak of the Civil War returned to England and
served with Prince Rupert, being present at Marston Moor, the
second battle of Newbury and Naseby. He then went to
Ireland to negotiate between Ormonde and his uncle, Owen
Roe O'Neill. He was made a major-general in 1649, and but for
his Protestantism would have succeeded Owen Roe as chief of
the O'Neills. He joined Charles II. at the Hague, and took part
in the expedition to Scotland and the Scotch invasion of England
in 1652. At the Restoration he received many marks of favour
from the king, including grants of land and lucrative monopolies.
He died in 1654.

Hugh O'Neill (d. c. 1660), son of Owen Roe's brother Art
Oge, and therefore known as Hugh Mac Art, had served with
some distinction in Spain before he accompanied his uncle,
Owen Roe, to Ireland in 1642. In 1646 he was made a major-
general of the forces commanded by Owen Roe; and after the
death of the latter he successfully defended Clonmel in 1650
against Cromwell, on whom he inflicted the latter's most severe
defeat in Ireland. In the following year he so stubbornly
resisted Ireton's attack on Limerick that he was excepted from
the benefit of the capitulation, and, after being condemned to
death and reprieved, was sent as a prisoner to the Tower of
London. Released in 1652 on the representation of the Spanish
ambassador that O'Neill was a Spanish subject, he repaired to
Spain, whence he wrote to Charles II. in 1660 claiming the
earldom of Tyrone. He probably died in Spain, but the date of
his death is unknown.

The Clanaboy (or Clandeboy) branch of the O'Neills descended
from the ancient kings through Neill Mor O'Neill, lord of
Clanaboy in the time of Henry VIII., ancestor (as mentioned
above) of the Portuguese O'Neills. Neill Mor's great-great-
grandson, Henry O'Neill, was created baronet of Killeleagh in
1666. His son, Sir Neill O'Neill fought for James II. in Ireland,
and died of wounds received at the battle of the Boyne. Through
an elder line from Neill Mor was descended Brian Mac Phelim
O'Neill, who was treacherously seized in 1573 by the earl of
Essex, whom he was hospitably entertaining, and executed together
with his wife and brother, some two hundred of his clan being
at the same time massacred by the orders of Essex. (See
Essex, Walter Devereux, 1st earl of.) Sir Brian Mac Phelim's
son, Shane Mac Brian O'Neill, was the last lord of Clanaboy, and
from him the family castle of Edendufffallack, on the shores of
LoUGH Neagh in Co. Antrim, was named Shane's Castle. He
joined the rebellion of his kinsman Hugh, earl of Tyrone, but
submitted in 1586.

In the 18th century the commanding importance of the
O'Neills in Irish history had come to an end. But John O'Neill
(1740–1798), who represented Randalstown in the Irish parlia-
ment 1761–1783, and the county of Antrim from the latter year
till his death, took an active part in debate on the popular side,
being a strong supporter of Catholic emancipation. He was
one of the delegates in 1780 from the Irish parliament to George,
prince of Wales, requesting him to assume the regency as a
matter of right. In 1793 he was raised to the peerage of Ireland
as Baron O'Neill of Shane's Castle, and in 1795 was created a
viscount. In defending the town of Antrim against the rebels in
1798 O'Neill received wounds from which he died on the 18th of
July, being succeeded as Viscount O'Neill by his son Charles
Henry St John (1779–1841), who in 1800 was created Earl
O'Neill. Dying unmarried, when the earldom therefore became
extinct, Charles was succeeded as Viscount O'Neill by his brother
John Bruce Richard (1780–1855), a general in the British army;
on whose death without issue in 1855 the male line in the United
Kingdom became extinct. The estates then devolved on William,
Chichester, great-grandson of Arthur Chichester and his wife Mary, only child of Henry (d. 1724), eldest son of John O'Neill of Shane's Castle.

William Chichester (1813–1858), 1st Baron O'Neill, a
clergyman, on succeeding to the estates as heir-general, assumed
by royal licence the surname and arms of O'Neill; and in 1858
was created Baron O'Neill of Shane's Castle. On his death in
1873 he was succeeded by his son Edward, 2nd Baron O'Neill
(b. 1839), who was member of parliament for Co. Antrim
1863–1880, and who married in 1873 Louisa, daughter of the
11th earl of Dunldonal.

For the history of the ancient Irish kings of the Hy Nell see:
The Book of Leinster, edited with introduction by R. Atkinson
(Royal Irish Academy, 1848), and The Annals of Ulster, edited
by W. M. Hennessy and B. MacCarthy (4 vols., Dublin, 1887–1901);
The Annals of Loch Cé, edited by W. M. Hennessy (Rolls Series,
London, 1871). For the later period see: F. W. Joyce, A Short
History of Ireland (London, 1893), and A Social History of Ancient
Ireland (2 vols., London, 1903); The Annals of Ireland by the Four
Masters, edited by J. O'Donovan (7 vols., Dublin, 1851); Sir J. T.
Gilbert, History of the Viscounts of Ireland (Dublin, 1865), and, espe-
cially Owen Roe O'Neill, Contemporary History of Affairs in Ireland,
1641–1652 (Irish Archaeol. Soc., 3 vols., Dublin, 1879); also History
of the Irish Confederation and the War in Ireland (Dublin, 1882);
John O'Neil, Irish Pedigrees (Dublin, 1881); The Montgomery MSS.,
"History of Clanaboy, or the Life of O'Neill (Dublin, 1903); F. W.
Taylor, An Account of the Earlier History (3 vols., London, 1885–1890); J. F.
Tayor, Owen Roe O'Neill (London, 1896); John Mitchell, Life and
Times of Hugh, Earl of Tyrone, with an Account of his Predecessors,
Con co., and Successors (Dublin, 1897); W. O'Donnell, O'Neill of
Dublin (Dublin, 1893). For the O'Neills of the 18th century, and
especially the 1st Viscount O'Neill, see The Charlemont Papers,
and F. Hanly, Memoirs of J. Caulfeild, Earl of Charlemont (2 vols.,
London, 1886); Records of the O'Neill, Productive History of Ireland
in the 17th and 18th Centuries, by Thomas Mathews (3 vols., Dublin, 1907), an ill-arranged and
uncritical work, but contains a mass of traditional and legendary lore, and a number of translations of ancient poems, and genealogical tables of ducal
life. (R. J. M.)

O'Neill, Eliza (1791–1872), Irish actress, was the daughter
of an actor and stage manager. Her first appearance on the
stage was made at the Crow Street theatre in 1811 as the Widow
Cheery in The Soldier's Daughter, and after several years in
Ireland she came to London and made an immediate success just
at Covent Garden in 1814. For five years she was the favourite of the town in comedy as well as tragedy, but in the latter she particularly excelled, being frequently compared,
not to her disadvantage, with Mrs Siddons. In 1819 she married
William Wrixon Becher, an Irish M.P. who was created a
baronet in 1831. She never returned to the stage, and died on
the 29th of October 1872.

Oneonta, a city in the township of the same name, in
the south-central part of Otsego county, New York, U.S.A.,
the on the N. slope of the Susquehanna river, about 82 m. S.W. of Albany.
Pop. (1870) 300; (1880) 6274; (1900) 7147, of whom 456 were
foreign-born (1870). U.S. const. on 1100 ft. above sea-level. It is served by the Ulster & Delaware, by the Susquehanna division of the Delaware & Hudson, and by the Oneonta & Mohawk Valley (electric) railways. In Oneonta are a state normal school (1889), a state armoury, and the Aurelia Fox Memorial Hospital. The city is situated in a good
agricultural region. The principal manufactures are machine-
shop products (the Delaware & Hudson has repair and machine
shops at Oneonta), knits goods, silk goods, lumber and planing
mill products, &c. The first settlement was made about 1780.
The township was erected in 1830 from parts of Milford and
Otego. Oneonta was known as Milfordville until 1850, when
it received its present name. It was first incorporated as a
village in 1848, and was chartered as a city in 1908, the charter
taking effect on the 1st of January 1909. The name "Oneonta" is derived from Ondule or Onoenta, the
Indian name of a creek flowing through the city.

See Edwin F. Bacon, Otsego County, N.Y. (Oneonta, 1902); and
Dudley M. Campbell, A History of Oneonta (Oneonta, 1906).
ONESICRITUS

ONESICRITUS, or Onesicrates, of Aegina or Astypaleia (probably simply the “old city” of Aegina), one of the writers on Alexander the Great. At an advanced age he became a pupil of Diogenes the Cynic, and gained such repute as a student of philosophy that he was selected by Alexander to hold a conference with the Indian Gymnosophists. When the fleet was constructed on the Hydaspes, Onesicritus was appointed chief pilot (in his vanity he calls himself commander), and in this capacity accompanied Nearchus on the voyage from the mouth of the Indus to the Persian gulf. He wrote a diffuse biography of Alexander, which in addition to historical details contained descriptions of the countries visited, especially India. After the king’s death, Onesicritus appears to have completed his work at the court of Lysimachus, king of Thrace. Its historical value was considered small, it being avowedly a panegyric, and contemporaries (including even Alexander himself) regarded it as untrustworthy. Strabo especially takes Onesicritus to task for his exaggeration and love of the marvellous. His Paráphus (or description of the coasts of India) probably formed part of the work, and, incorporated by Juba II. of Mauretania with the accounts of coasting voyages by Nearchus and other geographers, and circulated by him under the name of Onesicritus, was largely used by Pliny.

ONION (Fr. oignon, Lat. unio, liberally unity, oneness, applied to a large pearl and to a species of onion), Allium cepa (nat. ord. Liliaceae), a hard bulbous biennial, which has been cultivated in Britain from time immemorial, and is one of the earliest of cultivated species; it is represented on Egyptian monuments, and one variety cultivated in Egypt was accorded divine honours. It is commonly cultivated in India, China and Japan. A. de Candolle, arguing from its ancient cultivation and the antiquity of the Sanskrit and Hebrew names, regards it as a native of western Asia.

The onion should be grown in an open situation, and on a light, rich, well-worked soil, which has not been recently manured. In England the principal crop may be sown at any time from the middle of February to the middle of March, if the weather is fine and the ground sufficiently dry. The seed should be sown in shallow drills, ½ in. apart, the ground being made as level and firm as possible, and the plants should be regularly thinned and kept free from weeds. A rail or frame of hurdles they should be tied up to, 2 ft. apart, the latter distance in very rich soil. About the beginning of September the crop is ripe, which is known by the withering of the leaves; the bulbs are then to be pulled, and exposed on the ground till well dried, and are then to be put away in a store-room, or loft, where they may be perfectly secured from frost and damp.

About the end of August a crop is sown to afford a supply of young onions in the spring months. Those which are not required for the kitchen, if allowed to stand, and if the flower-bud is picked out on its first appearance, and the earth stirred about them, frequently produce bulbs equal in size and quality to the large ones that are imported from the Continent. A crop of very large bulbs may also be secured by sowing about the beginning of September, and transplanting early in spring to very rich soil. Another plan is to sow in May on dry poor soil, when a crop of small bulbs will be produced; these are to be stored in the usual way, and planted in rich soil about February, on ground made firm by treading, in rows about 3 in. apart, the bulbs being set near the surface, and about 6 in. asunder. The White Spanish and Tripoli are good sorts for this purpose.

To obtain a crop of bulbs for pickling, seed should be sown thickly in March, in rather poor soil, the seeds being very thinly covered, and the surface well rolled; these are not to be thinned, but should be pulled and harvested when ripe. The best sorts for this crop are the Silver-skinned, Early Silver-skinned, Nocera and Queen.

Onions may be forced like mustard and cress if required for winter salads, the seeds being sown thickly in boxes which are to be placed in a warm house or frame. The young onions are of course pulled while quite small.

The Potato Onion, Allium cepa var. aggregatum, is propagated by the lateral bulbs, which it throws out, under ground, in considerable numbers. This variety is very prolific, and is useful when other sorts do not keep well. It is sometimes planted about midwinter, and used in salads during the spring and early summer; it is also known as the underground onion, from its habit of producing its bulbs beneath the surface.

The Three Onion or Egyptian Onion, Allium cepa var. proliferum, produces small bulbs instead of flowers, and a few offsets also underground. These small stem bulbs are excellent for pickling.

The Welsh Onion or Ciboule, Allium fistulosum, is a hardy perennial, native of Siberia. It was unknown to the ancients, and must have come into Europe through Russia in the ninth or tenth century. It forms no bulbs, but, on account of its extreme hardiness, is sown in July or early in August, to furnish a reliable supply of young onions for use in salads during the early spring. These bulbless onions are sometimes called Squills, and is also applied to old onions which have stem and leaves but no bulbs.

The following are among the best varieties of onions for various purposes:

_1. Summer and Autumn._—Queen; Early White; Naples; these two sorts also excellent for sowing in autumn for spring salading. Silver-skinned; Tripoli, including Giant Rocca.

_2. For Winter._—Brown Globe, including Magnum Bonum; White Giant; Yerba; Darmstadt; White Giant; Trebons; Trébuns; the finest variety for autumn sowing, attaining a large size early, ripening well, and keeping good till after Christmas; Alisa Craig; Ronsham Park Hero; James’s Keeping; Cranston’s Exterior; Blood Red, strong-flavoured.

_3. For Pickling._—Queen; Early Silver-skinned, White Nocera, Egyptian.

ONOMICRITUS (c. 530–480 B.C.), seer, priest and poet of Attica. His importance lies in his connexion with the religious movements in Attica during the 6th century B.C. He had great influence on the development of the Orphic religion and mysteries, and was said to have composed a poem on initiatory rites. The works of Musaeus, the legendary founder of Orphism in Attica, are said to have been reduced to order (if not actually written) by him (Clem. Alex. Stromata, i. p. 143 [397]; Pausanias, i. 19; 7; 11; 17; 18; 21; 22; 23; 26; 28; 30; 32; 34; 35). He was also employed by Peisistratus to furnish him with oracles encouraging Xerxes to invade Greece and restore the tyrants in Athens (Herodotus viii. 6). He is also said to have been employed by Peisistratus in editing the Homeric poems, and to have introduced interpolations of his own (e.g. a passage in the episode of the visit of Odysseus to the world below). According to Pausanias (viii. 31; 3; 37; 5; ix. 35; 5) he was also the author of poems on mythological subjects.

See F. W. Ritschel, "Onomakritos von Athen," in his Opuscule, i. (1860), and i. 15 of the same volume; U. von Wilamowitz-Moellendorf, "Homerische Untersuchungen" (pp. 190–226 on the Orphic interpolation in Odyssey, λ 566–631), in Kiessling-Möllendorff, Philologische Untersuchungen, Heft 7 (1884).
was estimated as numbering between 1500 and 1700. During the 18th century, the tribe divided, part loyally supporting the Iroquois league, while part, having come under the influence of French missionaries, migrated to the Catholic Iroquois settlements in Canada. Of those who supported the league, the majority, after the War of Independence, settled on a reservation on Grand river, Ontario, where their descendants still are. About 500 are upon the Onondaga reservation in New York state.

ONOSANDER, or ONASANDER, Greek philosopher, lived during the 1st century A.D. He was the author of a commentary on the Republic of Plato, which is lost, but we still possess by him a short but comprehensive work (Στρατηγικός) on the duties of a general. It is dedicated to Quintus Veranius Nepos, consul 49, and legate of Britain. It was the chief authority for the military writings of the emperors Maurice and Leo, and Maurice of Saxony, who consulted it in a French translation, expressed a high opinion of it.

Edition by H. Köchly (1860); see also G. Rathgeber in Ersch and Gruber’s Allgemeine Encyclopädie.

ONSLOW, EARL OF, a title borne by an English family claiming descent from Roger, lord of Oundle in the liberty of Shrewsbury in the 13th century. Richard Onslow (1528-1571), solicitor-general and then Speaker of the House of Commons in the reign of Elizabeth, was grandfather of Sir Richard Onslow (1601-1664), who inherited the family estate on the death of his brother, Sir Thomas Onslow, in 1616. Sir Richard was a member of the Long Parliament, and during the great Rebellion was a colonel in the parliamentary army. He was a member of Cromwell's parliament in 1654 and again in 1656, and was also a member of his House of Lords. His son, Sir Arthur Onslow (1621-1688), succeeded in 1687 by special remainder to the baronetcy of his father-in-law, Sir Thomas Foot, lord mayor of London. Sir Arthur’s son, Sir Richard (1654-1717), was Speaker of the House of Commons from 1708 to 1710, and chancellor of the exchequer in 1715. In 1716 he was created Baron Onslow of Onslow and of Clandon. He was uncle of Arthur Onslow, the famous Speaker (see below), whose only son George became 4th Baron Onslow on the death of his kinsman Richard in October 1776. The 4th baron (1753-1814) had entered parliament in 1754 and was very active in the House of Commons; and in May 1776, just before he succeeded to the family barony, he was created Baron Cranley of Imbercourt. He was comptroller and then treasurer of the royal household, and was present at the marriage of the prince of Wales, afterwards George IV., with Mrs Fitzherbert in 1785. In 1802 he was created Viscount Cranley and earl of Onslow, and he died at his Surrey residence, Clandon Park, on the 7th of May 1814. The second earl was his eldest son Thomas (1754-1827), whose son Arthur George (1777-1870), the 3rd earl, died without surviving male issue in October 1870. He was succeeded by his grand-nephew, William Hillier, 4th earl of Onslow (b. 1853), who was governor of New Zealand from 1888 to 1892; under-secretary for India from 1893 to 1900; and under-secretary for the Colonies from 1900 to 1903. From 1903 to 1905 he was a member of the Conservative cabinet as president of the board of agriculture.

ONSLOW, ARTHUR (1691-1768), English politician, elder son of Foot Onslow (d. 1710), was born at Chelsea on the 1st of October 1691. Educated at Winchester and at Wadham College, Oxford, he had entered in 1720 as a Member of Parliament for the borough of Guildford. Seven years later he became one of the members for Surrey, and he retained this seat until 1761. In 1728 he was elected Speaker of the House of Commons, being the third member of his family to hold this office; he was also chancellor to George II.’s queen, Caroline, and from 1734 to 1742 he was treasurer of the navy. He retired from the position of Speaker and from parliament in 1761, and enjoyed an annuity of £3000 until his death on the 17th of February 1768. As Speaker, Onslow was a conspicuous success, displaying knowledge, tact and firmness in his office; in his leisure hours he was a collector of books.

Speaker Onslow’s nephew, GEORGE ONSLOW (1731-1792), a son of his brother Richard, was a lieutenant-colonel and member of parliament for Guildford from 1760 to 1764. He had a younger brother Richard (1743-1817), who entered the navy and was made an admiral in 1799.

ONTARIO, a province of Canada, having the province of Quebec to the E., the states of New York, Ohio, Michigan, Wisconsin, and Minnesota to the S., Manitoba to the W., and the district of Keewatin with James Bay to the N. In most cases the actual boundary consists of rivers or lakes, the Ottawa to the north-east, the St Lawrence and its chain of lakes and rivers to the south as far as Pigeon river, which separates Ontario from Minnesota. From this a canoe route over small rivers and lakes leads to the Lake-of-the-Woods, which lies between Ontario, Minnesota and Manitoba; and English and Albany rivers with various lakes carry the boundary to James Bay. From Lake Temiscaming northwards the boundary is the meridian of 79° 30’.

Physical Geography.—Ontario extends 1000 m. from E. to W. and more than 700 m. from N. to S., between latitudes 55° and 43°, including the most southerly point in Canada. Its area is 260,862 sq. m. (40,544 water), and it is the most populous of the provinces, nine-tenths of its inhabitants living, however, in one-tenth of its area, being the seacoast and the Lake St Lawrence. This forms part of the plain of the St Lawrence, underlain by Palaeozoic limestones and shales, with some sandstone, all furnishing useful building material and working up into a good soil. The lowest part of the plain, including an area of 4500 sq. m. lying between elevations of 100 and 400 ft., was covered by the sea at the close of the ice Age, which left behind broad deposits of clay and sand with marine shells.

The south-western part is naturally divided into two tracts by the Niagara escarpment, a line of cliffs capped by Ordovician limestones, running from Queenston Heights near the falls of Niagara west to the head of Lake Ontario near Hamilton, and then north-west to the Bruce Peninsula on Georgian Bay. The tract north-east of the escarpment has an area of 9000 sq. m. and an altitude varying from 400 to 1000 ft., and the south-western tract includes 15,000 sq. m. with an elevation of 600 to 700 ft. In the last petroleum, natural gas, salt and gypsum are obtained, but elsewhere in southern Ontario no economic minerals except building materials are obtained.

Covering the higher parts of the south-western Peninsula, the area in most places are rolling hills of boulder clay or stony moraines, while the lower levels are plains gently sloping toward the nearest body of water. The Great Lakes and sheeted with silt deposited in more ancient lakes whose waters have been blocked by ice at the end of the glacial period. The old shore cliffs and gravel bars of these glacial lakes are still well-marked topographical features, and provide favourite sites for towns and cities. London, for example, is built upon the site of one of the outlets of Lake Ontario, and Hamilton and Toronto are on the old shore of Lake Iroquois, the lowest. The Niagara escarpment mentioned above, generally called “the mountain” in Ontario, is the cause of many waterfalls on the rivers and a source of many springs. The Niagara Falls being, of course, the most important; and in most cases these falls have eaten their way back into the tableland, forming deep gorges or canyons like that below Niagara itself, through which the water descends to the ocean in rapid torrents at the point where it leaves the Finger Lakes area at Fort Erie, and on to the Bay to the north of the region just referred to, there is a southward projection of the Archæan protaxis consisting of granite and gneiss of the Laurentian, enclosing bands of crystalline limestone and phyllites as far west as the only mines of "Old Ontario." From these rocks in the Ottawa valley are quarried or mined granite, marble, magnificent blue sodalite, felspar, talc, actinolite, mica, apatite, graphite and conurbans; the latter mineral, which occurs on a large scale here than elsewhere in the province. A large area of copper and iron is located in Lorrainian and Huronian rocks of the Archæan protaxis. The rocky hills of the tableland to the north long regressed settlement, the region being looked on by the thrifty farmers of the south as a wilderness of woods and for their forests and its furs; and unfortunate settlers who ventured into it usually failed and went west or south in search of better land. Gradually, however, areas of good soil were opened.
ONTARIO

up, in the Rainy river valley, near Lake Temiscaming and elsewhere, and mines of various kinds were discovered, as the Canadian Pacific railway and its branches extended through the region, and at length the finding of very rich silver mines attracted world-wide attention to northern Ontario. In the better explored parts along the highways, the rivers, and the railroads, ores of gold, silver, nickel, cobalt, antimony, arsenic, bismuth and molybdenum have been obtained, and several important mines have been opened up. Gold has been found at many points across the whole province, from the mines of the Lake Temiscaming region to the western portion of the north-west; but in most cases the returns have been unsatisfactory, and only a few of the gold mines are working. Silver mines have proved of far greater importance, in early days near Thunder Bay on Lake Superior, more recently in the interesting region of the lake of the same name, at the north-west corner of the province. The silver from the ore running sometimes several thousand ounces per ton, output being 5,000,000 oz, in 1906. Associated with the silver minerals are rich ores of cobalt and nickel, combined with arsenic, antimony and sulphur, which would be considered valuable if occurring alone, but are not paid for under present conditions, since they are difficult to separate and refine. The cobalt silver ores are found mainly in Huronian conglomerate, but also in older Keewatin rocks and younger diamictic deposits. The first of these is about 20 miles south of Sudbury; and the second, a few square miles, is found to extend 25 m. to the west and as much to the north. Up to the present the most important mineral product of Ontario is nickel, which is mined only in the neighbourhood of Sudbury, where the ores contain on the average 6% nickel. In 1906 produced 9934 tons. more than half of the world's supply of the metal. With the nickel copper is always found, and copper ores are worked on their own account in a few localities, such as Bruce mines. Iron ores have been worked in the region of the Keewatin, but nowhere in amounts comparable with those of the same formation in Michigan and Minnesota. The total ore output of Ontario, including building materials and cement, is larger than that of gold, silver and other minerals combined. Probably the most important ore deposit, which is carried on in the northern part of the province, doubt many more deposits of value will be discovered. It has been found that northern Ontario beyond the divide between the Great Lakes and Hudson Bay produces small flumes which in the warm days of summer expand the post-glacial lake, like those in the southern part of the province, running from east to west from Lake Abitibi to a point north of Lake Nipigon. Railways are opening up this tract. The clay belt in lake Superior south of the lakes, covering much of the area of great value, compensating for the labour of clearing the land.

Lakes and Rivers.—All parts of Ontario are well provided with lakes and rivers, the most important being that of the St Lawrence and the Great Lakes with their tributaries, which drain the more populous southern districts, and, with the aid of canals, furnish communication by fairly large vessels between the lower St Lawrence and Superior and also (via the St Clair river) with the lakes of Michigan and Huron. The Saint Lawrence system of lakes has been navigable for water traffic for 225 ft. above the sea, 70 m. long and 50 m. wide, may be looked upon as the headwaters of the St Lawrence, since Nipigon river is the largest tributary of Lake Superior, though several other important rivers, such as the Kaministikua, the Pic and the Manistiniqua, and the Mackinac river to the north. All these rivers have high falls not far from Lake Superior, and Kakebec Falls on the Kaministikua supplies power to the twin cities of Fort William and Port Arthur, while the deep water of Lake Superior makes the great lake the port of the west during the summer. The north shore of Lake Superior is bold and rugged with many islands, such as Ignace and Michipicoten, but with very few settlements, except fishing stations, owing to its rocky character. The south-eastern part of Lake Huron is separated from Lake Superior by a fall of 225 ft. along the Sault Saint Marie waterway to the Huron, the rest of which takes place at Sault Saint Marie, where the largest locks in the world permit vessels of 10,000 tons to pass from Lake Superior to the south and, where water-power has been largely developed in the roller mills and other industrial plants on both sides of the lakes. The north-eastern parts of Lake Huron and its large expansion Georgian Bay are fringed with thousands of islands, mostly small, but one of them, Manitoulin Island, is 80 m. long and 30 m. broad. French river, the outlet, is a large lake, 30 m. long, 10 m. wide, draining directly into Georgian Bay. In the north part of the province lie the Manitoulin Island and the mouth of Georgian Bay near the points of the intersection of the St Clair river with the Grand River, which is cut off from the main lake by Manitoulin Island and the long promontory of Bruce Peninsula. Lakes Superior and Huron both reach depths of hundreds of feet below sea-level, but the next lake, at the southern end, St Clair, which Lake Huron drains southward through St Clair river, is very shallow and marshy. Detroit river connects Lake St Clair with Lake Erie at an elevation of 157 ft. and this comparatively shallow lake, running for 225 m. east and west, empties northward where Niagara river into Lake Ontario, which is only 14 ft. above the sea, Niagra Falls, with rapids above and below, carry the waters of the upper lakes over the Niagara escarpment. Power from the falls is put to use in New York state and Ontario, a large amount being sent to Toronto 80 m. away. Welland canal, between Port Colborne on Lake Erie and Dalhousie on Lake Ontario, carries vessels of 14 ft. draught from one lake to the other. From Lake Ontario the St Lawrence emerges through the meshes of the Thousand Islands, where it crosses Archatean rocks, after which follow several rapids separated by quieter stretches before Montreal is reached at the head of ocean navigation. Steamers not of too great draught can run the rapids going down, but vessels must come up through the canals. All the other rivers in southern Ontario are tributaries of the lakes of the St Lawrence system and, when they enter it, must be the largest, and the Trent next in importance. In northern Ontario lakes are innumerable and often very picturesque, forming favourite summer resorts, such as Lake Temagami, the Muskoka Lakes and Lake-of-the-Woods. The latter lake with Rainy Lake and other connected bodies of water beside the Hudson Bay system of waters, their outlet being by Winnipeg river to Lake Winnipeg, from which flows Nelson river. In Ontario the Albany, Moose, Missanabi and Abitibi flow into Hudson Bay, but none of these rivers is navigable except for canoes.

Climate.—The climate of Ontario varies greatly, as might be expected from its wide range in latitude and the relationships of the Great Lakes to the southern peninsula of the province. The northern parts are far south as the north shore of Lake Superior and have long and cold but bright winters, sometimes with temperatures reaching 50° F. below zero; while their summers are delightful, with much sunshine and some hot days but pleasantly cool nights. Between Georgian Gulf and Lake Ontario the winters are colder but less bright, with a plentiful rainfall and cold snowfall; while the summers are warm and sometimes even hazy. The south-west peninsula of Ontario has its climate greatly modified by the lakes which almost enclose it. As the lakes never freeze, the prevalent cold north-westerly winds are less felt than in areas where there is a passage over them, and often much of the winter precipitation is in the form of snow, so that the weather has much less certainty than in the north. The summers are often sultry, though the presence of the lakes prevents the interior heat experienced in the east and west. Owing to the mildness of its winters, the south-west peninsula is a famous fruit country with many vineyards and orchards of apples, peaches and pears. Indian corn (maize) is an important field crop, and tobacco is cultivated on a large scale. Sweets and apples are shipped to the large American markets and for canning, giving rise to an important industry. The normal temperatures (Fahr.) for three points in the south-western, eastern and north-western portions are given below:—

1 The name given to the rural municipalities.
2 Any town in Canada can become incorporated as a city on attaining a population of 10,000.

Ontario is thus pre-eminently an agricultural province, though the growth of manufactures has increased the importance of the towns and cities, and many of the farmers are seeking new homes in the provinces of Manitoba, Alberta and Saskatchewan. This emigration accounts in large measure for the slow increase of the population, though there has also been a slight decrease in the birth-rate. The population was long entirely confined to the southern and eastern sections of the province, which comprise an area of about 33,000 sq. m.; but in these districts it is now stationary or decreasing, whereas the northern and western portions are filling up rapidly. Toronto, the provincial capital, has grown from 59,000 in 1871 to about 300,000, partly through the absorption of neighbouring towns and villages. Other
important cities are Ottawa (the capital of the Dominion) (39,028 in 1911), Hamilton (52,634), London (37,981), Kingston (17,061). The number of males slightly exceeds that of females. The population of Canada consists of the following races: French, English, German, Irish, Scotch, American, Italian, Greek, Spanish, and Portuguese. The French are largely distributed in the eastern provinces, and the English are predominant throughout the United Dominion. The number of females is nearly equal to that of males, the latter, however, predominating in the United Provinces, and the former in the British Dominion.

The population of the Dominion of Canada consists of four groups: British, French, and American, with a small number of Indians and Metis. The British population is divided into three classes: United Province, or British, and French. The French population is divided into two classes: United Province, or French, and British. The American population is divided into two classes: United Province, or American, and British.

The municipal system of Canada is regulated by the laws of the Dominion, which are in force in all the provinces. The Dominion has the power to make laws for the peace, order, and good government of the Dominion, and to subject the provinces to the same regulations. The provincial governments have the power to make laws for the peace, order, and good government of their respective provinces, and to subject the municipalities within their jurisdiction to such regulations as may be necessary for the proper administration of the laws of the province.

horses and sheep is stationary or declining, but the raising of hogs, formerly abandoned in great part to the western states, is becoming an increasing industry. Large quantities of peas, corn, tomatoes and other vegetables are canned, chiefly for home consumption. Three-quarters of the orchard lands of Canada are devoted to peaches and pears. The cultivation of the latter in the Niagara peninsula, but apples flourish along the great lakes and the St. Lawrence from Goderich to Cornwall. In Essex and Kent, and along the shore of Lake Erie, tobacco and grapes form important crops. The value of farmers' produce is increasing. Lumber.—Slightly less than half remains of the forest which once covered the whole province. The lumber industry exceeds that of any other part of the Dominion, though Quebec possesses greater timber area. The mountain forest is almost untouched and from this it facilitates the bringing of the timber to market. All trees were long little thought of in comparison with the pine, but of late years poplar and spruce have proved of great value in the making of pulp, paper, and masonite. Softwood, as a building material, is becoming increasingly valuable for use in flooring and the making of furniture. In the spring the making of syrup and sugar from the sap of the sugar-maple is a typical industry.

Much splendid timber has been needlessly destroyed, chiefly by foresters, but also by improvident farmers in their haste to clear the land. Increased attention is now being paid by both provincial and federal governments to preservation and to reforestation. Special areas have been set apart on which the owner and his descendants may plant as many trees per acre as the species of specific forestry may be studied. Of these, the earliest was the Algomaquin National Park, which also forms a haven of refuge for the wild creatures.

Northern Ontario is still a valuable fur-bearing and hunting country, and fox, beaver, mink and skunk being found in large quantities. Wolves, once numerous, have now been almost extirpated, though a bounty on each head is still paid.

Minerals.—The geographical distribution of the great mineral wealth is indicated (see Physical Geography, above). Save for beds of lignite, said to exist in the extreme north, coal is not found and has to be imported, chiefly from the states of Ohio and Pennsylvania, though Nova Scotia furnishes an increasing quantity yearly. The iron ore mined and exported by the governments is largely that of the neighbourhood of Sudbury.

The province supplies over two-thirds of the iron ore mined in the Dominion, but much is still imported. The output of gold is decreasing. The nickel mines in the neighbourhood of Sault Ste-Marie are the greatest in the world, and the gold fields in the vicinity of Sudbury are of great importance. Cobalt, the centre of this area, is 103 m. from North Bay by the provincial railway (Temiscaming & North Ontario railway). In the same neighbourhood are found cobalt, arsenic and bismuth. In the older districts of the province where the timber may be cut, the district around Petrolia produces about 30,000,000 gallons of petroleum yearly, practically the whole output of the province. Salt is worked in the vicinity of Lake Huron, but the production is less than half that imported. Natural gas is produced in the counties of West Grey and Grey and in physicians' offices in Toronto and Buffalo. Among the less important metals and minerals which are also mined, is corundum of especial purity.

Manufactures and Commerce.—Manufactures are becoming of increasing importance. The obstacle due to lack of coal is offset by the splendid water powers afforded by the rapid streams in all parts of the province. Save for the flour and grist mills, few do more than supply the markets of the Dominion, of which they control an increasing portion. Woolen mills, distilleries and breweries and manufacturers of leather, locomotives and iron-work, furniture, agricultural implements, cloth and paper are the chief. The great agricultural development of the western provinces, in manufactures, is felt. Little, if anything, has been lost to the industries of the older provinces, especially Ontario.

Communications.—Numerous lakes and rivers afford means of communication, and obstacles thereon have been largely overcome by the building of canals and of navigable railways. The province contains one-third the total mileage of the dominion; their construction is aided by provincial and municipal subsidies, in addition to that paid by the federal government. The provincial government owns a line running north from North Bay, operated by a board of commissioners. The line may be worked by the provincial companies, but are subject to the decisions of a federal railway commission. The provincial railway and municipal board also exercises control, especially over the city and suburban electric lines.

History.—The first white man known to have set foot in what is now Ontario was Champlain. In 1613 he explored the Ottawa river as far as Alumette Island; in 1615, starting from Montreal, he reached the Georgian Bay by way of the Ottawa river, Lake Nipissing and French river, and then by way of Lakes Couchiching and Simcoe and the Trent river system of lakes and streams made his way to Lake Ontario, called by him Entouchorone. The winter of 1615-1616 he spent among the Huron Indians, near the Georgian Bay. In 1616 a mission among these Indians was founded by the Recollet friars, and carried on with great success and devotion by the Jesuits, but in 1648-1650 the Huron nation was almost utterly destroyed by an invasion of their hereditary foes, the Iroquois. From its centre at Quebec French civilization extended along the Mississippi and the Great Lakes, and also northwards to Hudson’s Bay. In the western country numerous posts were founded, wherein fur-trader and missionary were often at variance, the trader finding brandy his best medium of exchange, while the missionary tried in vain to stay its ravages among his flock. On the frontiers of what is now Ontario the chief points were at the strategic centres of Fort Frontenac (now Kingston), Niagara, Michilimackinac and Sault-Ste-Marie. Farther north, in what is now New Ontario, their English rivals, the Hudson’s Bay Company, had more or less permanent posts, especially at Fort Albany and Moose Factory.

With the cession of French North America to Great Britain in 1763, the Indian lords of the soil rose under Pontiac in a last attempt to shake off the white man, and in 1765-1766 there was hard fighting along the western frontier from Sault Ste-Marie to Detroit. Thereafter for almost twenty years, Ontario was traversed only by wandering bands of trappers, chiefly belonging to the Hudson’s Bay Company; but in 1782 bands of American loyalists began to occupy the fertile country along the Bay of Quinté, and in the Niagara peninsula, the first settlement being made in 1782 at Kingston. Between 1782-1784 about 5000 loyalists entered Ontario, and were given liberal grants of land by the British government.

The oligarchic constitution established in Canada in 1774 by the Quebec Act did not suit men trained in the school of local self-government which Britain had unwittingly established in the American colonies, and the gift of representative institutions was soon necessary. In the debates in the British parliament Fox urged that the whole territory should remain one province, and of this the governor-general, the 1st baron Dorchester (q.v.), was on the whole in favour, but in 1791 Pitt introduced and carried the Constitutional Act, by which Upper and Lower Canada were separated. The Ottawa river was chosen as the main boundary between them, but the retention by Lower Canada of the seigneuries of New Longueil and Vaudreuil, on the western side of the river, is a curious instance of the triumph of social and historical conditions over geographical. To the new province were given English civil and criminal law, a legislative assembly and council and a lieutenant-governor; in the words of its first governor, Colonel John Graves Simcoe, it had, “the British Constitution, and all the forms which secure and maintain it.” Simcoe set to work with great energy to develop the province, but he quarrelled with the governor-general over his pet scheme of founding military colonies of retired soldiers in different parts of the province, and retired in 1796. Even before his retirement political feuds had broken out, which increased in bitterness year by year. In so far as these had other causes than the Anglo-Saxon love of faction, they were due to the formation by the loyalists, their descendants and hangers-on of a clique which more and more engrossed political and social power. The English church also formed a quasi-official clerical oligarchy, and the land reserved by the Constitutional Act for the support of “a protestant clergy” formed a fruitful source of bitterness.

For a time the War of 1812-1814 with the United States put an end to the strife. The war gave some heroic traditions to the province, and in special cemented that loyalty to Great Britain for which Ontario has been conspicuous. On the other hand, the natural dislike of the United States felt by the loyalists and their descendants was deepened and broadened, and has not yet wholly died away, especially among the women of the province. The jobbing of land by the official clique, whose frequent inter-marriages won for them the name of “The Family Compact,” the undoubted grievance of the “Clergy Reserves” and the well-meaning high-handedness and social exclusiveness of military governors, who tried hard but unavailingly to stay the democratic wave, soon revived political discord, which found a voice in
that born agitator, William Lyon Mackenzie. A wiser but less vigorous reformer was Robert Baldwin, who saw that in responsible government the political law lay the formula for the political green-sickness from which Upper Canada was suffering. But though Baldwin and Mackenzie were in the right, it is very doubtful whether their party could at the time have given the country as cheap and efficient a civil service as was given by the Family Compact, who had at least education and an honourable tradition.

In 1837 discontent flared up into a pitiful little rebellion, led by Mackenzie. This tragic farce was soon at an end and its author a fugitive in the United States, whence he instigated bands of hooligans to make piratical attacks upon the Canadian frontier. Thus forcibly reminded of the existence of Canada, the British government sent out Lord Durham to investigate, and as a result of his report the two Canadas were in 1841 united in a legislative union.

Meanwhile the southern part of the province had been filling up. In 1791 the population was probably under 20,000; in 1824 it was 150,000, and in 1841, 455,688. The eastern counties of Stormont and Glengarry, and parts of the western peninsula, had been settled by Highlanders; the Canada Company, organized in 1825 by the Scottish novelist, John Galt, had founded the town of Guelph, which had cleared large tracts of land in the western peninsula, and settled thereon hundreds of the best class of English and Scotch settlers.

Once granted responsible government, and the liberty to make her own mistakes, Upper Canada went ahead. The population rose to 952,004 in 1851 and to 1,396,091 in 1861. Politically she found Lower Canada an uneasy yoke-fellow. The equality of representation, granted at the union, was soon unfair to Lower Canada, as her population first equaled and then surpassed that of her sister province. The Roman Catholic claim to separate state-aided schools, at length conceded in 1863, long set the religious bodies by the ears. Materially the province prospered. The Clergy Reserves were secularized in 1854, and in 1857 began a railway development, the excitement and extravagance caused by which led in 1857 to a financial crisis and the bankruptcy of many municipalities, which, but which the whole produced great and lasting benefit. The Reciprocity Treaty with the United States, in operation from 1854 to 1866, and the high prices for farm produce due to the American Civil War, brought about an almost hectic prosperity. In the discussions from which sprang the federation of 1867, Ontario was the one province strongly in favour of the union, which was only rendered possible by the coalition of her rival leaders, J. A. Macdonald and George Brown.

Since Federation Upper Canada has been known as the province of Ontario. The first provincial government, formed on coalition lines by John Sandfield Macdonald, was thrifty and not unprofitable, but in 1871 was defeated by a reorganized liberal party, which held power from 1871 to 1905, and on the whole worthy. Under Oliver Mowat, premier from 1873 to 1896, the government, though strongly partisan, was thrifty and honest. An excellent system of secondary schools was organized by 1878-79, and Mowat, a university graduate, was, with G. W. Ross, the first to see the necessity of a university and of higher education in the capital. In 1887 a more thorough reorganization, an act of incorporation invested the University of Toronto with the new name of the University of Toronto; an act of incorporation created a faculty of law, a faculty of arts, and a faculty of science; an act of incorporation enabled the university to confer degrees of bachelor of arts and of arts and sciences; and an act of incorporation passed by the legislature of the province of Ontario provided for the establishment of a university in the city of Toronto, and for the incorporation thereof with the university of Toronto as the corporation of the University of Toronto.

The great struggle of the time was with the federal government on the question of provincial rights. Several questions in which Ontario and the Dominion came into conflict were carried to the Judicial Committee of the Privy Council, and in all of them Mowat was successful. Connected with this was the boundary struggle with Manitoba, the latter province being aided by the federal government, partly out of dislike for Mowat, partly because the crown lands in the disputed territory would, had it been adjudged to Manitoba, have been under federal control. Had Manitoba won, the boundary line would have been drawn about 6 m. east of Port Arthur, but in 1884 the Judicial Committee of the Privy Council unanimously decided in favour of Ontario; and in 1888 another decision gave her absolute control of the crown lands of New Ontario. Under Mowat’s successors the barnacles which always attach to a party long in power began to seem unpleasantly conspicuous, and in January 1905 the conscience of Ontario sent the conservatives into power, more from disgust at their opponents than from any enthusiasm for themselves. The new government displayed unexpected energy, ability and strength. The primary and model schools were consolidated and improved; the provincial university was given increased aid from the succession duties; various public utilities, previously operated by private companies, were taken over by the province, and worked with vigour and success. At the election of the 8th of June 1908 the conservative government was returned by an increased majority.

BIBLIOGRAPHY.—Statistical: The various departments of the provincial government publish annual reports, and frequent special reports. Among these may be noted those of the Bureau of Mines and the archaeological reports by David Boyle (1866-1900). Since 1880 the university of Toronto has published numerous valuable studies on historical, economic and social questions, e.g. Adam Shortt, _Municipal Government in Ontario_.

Historical: The early history of the province is best given in the general histories of Canada by MacMullen and Kingsford (see CANADA). Ernest Cruikshanks has published numerous excellent studies on the Ontario section of the War of 1812. Lord Durham’s _Confederation_ (1839) and _Lamentations over Ontario_ (1867) are excellent. Ontario is primarily a history of the province from 1867 to 1896. The provincial government has issued an excellent _Documentary History of Education in Ontario_, by J. G. Hodges (28 vols.). See also W. Kingsford, _Early Bibliography of Ontario_.

ONTARIO, LAKE, the smallest and most easterly of the Great Lakes of North America. It lies between 43° 11' and 44° 12' N. and 76° 12' and 79° 49' W., and is bounded on the N. by the province of Ontario and on the S. by the state of New York. It is roughly elliptical, its major axis, 180 m. long, lying nearly east and west, and its greatest breadth is 53 m. The area of its water surface is 7,690 sq. m. and the total area of its basin 32,890 sq. m. Its greatest depth is 735 ft., its average depth much in excess of that of Lake Erie, and it is as a general rule free from unfavourable shoals or dangers.

On the north side of the lake the land rises gradually from the shore, and spreads out into broad plains, which are thickly settled by farmers. A marked feature of the topography of the south shore is what is known as the Lake ridge, or, as it approaches the Niagara river, the Mountain ridge. This ridge extends, with breaks, from Sodus to the Niagara river, and is distant from the lake 3 to 8 m. The low ground between it and the shore, and between the Niagara escarpment and the water on the Canadian shore, is a celebrated fruit growing district, covered with vineyards, peach, apple and pear orchards and fruit farms. The Niagara river is the main feeder of the lake; the other largest rivers emptying into the lake are the Genesee, Oswego and Black from the south side, and the Trent, which discharges into the upper end of the bay of Quinte, a picturesque inlet 70 m. long, on the north shore, at the mouth of the river, Prince Edward, near the eastern extremity of the lake, and the main land. The lake is separated from Lake Huron by the island of Manitoulin and five islands, and the lake has its outlet near Kingston, where it discharges into the head of the St. Lawrence river between a group of islands. Elsewhere the lake is practically free from islands. There is a general surface current down the lake towards the eastward of about 8 m. a day, strongest along the south shore, but no noticeable return current. As a result of its relatively great depth there are seldom any great fluctuations of level in this lake due to wind disturbance, but the lake follows the general rule of the Great Lakes (g.s.) of seasonal and annual variation. Standard high water (of 1876) is 27-77 ft. below the mean level, of 246-18 ft. above mean sea-level, and standard low water 3-24 ft. below the same plane. The lake never freezes over, and is less obstructed by ice than the other lakes, but the harbours are closed by ice from about the middle of December to the middle of April.

The commerce of Lake Ontario is limited in comparison with that of the lakes above Niagara Falls, and is restricted to vessels
that can pass through the Welland canal locks, which are 270 ft. long, 45 ft. wide and 14 ft. deep. Freight consists principally of coal shipped from Charlotte, Great and Little Soda basins and Oswego to Canadian ports in the lakes, and to ports on the St Lawrence river; of grain shipped through the Welland canal to the St Lawrence; and of lumber from Canadian ports. There is a large passenger traffic, including pleasure trips, principally radiating from Toronto. Ports on the lake are limited in capacity to vessels drawing not more than 14 ft. of water. The principal Canadian ports are Kingston, at the head of the St Lawrence river; Toronto, where the harbour is formed by an island with improved entrance channels constructed both east and west of it; and Hamilton, at the head of the lake, situated on a landlocked lagoon, connected with the main lake by Burlington channel, an artificial cut. The principal United States port is Oswego, where a breakwater has been built, making an outer harbour. The construction of a breakwater was undertaken in 1907 by the United States government at Cape Vincent to form a harbour where westbound vessels can shelter from storm before crossing the lake.

The difference of 327 ft. in level between Lake Ontario and Lake Erie is overcome by the Welland canal, which leads southward from Port Dhalhouse. It accommodates vessels 255 ft. in length, with a draught of 14 ft. The Murray canal, opened for traffic on the 14th of April 1890, extends from Presqu'ile bay, on the north of the lake, to the head of the bay of Quinte, and enables vessels to avoid 70 m. of open navigation. It is 11 ft. deep below the lowest lake level, and has no locks. It is proposed to have the eastern terminus of the Trent canal system (see Great Lakes) at the head of the bay of Quinte, entering through the Trent river. At Kingston the Rideau canal, extending 128 m. to Ottawa, enters the St Lawrence river at the foot of the lake.

ONTENIENTE (Gr. ὄντι, ὄντος, pres. part. of ὄνειρος, to be, and ὄνος, science), the name given to that branch of philosophy which deals specially with the nature of being (ὁμοίων) i.e. reality in the abstract. The idea, denoted in modern philosophy by the term "ontology" in contrast to the broader "metaphysics" and the correlative "epistemology," goes back to such phrases as ὀνοματολογία, which Plato uses to describe the absolute reality of ideas; Plato, however, uses the term "dialectic" for this particular branch of metaphysics. Aristotle, likewise, holding that the separate sciences have each their own subject matter, postulates a prior science of existence in general which he describes as "first philosophy." So far, therefore, the science of being is distinguished not from that of knowing but from that of the special forms of being; as to the possibility of objective reality there is no question. A new distinction arises in the philosophy of Wolff who first made "ontology" a technical term. Theoretical philosophy (metaphysics) is by him divided into that which deals with being in general whether objective or subjective, and contrasted with the particular entities, the soul, the world and God. The former is ontology. This intermediate stage in the evolution of the science of being gave place to the modern view that the first duty of the philosopher is to consider knowledge itself (see Epistemology), and that only in the light of conclusion as to this primary problem it is possible to consider

the nature of being. The evolution of metaphysics has thus relegated ontology to a secondary place. On the other hand it seems true that a science of being is inseparable from, and in a sense identical with, that of being. Epistemological conclusions cannot be expressed ultimately without the aid of ontological terms.

For the wider relations of ontology, see further Philosophy.

ONYX, a banded chalcedony or striped agate, composed of white layers alternating with others of black, brown or red colour. A typical onyx consists of two or more black and white strata, whilst the term sardonyx is applied to the stone if it contains red or brown bands (see SARDONYX). Probably those varieties which show red and white zones originally suggested the name "onyx," from Gr. ὄνυξ (a fingernail), since the colours of such stones may be not unlike those of the nail. The onyx when worked by the lapidary was often designated by the diminutive ὄνυχος; and at the present day the term nicolo, a corruption of the Italian diminutive onycalo, is applied to an onyx which presents a thin layer of chalcedony deriving a bluish tint from the subject incident ground. The Hebrew sohams is translated in the authorized version of the Old Testament "onyx," but the revised version gives in some of the passages an alternative marginal reading of "beryl." The position of the land of Havilah, which yielded the onyx-stone, is uncertain.

India has for ages supplied the finest onyxes, and hence jewelers apply the expression "Oriental onyx" to any stone remarkable for beauty of colour and regularity of stratification, quite regardless of its locality. As far back as the 1st century the author of the Periplus Maris Erythraei mentions the onyx among the products of Plythanae, a locality probably identified with Paithan on the Godavari; and he further states that the stones were taken down to Barygaza, the modern Brouch, where the agate trade still flourishes. It is probable that the early Greeks and Romans derived their prized agate-cups from this locality. The Indian onyx is found, with agate and jasper, in river gravels derived from the disintegration of the amygdaloidal volcanic rocks of the Deccan. A great deal of onyx now sold is obtained from South American agates, cut in Germany. It often happens that the lower deposits in an agate-nodule are in horizontal layers, forming onyx, while the other deposits have adapted themselves to the curved contours of the cavity. The onyxes cut from agate-nodules are usually stained artificially, as explained under AGATE.

The onyx is largely used for beads, brooches, pins, ring-stones and other small ornamental objects, while the larger pieces are occasionally wrought in the form of cups, bowls, vases, &c. Onyx is the favourite stone for cameo work, advantage being taken of the differently-coloured layers to produce a subject in relief on a background of another colour. For fine examples of ancient cameo-work in onyx and sardonyx see GEM.

It should be noted that the term onyx, or onychite, was formerly, and is still sometimes, applied to certain kinds of banded or striped agates, like the "oriental alabaster" (see AVABASTER). Such substances are quite distinct from the hard, siliceous onyx, being much softer and less precious: they are, in fact, usually deposits of calcium carbonate like stalagmite and travertine. The ornamental stones known as Mexican onyx, or Teci marble, and Algerian onyx are of this character; and in order to avoid any confusion with the true onyx it is well to distinguish all the calcareous "onyxes" as onyx-marble. The well-known "Gibraltar stone" is an onyx-marble, with brown bands, from caverns in the limestone of Gibraltar. The Teci onyx, sometimes with delicate green shades, takes its name from the district of Teci; one of its localities being La Pedrera, about 21 m. from the city of Puebla.

F. W. R.*

OLITE (Gr. ὄλιθος, egg, τάξις, stone), in geology, a term having two distinct meanings. In petrology (q.v.) it denotes a type of rock structure characterized by the presence of minute spherical granules resembling the roe of a fish; if the grains become larger, the structure is said to be psilotic (Gr. πεισλόες, pea). In
OOLITE

119

The basal sandy series, which is closely related with the underlying Lias, is usually described as the Midford Sands (from Midford, near Bath), but it is also known locally as the Bradford, Yeovil or Cotteswold Sands. The Pea Grt series contains pisolithic limestone and coarse, iron-stained oolite and sandy limestone. The freestones are compact oolite limestones. The ragstones are fossiliferous, earthy and iron-stained oolitic limestones. The “grits” are really coarse-grained limestones or calciferous sandstones. Between Andoversford and Bourton-in-the-Water the Inferior Oolite is represented by ragstones (Ferruginous beds, Clayey Grit, Trigonia bed, Notgrove Freestone, Gryphite Grit) and freestones (Upper Freestone sands and Harford Sands, Oolite Marl, Lower Freestone). Near Chipping Norton in Oxfordshire the “Chipping Norton Limestone” lies at the top of a very variable series of rocks. In Rutlandshire, Northamptonshire and Lincolnshire the following beds, in descending order, belong to the Inferior Oolite: Lincolnshire limestone (shelly, coralline and oolitic), Collyweston slate, Lower Estuarine series and Northampton Sands (hard calcareous sandstones, blue and greenish ironstones and sandy limestones). The Collyweston slates are arenaceous limestones which have been used for roofing slates since the time of Henry VII.; Easton, Dene and Kirkby are important localities. The fissility of the rock is developed by exposure to frost. Similar beds are the Whittington Pendle and White Pendle or Dunstan slate.

The Inferior Oolite of Yorkshire differs from that of the Cotteswold district; in place of the marine limestones of the latter area there is a thick series of sands and sandstones with shales and beds of coal; these deposits are mainly estuarine with occasional marine beds. The principal subdivisions, in descending order, are: the Scarborough or Grey Limestone series, the Middle Estuarine series with their coal seams; the Millpool series and Whitwell or Cave Oolite; the Lower Estuarine series with the Eller Beck bed and Hydraulic Limestone; the Dogger and Blea Wyke beds. The last-named beds, like the Midford Sands, exhibit a passage between the Inferior Oolite and the Lias. In Skye and Raasay the Inferior Oolite is represented by sandstones.

The fossils of the Inferior Oolite are abundant. Over 200 species of Ammonite are known; gastropods are numerous: Trigonites, Lima, Ostrea, Geraula, Pecten, are common pelecypods; Terebratula, Waldehaemia, and Trigonia are the prevailing brachiopods. Corals are very numerous in some limestones (Isastera, Montevallina). Urchins are represented by Cidaris, Acrosolen, Nuculodites, Pygaster, Pseudolamellia, Hexacrinus; starfish by Solaster, Astreopeten, and Corals by the genus Trigonia, Aplocorina. Plant remains, cycads, ferns, Ginkgo and coniferous trees are found most abundantly in the Yorkshire area.

The economic products of the Inferior Oolite include many well-known building stones, notably those of Ham Hill, Doulting, Dundry, Painswick, Cheltenham, Duston, Weldon, Ketton, Barnack, Stamford, Casterton, Clipsham, Great Ponton, Ancaster, Aisleby (Lower Estuarine series). Several of the stones are used for road metal. Iron ores have been worked in the Great Limestone, the Eller Beck bed, the Dogger and the Northampton beds, the latter being the most important.

The Great or Bath Oolite is typically developed in the neighbourhood of Bath, and except in a modified form it does not extend into the counties of Somersetshire, Gloucestershire and Oxfordshire. It does not reach so far as Yorkshire, unless the Upper Estuarine series of that district is its representative. The principal subdivisions of the series are:

An exact correlation of the Great Oolite strata in the N.E. area with those of the S.W. is not possible on account of the great variability and imper sistence of the beds. Current bedding is very prevalent, and minor stratigraphical breaks are common. The absence of the typical Great Oolite from the N.E. district is probably due in part to contemporaneous erosion with overstep of the succeeding formation, and in part to local changes in the sediment in the shallow waters of this epoch. This may also explain the rapid thinning-out of the Great Oolite south of Bath, where its place may be taken, to some extent, by the Bradford Clay, Forest Marble and Fullonian.

The Great Oolite is not readily divisible into palaeontological zones, but the ammonite Perisphinctes arbusitigerus may be taken as the characteristic form along with Belemnites bessinian and Terebratula mastiliana. Corals (Isastera, Thamnasteria) and Polyzoa (Strophasteria, Dystrotopus) are abundant. Hemidiscus, Cidaris, Acrosolen, Crania, Clayey and oolitic urchins are common: Pentacrinus and Aplocorina represent the Crinoids. Terebratula, Rhychonella, Waldehaemia, Crania are the prevailing brachiopods; the common pelecypods, Pecten, Ostrea, Lima, Trigonia, Modiolus; Nautilia, Nemosites and other gastropods are found. Perisphinctes grandis, Macrocephalites subcontractus, Oppelia disius and Nautilus disius are among the more common cephalopods. The remains of fish (Mesorodon, Ilyodus), crocodiles (Teleosaurus), dinosaurs (Cetiosaurus,

OPALINA—OPERA

have been carried on for centuries in the mountains near Eperjes, and some remarkable stones from this locality are preserved in the Imperial Natural History Museum in Vienna, including an uncut specimen weighing about 5000 carats. Precious opal is found also in Honduras, especially in trachyte near Gracias á Dios; and in Mexico, where it occurs in a porphyritic rock at Esperanza in the state of Queretaro. A remarkable kind of opal, of yellow or hyacinth-red color, occurs in trachytic porphyry at Zimapan in Hidalgo, Mexico, and is known as "fire-opal." This variety is not only cut en cabochon but is also faceted. Fire-opal is sometimes called "girasol." Much precious opal is worked in Australia. In Queensland it is found lining cracks in nodules of brown ironstone in the Desert Sandstone, a rock of Upper Cretaceous age, and is distributed over a wide area near the Barcoo river. Bulla Creek is a well-known locality. The layer of opal, when too thin to be cut with a convex surface, is used for inlaid work or is carved into cameos which show to much advantage against the dark-brown matrix. The matrix penetrated by veins and spots of opal, and perhaps heightened in color artificially, has been called "black opal"; but true black opal occurs in New South Wales. The "root" of opal consists of the mineral disseminated through the matrix. In New South Wales precious opal was first found in 1881, and is now largely worked at White Cliffs, Yungamgra county, where it is found in nodules and seams in a siliceous rock of the Upper Cretaceous series. It is notable that the opal sometimes replaces shells and even reptilian bones, whilst curious pseudomorphs, known as "pineapple opal," show the opal in the form of aggregated crystals, perhaps of gypsum, pyromus or glauberite. Common opal is the name generally applied to the varieties which exhibit no beauty of color, and may be nearly opaque. It is frequently found in the vesicular lavas of the N.E. of Ireland, the west of Scotland, the Faroe Isles and Iceland. When of milky-white color it is known as "milky opal"; when of resinous and waxy appearance as "resin opal"; if banded it is called "agate opal"; a green variety is termed "prase opal"; a dark red, ferruginous variety "jasper opal"; whilst "rose opal" is a beautiful pink mineral, coloured with organic matter, found at Quincys, near Mélun-sur-Yèvre, in France. A brown or grey concretionary opal from Tertiary shales near Milnontain, near Paris, is known as "macao." A dull opaque form of opal, with a fracture imperfectly conchoidal, is called "semi-opal," whilst the opal which infrequently forms the mineralizing substance of fossil wood passes as "wood opal." The name hydromele is applied to a porous opal, perhaps partially dehydrated, which is almost opaque when dry but becomes more or less transparent when immersed in water. It has been sometimes sold in America as "magic stone." Cacholong is another kind of porous opal with a lustre rather like that of mother-of-pearl, said to have been named from the Cach river in Bokhara, but the word is probably of Tatar origin.

Opaline silica is frequently deposited from hot siliceous springs, often in cauliflower-like masses, and is known as geyseric. This occurs at the springs of North Island New Zealand and the Yellowstone National Park. The form of the hot springs of Santa Fia, in Tuscany, is opaline silica, with a rather pearly lustre. A variety containing an exceptionally small proportion of water, obtained from the Yellowstone Park, was named pealite, after the chemist A. C. Pearce. The siliceous deposits from springs, often due to organic agencies, are known generally as "siliceous sinter" or, if very loose in texture, as "siliceous tuff." Opaline silica forms the material of many organic structures, like the frustules of diatoms and the tests of radiolarians which may accumulate as deposits of triolite, and be used for polishing purposes.

OPALINA (so named by J. E. Purkinjé and G. Valentin), a genus of Protozoa, without mouth or contractile vacuole, possessing nearly equal flagelliform cilia, and possessing numerous nuclei, all similar. It has been referred to Aspioricha by Bütschli, but by M. Hartog (Cambridge Natural History, vol. ii., 1906) has been transferred to the Flagellatae (q.v.). All the species are parasitic in cold-blooded Vertebrates.

See Bezenberger in Archiv. f. Protistenkunde (1903), iii. 138.

OPATA ("enemies," so called by their neighbours the Pimas), a tribe of Mexican Indians of Piman stock. Their country is the mountainous district of north-eastern Sonora and north-western Chihuahua, Mexico. Though usually loyal to the Mexican government, they rebelled in 1820, but after a gallant effort were defeated. They number now about 5000, and still largely retain their ancient autonomy.

OPERA (Italian for "work"), a drama set to music, as distinguished from plays in which music is merely incidental. Music has been a resource of the drama from the earliest times, and doubtless the results of researches in the early history of this connexion have been made very interesting, but they are hardly relevant to a history of opera as an art-form. If language has meaning, an art-form can hardly be said to exist under conditions where the only real connexions between its alleged origin and its modern maturity are such universal means of expression as can equally well connect it with almost everything else. We will therefore pass over the orthodox history of opera as traceable from the music of Greek tragedy to that of miracle-plays, and will begin with its real beginning, the first dramas that were set to music in order to be produced as musical works of art, at the beginning of the 17th century.

This original opera was represented by Doni, of the meetings held by a group of amateurs at the house of the Bardi in Florence in the last years of the 16th century, with the object of trying experiments in emotional musical expression by the use of instruments and solo voices. Before this time there was no real opportunity for music-drama. The only high musical art of the 16th century was unaccompanied choral music: its expression was perfect within its limits, and its limits so absolutely excluded all but what may be called static or contemplative emotion that "dramatic music" was as inconceivable as "dramatic architecture." But the literary and musical dilettanti who met at the house of the Bardi were not mature musical artists; they therefore had no scruples, and their imaginations were fired by the dream of restoring the glories of Greek tragedy, especially on the side of its musical declamation. The first pioneer in the new "monodic" movement seems to have been Vincenzo Galilei, the father of Galileo. This enthusiastic amateur warbled the story of Ugofiglio to the accompaniment of the flute, his manner of expressing expert musicians; but he grounded the respect and sympathy for the drama which was the first literary rather than musical. His efforts must have been not unlike a wild caricature of Mr. W. B. Yeats's method of reciting poetry to the psaltery. The first public production in the new style was Jacopo Peri's Euridice (1600), which was followed by a less successful effort of Caccini's on the same subject. To us it is astonishing that an art so great as the polyphony of the 17th century could ever have become forgotten in a new venture so feeble in its first steps. Sir Hubert Parry has happily characteterized the general effect of the new movement on contemporary imagination as something like that of laying a foundation-stone—the suggestion of a vista of possibilities so insipiring as to exclude all sense of the triviality of the present achievement. Meanwhile those composers who retained the mastery of polyphonic music tried to find a purely vocal and polyphonic solution of the problem of music-drama; and the Amfiparnasso of Orazio Vecchi (written in 1594, the year of Palestrina's death, and produced three years later) is not alone, though it is by far the most remarkable, among attempts to make a music-drama out of a series of musical numbers. From the first edition of the Amfiparnasso it has been conjectured that the actors sang one voice each, while the rest of the harmony was supplied by singers behind the stage; and this may have been the case with other works of this kind. But the words of Vecchi's introductory chorus contradict this idea, for they tell the audience that "the theatre of this drama is the world" and that the spectators must "hear instead of seeing."
OPERA

With the decadence of the madrigal, Monteverde brought a real musical power to bear on the new style. His results are not onlylegible only to historians, and they seem to us artistically nugatory; but in their day they were so impressive as to render the further continuance of 16th-century choral art impossible. At the beginning of the 17th century no young musician of lively artistic receptivity could fail to be profoundly stirred by Monteverde’s Orfeo (1602), Arianna (1608) and Il Combattimento di Tancredi e Clorinda (1624), works in which the resources of instruments were developed with the same archaic boldness, the same grasp of immediate emotional effect and the same lack of artistic organization as the harmonic resources. The spark of Monteverde’s genius produced in musical history a result more like an explosion than an enlightenment; and the emotional rhetoric of his art was so uncontrollable, and at the same time so much more impressive in suggestion than in realization, that we cannot be surprised that the next definite step in the history of opera took the direction of mere musical form, and was not only undramatic but anti-dramatic.

The system of free musical declamation known as recitative is said to have been used by Emilio del Cavallari as early as 1588, and it was in the nature of things almost the only means of vocal expression conceivable by the pioneers of opera. Formal melody, such as that of popular songs, was as much beneath their dignity as it had been beneath that of the high art from which they revolted; but, in the absence of any harmonic system but that of the church modes, which was manifestly incapable of assimilating the new “unprepared discords,” and in the utter chaos of early experiments in instrumentation, formal melody proved a godsend as the novelty of recitative faded. Tunes were soon legalized at moments of dramatic repose when it was possible for the actors to indulge in either a dance or a display of vocalization; it was in the tunes that the strong harmonic system of modern tonality took shape; and by the early days of Alessandro Scarlatti, before the end of the 18th century, the art of tune-making had been intrinsically tied up into the musically safe and effective form of the aria (q.v.).

From this time until the death of Handel the history of opera is simply the history of the aria; except in so far as in France, under Lully, it is also the history of ballet-music, the other main theatrical occassion for the art of tune-making. With opera before Gluck there is little interest in tracing schools and developments, for the musical art had as mechanical a connexion with drama as it had with the art of scene-painting, and neither it nor the drama which was attached to it showed any real development at all, though the librettist Metastasio presented as imposing a figure in 18th-century Italian literature as Handel presented in Italian opera. Before this period of stagnation we find an almost solitary and provincial outburst of life in the wonderful patchwork of Purcell’s art (1659-1695). Whether he is producing genuine opera (as in the unique case of Dido and Aeneas) or merely incidental music to plays (as in the so-called opera King Arthur), his deeply inspired essays in dramatic music are no less interesting in their historic isolation from everything except the influence of Lully than they are admirable as evidence of a genius which, with the opportunities of 50 years later or 150 years earlier, might assuredly have proved one of the greatest in all music. Another sign of life has been appreciated by recent research in the interesting farcical operas (mostly Neapolitan) of certain early 18th-century Italian composers (see Leo, Pergelese, Logroscino), which have some bearing on the antecedents of Mozart.

The real reason for the stagnation of high opera before Gluck is (as explained in the articles Music and Sonata Forms) that the forms of music known before 1750 could not express dramatic change without losing artistic organization. The “spirit of the age” can have had little to do with the difficulty, or why should Shaftesbury and Locke have had a contemporary operatic brother-artist during the “Golden Age” of music? The opportunity for reform came with the rise of the sonata style.

It was fortunate for Gluck that the music of his time was too vigorously organized to be upset by new discoveries. Gluck was

a much greater artist than Monteverde, but he too was not overladen with academic mastery; indeed, though historians have denied it, Monteverde was by far the better contrapuntist, and seems rather to have renounced his musical powers than to have struggled for need of them. But instead of memories of a Golden Age, Gluck had behind him 150 years of harmonic and orchestral knowledge of good and evil. He also had almost as clear a sense of symphonic form as could find scope in opera at all; and his melodic power was generally of the highest order.

It is often said that his work was too far in advance of his time to establish his intended reform; and, if this means that undramatic Italian operas continued to outnumber those dramatic masterpieces which no smaller man could achieve, the statement is as true as it is of every great artist. If, however, it is taken to mean that because Mozart’s triumphs do not lie in serious opera he owes nothing to Gluck, then the statement is misleading (see Gluck). The influence of Gluck on Mozart was profound, not only where it is relevant to the particular type of libretto, as in Idomeneo, but also on the broad dramatic basis which includes Greek tragedy and the 18th-century comedy of manners.

Mozart, whose first impulse was always to make his music coherent in itself, for some time continued to cultivate side by side with his growing polyphony and freedom of movement certain Italian formalities which, though musically effective and flattering to singers, were dramatically vicious. But these features, though they spoil Idomeneo, correspond to much that in Gluck’s operas shows mere helplessness; and in comic opera they may even become dramatically appropriate. Thus in Così fan tutte the florid arias in which the two heroines protest their fidelity are the arias of ladies who do protest too much; and in Die Zauberflöte the extravagant vocal fireworks of the Queen of Night are the displays of one who, in the words of the high priest Sarastro, “hopes to cajole the people with illusions and superstition.”

In the article MOZART we have discussed other evidences of his stagecraft and insight into character, talents for which his comic work is more characteristic of him than the stylized effects he had given to Gluck. Mozart always extracts the utmost musical effect from every situation in his absurd and often tiresome librettis (especially in vocal ensemble), while his musical effects are always such as give dramatic life to what in other hands are conventional musical forms. These merits would never have been gainsaid but for the violence of Wagner’s earlier partisans in their revolt from the uncritical classicism of his denser and noisier opponents. Wagner himself stands as far aloof from Wagnerian Philistinism as from uncritical classicism. He was a fierce critic of social conditions and by no means incapable of hasty iconoclastic judgments; but he would have treated with scant respect the criticism that censures Mozart for superficiality in rejecting the radically unmusical element of mordant social satire which distinguishes the Figaro of Beaumarchais from the most perfect opera in all classical music.

It cannot be said that in any high artistic sense Italian comic opera has developed continuously since Mozart. The vocal athleticism of singers; the acceptance and great development by Mozart of what we may call symphonic (as distinguished from Handelian) forms of aria and ensemble; and the enlargement of the orchestra; these processes gave the Italian composers of Mozart’s and later times prosaically golden opportunities for lifting spectators and singers to the seventh heaven of flattered vanity, while the music, in itself no less than in its relation to the drama, was steadily degraded. The decline begins with Mozart’s contemporary and survivor, D. Cimarosa, whose ideas are genuine and, in the main, refined, but who lacks power and resource. His style was by no means debased, but it was just so slight that contemporaries found it fairly easy. His most famous work, Il Matrimonio Segreto, is an opera buffa which is still occasionally revived, and it is very like the sort of thing that people who despise Mozart imagine Figaro to be. Unless it is approached with sympathy, its effect after Figaro is hardly more exhilarating than that of the once pilloried spurious “Second Part” to the Pickwick Papers.

But this is harsh judgment; for it proves to be a good semi-classic as soon as we take it on its own merits.
It is far more musical, if less vivacious, than Rossini's *Barberia*; and the decline of Italian opera is more significantly foreshadowed in Cimarosa's other chef-d'oeuvre, the remarkable opera seria, *Gli Orazi ed i Curiazi*. Here the arias and ensembles are serious art, showing a pale reflection of Mozart, and not wholly without Mozart's spirit, the choruses, notably the first of all, have fine moments; and the treatment of conflicting emotions at one crisis, where military music is heard behind the scenes, is masterly. Lastly, the abrupt conclusion at the moment of the catastrophe is good and was novel at the time, though it foreshadows that sacrifice of true dramatic and musical breadth to the desire for an "effective curtain," and that mortal fear of anti-climax which in classical French opera rendered a great musical finale almost impossible. But the interesting and dramatic features in *Gli Orazi* are unfortunately less significant historically than the vulgarity of its overture, and the impossibility, after the beautiful opening chorus, of tracing any unmistakably tragic style in the whole work except by the negative sign of dulness.

Before Cimarosa's overwhelming successor Rossini had retired from his indolent career, these tendencies had already reduced both composers and spectators to a supreme indifference to the mood of the libretto, an indifference far more fatal than mere inattention to the plot. Nobody cares to follow the plot of Mozart's *Figaro*; but then no spectator of Beaumarchais's *Mariage de Figaro* is prevented by the intricacy of its plot from enjoying it as a play. In both cases we are interested in the character-drawing and in each situation as it arises; and we do no justice to Mozart's music when we forget this interest, even in cases where the libretto has none of the literary merit that survives in the transformation of Beaumarchais's comedy into an Italian libretto. But with the Rossinian decline all charitable scruples of criticism are misplaced, for Italian opera once more became as purely a pantomimic concert as in the Handelian period; and we must not ignore the difference that it was now a concert of very vulgar music, the work of which, at the growing range and interest of dramatic subjects, the best that can be said in defence of it was that the vulgarity was not pretentious and unhealthy, like Meyerbeer's; indeed, if the famous "Mad Scene" in Donizetti's *Lucia di Lammermoor* had only been meant to be funny it would not have been vulgar at all. Occasionally the drama pierced through the empty breeness of the music; and so the spirit of Shakespeare, even when smothered in an Italian libretto unsuccessfully set to music by Rossini, proved so powerful that one spectator of Rossini's *Otello* is recorded to have started out of his seat at the catastrophe, exclaiming "Good Heavens! the tenor is murdering the soprano!" And in times of political unrest more than one opera became as dangerous as an over-censored theatre could make it. An historical case in point is brilliantly described in George Meredith's *Vittoria*. But what has this to do with the progress of music? The history of Italian opera from its culmination in Mozart to its subsidence on the big drum and cymbals of the Rossinians is the history of a protected art. Verdi's art, both in its burly youth and in its shrewd old age, is far more the crown of his native genius than of his native traditions; and, though opinions differ as to the spontaneity and depth of the change, the paradox is true that the Wagnerization of Verdi was the musical emancipation of Italy.

After Mozart the next step in the development of true operatic art was neither Italian nor German, but French. The French sense of dramatic fitness had a wonderfully stimulating effect upon every foreign composer who came to France. Rossini himself, in *Guillaume Tell*, was electrified into a dramatic and orchestral life of an incomparably higher order than the rollicking rattle of serious and comic Italian opera in its decline. He was in the prime of life when he wrote it, but it exhausted him and was his last important work, though he lived to a cheerful old age. The defects of its libretto were grave, but he made unprecedented efforts to remedy them, and finally succeeded, at the cost of an entire act. The experience was very significant; for, from the time of Gluck onwards, while it cannot be denied that native and naturalized French operatic art has suffered from many forms of musical and dramatic debasement, we may safely say that no opera has hitherto with success in France that is without theatrical merit. And the French contribution to musical history between Gluck and Rossini is of great nobility. If Cherubini and Mélhul had had Gluck's melodic power, the classics of French opera would have been the greatest achievements in semi-tragic music-drama before Wagner. As it is, their austerity is not that of the highest classics. It is negative, and tends to exclude outward attractiveness rather than that it cannot achieve it than because it contains all things in due proportion. Be this as it may, Cherubini had a real influence on Beethoven; not to mention that the libretti of Fidelio and *Les Deux Journées* were originally by the same author, though Fidelio underwent great changes in translation and revision. It is impossible to say what French opera might have done for music through Beethoven if *Fidelio* had not continued his solitary (because very nearly unsuccessful) operatic monument; but there is no doubt as to its effect on Weber, whose two greatest works, *Der Freischütz* and *Euryanthe*, are two giant strides from Cherubini to Wagner. *Euryanthe* is in respect of *Leit-motif* (see below) almost more Wagnerian than *Lohengrin*, Wagner's fourth published opera. It failed to make an epoch in history because of its dreary libretto, to which, however, the highly dramatic libretto of *Lohengrin* owes a surprising number of points.

The libretti of classical opera set too low a literary standard to induce critics to give sufficient attention to their aesthetic bearings; and perhaps the great scholar Otto Jahn is the only writer who has applied a first-rate literary analysis to the subject (see his *Life of Mozart*); a subject which, though of great importance to music, has, like the music itself, been generally thrust into the background by the countless externals that give theatrical works and institutions a national or political importance, the monopoly of which, of course, is of the utmost importance to the architectonic and historical development. Much that finds prominent place in the opera is really outside the scope of musical and dramatic discussion; and it may therefore be safely left to be discovered under non-musical headings elsewhere in this Encyclopaedia. Even when what passes for operatic history has a more real connexion with the art than the history of locomotion has with physical science, the importance of the connexion is often overrated. For example, much has been said as to the progress in German opera from the choice of remote subjects like Mozart's *The Entführung aus dem Serail* to the choice of a subject so thoroughly German as *Der Freischütz*: but this is only one part of the general progress made, chiefly in France, towards the choice of Roman instead of classical subjects. Whatever the intrinsic interest of musical technology, and whatever light it may throw upon the reasons why an art will develop and decline sooner in one country than in another, racial character will not suffice to produce an art for which such a technique as yet exists. Nor will it suffice in any country to check the development or destroy the value of an art of which the principles were developed elsewhere. No music of Mozart's time could have handled Weber's romantic subjects, and all the Teutonism in history could not have prevented Mozart from adopting and developing those Italian methods that gave him scope. Again, in the time of Lully, who was the contemporary of Molière, the French genius of stagecraft was devoted to reducing opera to an effective series of ballets; yet so little did this hamper composers of real dramatic power that Quinault's libretto to Lully's very successful *Armide* served Gluck unaltered for one of his greatest works 90 years later. If Lully owes so little to Cambert as to be rightly entitled the founder of French opera, if Gluck is a greater reformer than his predecessor Rameau, if Cherubini is a more powerful artist than Mélhul, and if, lastly, Meyerbeer developed the vices of the French historicism in Germany with a plausibility which has never been surpassed, then we must reconcile our racial theories with the historic process by which the French *Grand Opéra*, one of the most pronounced national types in all music, was founded by an Italian Jew, reformed by an Austrian.
OPERA

classicized by another Italian, and debased by a German Jew. This only enhances the significance of that French dramatic sense which stimulated foreign composers and widened their choice of subjects, as it also preserved all except the Italian forms of opera from falling into that elsewhere prevalent early 19th-century operatic style in which there was no means of guessing by the music whether any situation was tragic or comic. From the time of Meyerbeer onwards, trivial and vulgar opera has been as common in France as elsewhere; but there is a world of difference between, for example, a garish tune naively intended for a funeral march, and a similar tune used in a serious situation with a dramatic sense of its association with other incidents in the opera, and of its contrast with the sympathies of spectator and actors. The first case is as typical of 19th-century musical Italy as the second case is of musical France and all that has come under French influence.

As Wagner slowly and painfully attained his maturity he learned to abhor the influence of Meyerbeer, and indeed it accounts for much of the inequality of his earlier work. But it can hardly have failed to stimulate his sense of effect; and without the help of Meyerbeer's outwardly successful novelties it is doubtful if Wagner could have faced the task of his early work, a task so negative and destructive in its first stages. We have elsewhere (see Music, Sonata Forms ad finem, and Symphonic Poem) described how if music of any kind, instrumental or dramatic, was to advance beyond the range of the classical symphony, there was need to devise a kind of musical motion and proportion as different from that of the sonata or symphony as the sonata style is different from that of the suite. All the vexed questions of the function of vocal ensemble, of the structure of the libretto, and of instrumentation, are but aspects and results of this change in what is in much a primary category of music as extension is a primary category of matter. Wagnerian opera, a generation after Wagner's death, was still an unique phenomenon, the rational influence of which was not yet sifted from the concomitant confusions of thought prevalent among many composers of symphony, oratorio, and other forms of which Wagner's principles can be relevant only with incalculable modifications. With Wagner the history of classical operas ends and a new history begins, for in his hands the first became a single and indivisible music-drama, instead of a kind of dramatic casket for a collection of objets d'art more or less aptly arranged in theatrical tableaux.

Forms and Terminology of Opera.

The history of pre-Wagnerian opera is not, like that of the sonata forms, a history in which the technical terminology has a clear relationship to the aesthetic development. In order to understand the progress of classical opera we must understand the whole progress of classical music; and this not merely for the general reason that the development of an art-form is inseparable from the development of the whole art, but because in the case of opera only the most external terminology and the most unreal and incoherent history of fashions and factions remain for consideration after the general development of musical art has been discussed. For completeness, however, the terminology must be included; and a commentary on it will complete our sketch in better historical perspective than any attempt to amplify this history of a continuous history.

1. Recitative is the delivery of ordinary operatic dialogue in monosyllactic recitative-formulas, accompanied by nothing but a harpsichord or pianoforte. In comic operas it was not so bad a method as some critics imagine; for the conductor (who sat at the harpsichord or pianoforte) would, if he had the wits expected of him by the composer, extemporize his accompaniments in an unobtrusively amusing manner, while the actors delivered their recitative rapidly in a conversational style known as parlante. In serious operas, however, the conductor dare not be frivolous; and accordingly secco-recitative outside comic opera is the drearlest of make-shifts, and is not tolerated by Gluck in his mature works. He accompanies his recitatives with the string band, introducing other instruments freely as the situation suggests.

2. Accompanied recitative was used in all kinds of opera, as introductory to important arias and other movements, and also in the course of finales. Magnificent examples abound in Idomeneo, Figaro and Don Giovanni; and one of the longest recitatives before Wagner is that near the beginning of the finale of the first act of Die Zauberflote. Beethoven's two examples in Fidelio are short but of overwhelming pathos.

3. Melodrama is the use of an orchestral accompaniment to spoken dialogue (see BENDA). It is wonderfully promising in theory, but generally disappointing in effect, unless the actors are successfully trained to speak without being dragged by the music into an out-of-tune sing-song. Classical examples are generally short and cautious, but very impressive; there is one in Fidelio in which the orchestra quotes two points from earlier movements in a thoroughly Wagnerian way (see Leitmotiv below). But the device is more prominent in incidental music to plays, as in Beethoven's music for Goethe's Eigmont. Mendelssohn's music for A Midsummer Night's Dream contains the most brilliant and resourceful example yet achieved in this art; but it is an experiment beyond the musical capacity of the English stage, which, however, has practised the worst forms of the method until it has become a disease, many modern performances of Shakespeare attaining an almost operatic continuity of bad music.

4. Opera buffa is classical Italian comic opera with secco-recitative. Its central classics are, of course, Figaro and Don Giovanni, while Cimarosa's Matrimonio Segreto and Rossini's Barbiere are the most important steps from the culmination to the fall.

5. Opera seria is classical Italian opera with secco-recitative; almost always (like the Handelian opera from which it is derived) on a Greek or Roman subject, and, at whatever cost to dramatic or historic propriety, with a happy ending. Gluck purposely avoids the term in his mature works. The only great classic in opera seria is Mozart's Idomeneo, and even that is dramatically too unequal to be more than occasionally revived, though it contains much of Mozart's finest music.

6. The Singspiel is German opera with spoken dialogue. In early stages it advanced from the farcical to the comic. With Beethoven it came under French influence and adopted "thrilling" stories with happy endings; and from this stage it passed to specifically "Romantisch" subjects. Its greatest classics are Mozart's Entführung and Zauberflöte, Beethoven's Fidelio, and Weber's Freischütz.

7. Opéra comique is the Singspiel of France, being French opera with spoken dialogue. It did not originate in farce but in the refusal of the Académie de Musique to allow rival companies to infringe its monopoly of Grand Opéra; and it is so far from being essentially comic that one of its most famous classics, Méhul's Joseph, is on a Biblical subject; while its highest achievement, Cherubini's Les Deux journées, is on a story almost as serious as that of Fidelio. All Cherubini's mature operas (except the ballet Anaxirion, which is uninterrupted music from beginning to end) are opéras comiques in the sense of having spoken dialogue; though Médée, being, perhaps, the first grand tragedy in the history of music-drama,1 is simply called "opéra" on the title-page. In the smaller French works, especially those in one act, there is so much spoken dialogue that they are almost like plays with incidental music. But they never sink to the condition of the so-called operas of the English composers since Handel. When Weber accepted the commission to write Oberon for the English stage in 1825, he found that he was compelled to set the musical numbers one by one as they were sent to him, without the slightest information as to the plot, the situation, or even the order of the pieces! And, to crown his disgust, he found that this really did not matter.

1 Even Gluck never contemplated any alternative to the absurd happy ending of Orfeo; and all his other operatic subjects include a den ex machina.
to that ingenious compromise which classical opera made between music that completed from 12 to 30 independent designs and the drama that meanwhile completed one. But when the music became as continuous as the drama, the case was different. There are plenty of classical instances of a theme superficially marking some cardinal incident or personal characteristic, without affecting the independence of the musical forms; the commonest case being, of course, the allusion somewhere in the overture to salient points in the body of the opera; as, for instance, the allusion to the words "così fan tutte" in the overture to Mozart's opera of that name, and the Masonic threefold chord in that to the Zauberflöte. Weber's overtures are sonata-form fantasias on themes to come: and in later and lighter operas such allusiveness, being childishly easy, is a meaningless matter of course. Within the opera itself, songs, such as would be sung in an ordinary non-musical play, will probably recur, as in Le Deux journées; and so will all phrases that have the character of a call or a signal, a remarkable and pathetic instance of which may be found in Mélusin's Méléidore et Phrösine, where the orchestra makes a true Leit-motif of the music of the heroine's name. But it is a long way from this to the system already clearly marked by Weber in Die Freischiitz and developed in Euryanthe, which shows how Wagner did not surpass in any earlier work than Tristan, though in respect of the obliteration of sections his earliest works are in advance of Weber. Yet not only are there some thirteen recurring musical incidents in the Freischiitz and over twenty in Euryanthe, but in the latter the serpentine theme associated with the treacherous Eglantine actually stands the Wagnerian test of being recognizable when its character is transformed. This can hardly be claimed even for the organization of themes in Lohengrin.

Mature Wagnerian Leit-motif is a very different thing from the crude system of musical labels to which some of Wagner's disciples have reduced it, and Wagner himself had no patience with the catalogue methods of modern operatic analysis. The Leit-motif system of Tristan, the Meistersinger, the Ring and Parsifal is a profoundly natural and subtle cross-current of musical thought, often sharply contrasted with the externals of a dramatic situation, since it is free to reflect not only these externals, not only the things which the audience know and the dramatic course and the action as it is proceeding, but those workings of the dramatic character's mind which he is trying to conceal from the other characters, but even those which he conscious of himself. There was nothing new in any one of these possibilities taken singly (see, for example, Gluck's ironic treatment of "le calme rentre dans mon cœur"), but polyphonic Leit-motif made them all possible simultaneously. Wagner's mind was not concentrated on the merely literary and theatrical aspects of music-drama; he fought his way to the topmost heights of the peculiar musical mastery necessary to his ideals; and so he realized that principle in which none but the very greatest musicians find freedom; the principle that, however constantly necessary and powerful homophonic music may be in passages of artificial simplicity, all harmonic music is by nature and origin polyphonic; and that in polyphony lies the normal and natural means of expressing a dramatic blending of emotions.

Wagnerian Leit-motif has proved rather a giant's robe for later composers; and the most successful of recent operas have, while aiming less at the sublime, cultivated Wagner's musical and dramatic continuity more than this principle of musical texture. Certainly Wagnerian continuity is a permanent postulate in modern opera; but it shows itself to be a thing attainable quite independently of any purely musical style or merit, so long as the dramatic movement of the play is good. This condition was always necessary, even where opera was most symphoniet. Mozart was incessantly disputing with his librettists; and all his criticisms and changes, though apparently of purely musical purport, had a brilliant effect on the movement of the play. In one desperate case, where the librettist was obstinate, Mozart abandoned a work (L'oca del Cairo) to the first act of which he had already sketched a great finale embodying a grandiose farcical figure that promised to be unique in classical opera.
Mozart’s lesson of dramatic movement has been better learnt than anything peculiar to either music or literature; for, while his librettists show how little that quality has to do with poetic meaning, the masters of Italian opera from Rossini to Mascaroni shows how little it has to do with good music. On the other hand, the musical coherence of the individual classical forms used in opera has caused many critics to miss the real dramatic ground of some of the most important operatic conventions. The chief instance of this is the repetition of words in arias and at climaxes, a convention which we are over-ready to explain as a device which prolongs situations and delays action for the sake of musical design. But in the best classical examples the case is almost the reverse, for the aria does not, as we are apt to suppose, represent a few words repeated so as to serve for a long piece of music. Without the music the drama would have required a long speech in its place; but the classical composer cannot fit intelligible music to a long string of different sentences, and so the librettist reduces the speech to mere headlines and the composer supplies the elocution. Herein lies the meaning of Mozart’s rapid progress from vocal concertos like “Fuor del mar” in Idomeneo and “Martern aller Arten” in Die Entführung to genuine musical speeches like “Non piu andrai” in Figaro, in which the obvious capacity to deal with a greater number of words is far less important than the naturalness and freedom with which the pace of the declamation is varied—a freedom unsurpassed even in the Elektra of Richard Strauss.

With Wagnerian polyphony and continuity music became capable of treating words as they occur in ordinary speech, and repetitions have accordingly become out of place except where they would be natural without music. But it is not here that the real gain in freedom of movement lies. That gain has been won, not by Wagner’s negative reforms alone, but by his combination of negative reform with new depths of musical thought; and modern opera is not more exempt than classical opera from the dangers of artistic methods that have become facile and secure. If the libretto has the right dramatic movement, the modern composer need have no care beyond what is wanted to avoid interference with that movement. So long as the music arouses no obviously incompatible emotion and has no breach of continuity, it may find perfect safety in being meaningless. The necessary stagecraft is indeed not common, but neither is it musical. Critics and public will cheerfully agree in ascribing to the composer all the qualities of the dramatist; and three allusions in the music of one scene to that of another will suffice to pass for a marvellous development of Wagnerian Leit-motif.

Modern opera of genuine artistic significance ranges from the light song-play type admirably represented by Bizet’s Carmen to the exclusively “atmospheric” impressionism of Debussy’s Pelléas et Mélisande. Both these extremes are equally natural in effect, though diametrically opposite in method; for each tries to eliminate everything that would be inadmissible in ordinary drama. If we examine the libretto of Carmen as an ordinary play we shall find it to consist mainly of actual songs and dances, so that more than half of the music would be necessary even if it were not an opera at all. Debussy’s opera differs from Maeterlinck’s play only in a few omissions such as would probably be made in ordinary non-musical performances. His musical method combines perfect Wagnerian continuity with so entire an absence of Leit-motif that there are hardly three musical phrases in the whole opera that could be recognized if they recurred in fresh contexts. The highest conceivable development of Wagnerian continuity has been attained by Strauss in Salome and Elektra; these operas being actually more perfect in dramatic movement than the original plays of Wilde and Hofmannsthal. But their use of Leit-motif, though obvious and impressive, is far less developed than in Wagner; and the polyphony, as distinguished from the brilliant instrumental technique, is, like that technique, devoted mainly to realistic and physically exciting effects that crown the impression in much the same way as skilful lighting of the stage. Certainly Strauss does not in his whole time-limit of an hour and three-quarters use as many definite themes (even in the shortest of figures) as Wagner uses in ten minutes.

It remains to be seen whether a further development of Wagnerian opera, in the sense of addition to Wagner’s resources in musical architecture, is possible. The uncompromising realism of Strauss does not at first sight seem encouraging in this direction; yet his treatment of Elektra’s first invocation of Agamemnon produces a powerful effect of musical form, dimly perceived, but on a larger scale than even the huge sequences of Wagner. In any case, the best thing that can happen in a period of musical transition is that the leading revolutionaries should make a mark in opera. Musical revolutions are too easy to mean much by themselves; there is no purely musical means of testing the sanity of the revolutionaries or of the critics. But the stage, while boundlessly tolerant of bad music, will stand no nonsense in dramatic movement. (The case of Handelian opera is no exception, for in it the stage was a mere topographical term.) In every period of musical fermentation the art of opera has instantly sifted the men of real ideas from the aesthetes and doctrinaires; Monteverde from the prince of Venosa, Gluck from Gosses, and Wagner from Liszt. As the ferment subsides, opera tends to a complacent decadence; but it will always revive to put to the first and most crucial test every revolutionary principle that enters into music to destroy and expand.

We also have: ARIA; CHERUBINI; GLUCK; MOZART; VERDI; WAGNER; WEBER.

(Ed. F. T.)

**OPHICLEIDE** (Fr. ophicleide, base d’harmonie; Ger. Ophiklaid; Ital. ophicleide), a brass wind instrument having a cup-shaped mouthpiece and keys, in fact a bass keyed-bugle. The name (from Gr. ὁφίσα, serpent, and κλῆθές, keys), applied to it by Halary, the patentee of the instrument, is hardly a happy one, for there is nothing of the serpent about the ophicleide, which has the bore of the bugle and also owes the chromatic arrangement of the keys to a principle evolved by Halliday for the bugle, to be explained later on.

The ophicleide is almost perfect theoretically, for it combines the natural harmonic scale of the brass wind instruments having cup-shaped mouthpieces, such as the trumpet, with a system of keys, twelve in number, one for each chromatic semitone of the scale; it is capable of absolutely accurate intonation. It consists of a wooden, or often brass, tube with a conical bore having the same proportions as that of the bugle but not wide enough in proportion to its length to make the fundamental or first note of the harmonic series of much practical use. The tube, theoretically 5 ft. long, is doubled upon itself once, terminating at the narrow end in a tight coil, from which protrudes the straight piece known as the crook, which bears the cup-shaped mouthpiece; the wide end of the tube terminates in a funnel-shaped bell pointing upwards.

The production of sound is effected in the ophicleide as in other instruments with cup- or funnel-shaped mouthpieces (see HORN). The lips stretched across the mouthpiece act as vibrating reeds or as the vocal chords in the larynx. The breath of the performer, compressed by being forced through the narrow opening between the lips, sets the latter in vibration. The stream of air, instead of proceeding into the cup in an even flow—in which case there would be no sound—is converted into a series of pulsations by the trembling of the lips. On being thrown into communication with the main stationary column of air at the bottom of the cup, the pulsating stream generates “sound waves,” each consisting of a half wave of expansion and of a half wave of compression. On the frequency per second of the sound waves as they strike the drum of the ear depends the pitch of the note, the acuteness of the sound varying in direct proportion to the frequency. To ensure a higher frequency in the sound waves, their length must be decreased. Two things are necessary to bring this about without shortening the length of the tube: (1) the opening between the lips, fixed at each end by contact with the edges of

For an explanation of the difference between theory and practice in the length of the tubes of wind instruments, see Victor Mahillon, "Le cor" (Les instruments de musique au musée du conservatoire royal de musique de Bruxelles, pt. ii, Brussels and London, 1907), pp. 27-29.
the mouthpiece, must be made narrower by greater tension; (2) the breath must be sent through the reduced aperture in a more compressed form and with greater force, so that the exciting current of air becomes more incisive. An exact proportion, not yet scientifically determined, evidently exists between the amount of pressure and the degree of tension, which is unconsciously regulated by the performer, excess of pressure in proportion to the tension of the lips producing a crescendo by causing amplitude of vibration instead of increased speed.

When the fundamental note of a pipe is produced, the tension of the lips and pressure of breath proportionally combined are at their minimum for that instrument. If both be doubled, a node is formed half way up the pipe, and the column of air no longer vibrates as a whole, but as two separate parts, each half the length of the tube, and the frequency of the sound waves is doubled in consequence. The practical result is the production of the second of which is the series an octave above the fundamental. The formation of these nodes and therefore of three separate sound waves produces a note a twelfth above the fundamental, known as the third harmonic, and so on in mathematical ratio. This harmonic series forms the natural scale of the instrument, and is for the ophicleide the following:

\[
\begin{array}{c|c|c|c|c|c|c|c|c|c|c|c|c}
 & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & \text{Fundamental} \\
\hline
5 & 6 & 7 & 8 & 9 & 10 & 11 & 1 & 2 & 3 & 4 & 5 & 6
\end{array}
\]

In some cases the fundamental is difficult to obtain, and the harmonics above the eighth are not used.

The ophicleide has in addition to its natural scale eleven or twelve accidental notes, which can be produced by keys, each of which, when successively opened, raises the pitch of the harmonic series a semitone, with the exception of the first, an open key, which on being closed lowers the pitch a semitone. There were ophicleides in C and in B♭, the former being the more common; contrabass ophicleides were also occasionally made in F and E♭. The keys of the ophicleide, being placed in the lowest register, were intended to bend together by chromatic degrees the first and second harmonics. The compass is a little over three octaves, from G₂ to G⁶ with chromatic semitones throughout.

The unsatisfactory timbre of the ophicleide led to its being superseded by the bass tuba; but it seems a pity that an instrument so powerful, so easy to learn and understand, and capable of such accurate intonation, should have to be discarded. The lower register is, however, so powerful that it can easily sustain above it masses of brass harmonies; the medium is coarse in tone, and the upper wild and unmusical.

Although a bass keyed-bugle, the ophicleide owes something of its origin to the application of keys to the serpent (q.v.), a wind instrument familiarly known in the 16th century under various names, by Guillaume, canon of Auxerre, about 1590. The serpent remained in its primitive form for nearly two centuries, and then only was it attempted to improve by adding keys. It was a musician named Régibo, born in Paris, who was the first to give the shape of a bassoon. The merit of this innovation was quickly recognized in England and Germany. Still, to follow Gerber, one Frichot, who was a maker of instruments, and who was established in Lille, who, about 1750, first thought of giving it the shape of a bassoon. The ophicleide, or bass tuba, as the instrument was called by the common people, was first manufactured by the company of designers which worked under the name of Frichot, from 1784 to 1817, when it was taken over by the company of Halliday, who still makes a large proportion of the ophicleides sold in the United States.

The ophicleide is generally believed to have been invented by Alexandre Frichot, a professor of music at Liévin, department of Pas-de-Calais, France. The instrument, which the inventor called "basse-trompette," was approved of as early as 13th November 1806 by a commission composed of professors of the Paris Conservatoire, but the patent bears the date 31st December 1810. This instrument was called "base-trompette," which Frichot in his specifications had at first, in imitation of the English bass horn, called "base cor," was, like the English instrument, entirely of brass, and had, like it, six holes; it was adopted in a modified form by the brass band leaders on the Continent, and was extensively used by the English navy; but it was not adopted in the army until 1806, when it was introduced into the band at the French army camp. The first ophicleides were divided into two sections, each with its own valve box, and the valve box was connected by a long tapering tube. The valves were made of metal, and the ophicleide was made of brass. The ophicleide was made in C and in B♭, the contra-bass in F and E♭.

The announcement of Weldinger's invention of a Klappen- trompette, or trumpet with keys, appears in the Allg. musik. Ztg. (Leipzig, November 1802), p. 158; and further accounts are given in January 1803, p. 245, and 1815, p. 844.

The report of the Academy of Beaux-Arts on the subject of this invention shows a strange misconception of it, which it is interesting to recall. As to the two instruments which M. Halary designs
OPHİR—OPHTHALMOLOGY

It is certain that from the point of view of invention Halâry's labours had only secondary importance; but, if the principle of keyed chromatic instruments with cupped mouthpiece goes back to Halâry, it was Halâry's merit to know how to take advantage of the principle of extending it to different families, and to do so in grouping them in one single family, that of the bugles, in so complete a manner that the improvements of modern manufacture have not widened its limits either in the grave or the acute direction. Keyed chromatic wind-instruments, such as the cornet or the trumpet, have been introduced into military full or brass bands we can date the regeneration of military music. After pistons had been invented some forty years, instruments with keys could still reckon their partisans. Now these have largely disappeared, and pistons or rotary remains absolute masters of the situation.

(V. M.; K. S.)

OPHİR, a region celebrated in antiquity for its gold, which was proverbially fine (Job xxii. 24, xxvii. 16; Psalms lxi. 9; Isa. xxxii. 12). Thence Solomon's Phœnician sailors brought gold for their master (1 Kings ix. 28, xlvi. 1; 2 Chron. viii. 12, 20); Ophir gold was stored up among the materials for the Temple (1 Chron. xxvii. 4). Jehoshaphat, attempting to follow his ancestors' example, was foiled by the shipwreck of his navy (1 Kings xxii. 48). The situation of the place has been the subject of much controversy. The only indications whereby it can be identified are its connexion, in the geographical table (Gen. x. 29), with Sheba and Havilah, the latter also an auraliferous country (Gen. ii. 11), and the fact that ships sailing thither started from Ezion-geber at the head of the Red Sea. It must, therefore, have been somewhere south or east of Suez; and must be known to be a gold-bearing region. The suggested identification with the Egyptian Punt is in itself disputable, and it would be more helpful if we knew exactly where Punt was (see EGYP).

(1) East Africa.—This has, perhaps, been the favourite theory in recent years, and it has been backed up popularized by the seasoned chronologists Bent and others, to say nothing of one of Rider Haggard's novels. The centre of speculation is a group of extensive ruins at Zimbabwe, in Mashonaland, about 200 m. inland from Sofala. Many and wild words have been written on these imposing remains. But the results of the saner researches of MacDonald Maciver, announced first at the South Africa meeting of the British Association (1895) and later communicated to the Royal Geographical Society, have robbed these structures of much of their glamour; from being the centres of Phœnician and Hebrew industry they have sunk to be mere magnified kraals, not more than three or four hundred years old.

(2) The Far East.—Various writers, following Josephus and the Greek version, have placed Ophir in different parts of the Far East. A chief argument in favour of this view is the length of the voyages of Solomon's vessels (three years were occupied in the double voyage, going and returning, 1 Kings x. 22, 10); the nature of the other imports that they brought—"almug-trees" (i.e. probably sandal-wood), ivory, apes and peacocks. This, however, proves nothing. It is nowhere said that these various imports all came from one place; and the voyages must have been somewhat analogous to those of modern "coasting tramps," which would necessarily consume a considerable time over comparatively short journeys. It has been sought at the under the names of 'quinti-clave' and ophiste, they bear a great resemblance to those admitted to the Academy in the sitting of the 11th of March 1811 by M. Dumas, which he designed under the names of 'base et contrebase guerrières.' The opinion of our commission on the quinti-clave and ophiste is that M. Halâry can only be credited the merit of an improvement and not that of an entire invention; still, for an equitable judgment on this point, we should compare the one with the other, and this our commission cannot do, not having the instruments of M. Dumas at our disposal. Thence the instruments presented by M. Dumas were bass clarinet (Musicien Universel of 19th April 1811). We designedly omit the word 'brass' to qualify these instruments. The substance which determines the form of a column of air is demonstrably indifferent for the timbre or quality of tone so long as the sides of the tubes are equally elastic and rigid.

Abhira, at the mouth of the Indus (where, however, there is no gold); at Supara, in Goa; and at a certain Mount Ophir in Johore.

(3) Arabia.—On the whole the most satisfactory theory is that Ophir was in some part of Arabia—whether south or east is disputed, and (with the indications at our disposal) probably cannot be settled. Arabia was known as a gold-producing country to the Phœnicians (Ezek. xxvii. 22); Sheba certainly, and Havilah probably, are regions of Arabia, and these are coupled with Ophir in Genesis x.; and the account of the arrival of the navy in 1 Kings x. 11, is strangely interwoven into the story of the visit of the queen of Sheba, perhaps because there is a closer connexion between the two events than appears at first sight.

Historians have been at a loss to know what Solomon could give in exchange for the gold of Ophir and the costly gifts of the queen of Sheba. Mr. K. T. Frost (Epis. Times, Jan. 1905) was the first to point out that by his commerce of the trade routes Solomon was able to balance Phœnician and Sabæan exports against each other, and that his Ophir gold would be paid for by trade facilities and protection of caravans.

OPHITES, or OPHIANS (Gr. ὀφίης, Heb. φίης, "snake"), known also as NAESENES, an early sect of Gnostics described by Hippolytus (Philosoph. v.), Irenæus (adv. Haer. i. 11), Origen (Contra Celsum, vi. 25 seq. and Epiphanius (Haer. xxvi.). The account given by Irenæus may be taken as representative of these descriptions which vary partly as referring to different groups, partly to different dates. The honour paid by them to the serpent is connected with the old mythologies of Babylon and Egypt as well as with the popular cults of Greece and the Orient. It was particularly offensive to Christians as tending to dishonour the Creator who is set over against the serpent as bad against good. The Ophite system had its Trinity: (1) the Universal God, the First Man, (2) his conception (Iphoan), the Second Man, and (3) a Snake holy Spirit. From her the Third Man (Christ) was begotten by the First and Second. Christ flew upward with his mother, and in their ascent a spark of light fell on the waters as Sophia. From this contact came Ialdabaoth the Demiurgos, who in turn produced six powers and with them created the seven heavens and from the dregs of matter the Nous of serpent form, from whom are spirit and soul, evil and death. Ialdabaoth then announced himself as the Supreme, and when man (created by the six powers) gave thanks for life not to Ialdabaoth but to the First Man, Ialdabaoth created a woman (Eve) to destroy him. Then Sophia or Prunikos sent the serpent (as a benefactor) to persuade Adam and Eve to eat the tree of knowledge and so break the commandment of Ialdabaoth, who banished them from paradise to earth. After a long war between mankind aided by Prunikos against Ialdabaoth (this is the inner story of the Old Testament), the Holy Spirit sends Christ to the earth to enter (united with his sister Prunikos) the pure vessel, the virgin-born Jesus. Jesus Christ worked miracles and declared himself the Son of the First Man. Ialdabaoth instigated the Jews to kill him, but only Jesus died on the cross, for Christ and Prunikos had departed from him. Christ then raised the spiritual body of Jesus which remained on earth for eighteen months, initiating a small circle of elect disciples. Christ, received into heaven, sits at the right hand of Ialdabaoth, whom he deprives of glory and receives the souls that are his own. In some circles the serpent was identified with Prunikos. There are some resemblances to the Valentinian system, but whereas the great Archon sins in ignorance, Ialdabaoth sins against knowledge; there is also less of Greek philosophy in the Ophite system.

OPHTHALMOLOGY (Gr. ὀφθαλμός, eye), the science of the anatomy, physiology and pathology of the eye (see eye and vision). From the same Greek word come numerous other derivatives: e.g. opthalmia, the general name for conjunctival inflammations (see eye diseases, under eye); and the instruments ophthalmometer and ophthalmoscope (see vision).
OPIE, AMELIA (1769–1853), English author, daughter of James Alderson, a physician in Norwich, and was born there on the 12th of November 1769. Miss Alderson had inherited radical principles and was an ardent admirer of Horne Tooke. She was intimate with the Kembles and with Mrs Siddons, with Godwin and Mary Wollstonecraft. In 1798 she married John Opie, the painter. The nine years of her married life were very happy, although her husband did not share her love of society. He encouraged her to write, and in 1801 she produced a novel entitled *Father and Daughter*, which showed genuine fancy and pathos. She published a volume of graceful verse in 1802; *Adeline Mowbray* followed in 1804, *Simple Tales* in 1806, *Temper* in 1812, *Tales of Real Life* in 1813, *Valentine's Eve* in 1816, *Tales of the Heart* in 1818, and *Madeline* in 1822. At length, in 1825, through the influence of Joseph John Gurney, she joined the Society of Friends, and beyond a volume entitled *Detraction Displayed*, and contributions to periodicals, she wrote nothing more. The rest of her life was spent in travelling and in the exercise of charity. Mrs Opie retained her vivacity to the last, dying at Norwich on the 2nd of December 1853.

A *Life*, by Miss C. L. Brightwell, was published in 1854.

OPIE, JOHN (1761–1807), English historical and portrait painter, was born at St Agnes near Truro in May 1761. He early showed a taste for drawing, besides having at the age of twelve mastered Euclid and opened an evening school for arithmetic and writing. Before long he won some local reputation by portrait-painting; and in 1780 he started for London, under the patronage of Dr Wolcot (Peter Pindar). Opie was introduced to the town as “The Cornish Wonder,” a self-taught genius. The world of fashion, ever eager for a new sensation, was attracted; the carriages of the wealthy blocked the street in which the painter resided, and for a time he reaped a rich harvest by his portraits. But soon the fickle tide of popularity flowed past him, and the painter was left neglected. He now applied himself with redoubled diligence to correcting the defects which marred his art, meriting the praise of his rival Northcote—“Other artists paint to live; Opie lives to paint.” At the same time he sought to supplement his early education by the study of Latin and French and of the best English classics, and to polish the rudeness of his provincial manners by mixing in cultivated and learned circles. In 1786 he exhibited his first important historical subject, the “Assassination of James I.,” and in the following year the “Murder of Rizzio,” a work whose merit was recognized by the artist’s immediate election as associate of the Academy, of which he became a full member in 1788. He was employed on five subjects for Boydell’s *Shakespeare Gallery* (1795). In October of 1807, his practice alternated between portraiture and historical work. His productions are distinguished by breadth of handling and a certain rude vigour, individuality and freshness. They are wanting in grace, elegance and poetic feeling. Opie is also favourably known as a writer on art by his *Life of Reynolds in Wolcot’s edition of Pilkington, his Letter on the Cultivation of the Fine Arts in England, in which he advocated the formation of a national gallery, and his Lectures as professor of painting to the Royal Academy, which were published in 1809, with a memoir of the artist by his widow (see above).

OPINION (Lat. *opinio*, from *opinari*, to think), a term used loosely in ordinary speech for an idea or an explanation of facts which is regarded as being based on evidence which is good but not conclusive. In logic it is used as a translation of Gr. *δόξα*, which plays a prominent part in Greek philosophy as the opposite of knowledge (ἐπιστήμη or ἐπιστήμων). The distinction is drawn by Parmenides, who contrasts the sphere of truth or knowledge with that of opinion, which deals with mere appearance, error, not-being. So Plato places δόξα between *άδοξον* and *διάνοια*, as dealing with phenomena contrasted with non-being and being respectively. Thus Plato confines opinion to that which is subject to change. Aristotle, retaining the same idea, assigns to opinion (especially in the *Ethics*) the sphere of things contingent, i.e. the future: hence opinion deals with that which is probable. More generally he uses popular opinion—that which is generally held to be true (δόξα) —as the starting-point of an inquiry. In modern philosophy the term has been used for various conceptions all having much the same connotation. The absence of any universally acknowledged definition, especially such as would contrast “opinion” with “belief,” “faith” and the like, deprives it of any status as a philosophical term.

OPITZ VON BOBERFELD, MARTIN (1597–1639), German poet, was born at Bunzlau in Silesia on the 23rd of December 1597, the son of a prosperous citizen. He received his early education at the Gymnasium of his native town, of which his uncle was rector, and in 1617 attended the high school—“Schönaichanum”—at Beuthen, where he made a special study of French, Dutch and Italian poetry. In 1618 he entered the university of Frankfort-on-Oder as a student of *literae humaniores*, and in the same year published his first essay, *Arystarchus, sive De contemptu linguæ Teutonicae*, a plea for the modernization of the German language (1618). In 1621 he went to Heidelberg, where he became the leader of the school of young poets which at that time made that university town remarkable. Visiting Leiden in the following year he sat at the feet of the famous Dutch lyric poet Daniel Heinsius (1580–1655), whose *Lobgesang Jesu Christi* and *Lobgesang Bocchi* he had already translated into alexandrines. After being for a short year (1622) professor of philosophy at the Gymnasium of Weissenburg (now Karlsruhe) in Transylvania, he led a wandering life in the service of various territorial nobles. In 1624 he was appointed councillor to Duke George Rudolf of Liegnitz and Brieg in Silesia, and in 1625, as reward for a requiem poem composed on the death of Archduke Charles of Austria, was crowned laureate by the emperor Ferdinand II, who a few years later ennobled him under the title “von Boberfeld.” He was elected a member of the *Fruchtbringende Gesellschaft* in 1629, and in 1630 went to Paris, where he made the acquaintance of Hugo Grotius. He settled in 1635 at Danzig, where Ludisaus IV. of Poland made him his historiographer and secretary. Here he died of the plague on the 20th of August 1639.

Opitz was the head of the so-called First Silesian School of poets (see Germany: Literature), and was during his life regarded as the greatest German poet. Although he would not to-day be considered a poetical genius, he may justly claim to have been the “father of German poetry” in respect at least of its form; his *Buch von der deutschen Poeterey* (1624) put an end to the hybridism that had until then prevailed, and established rules for the “purity” of language, style, verse and rhyme. Opitz’s own poems are in accordance with the rigorous rules he had laid down. They are mostly a formal and sober elaboration of carefully considered themes, and contain little beauty and less feeling. To this didactic and descriptive category belong his best poems, *Trost-Gedichte in Widerwärtigkeiten des Krieges* (written 1621, but not published till 1633); *Zlatna, oder von Ruhe des Gemüts* (1622); *Lob des Feldlebens* (1623); *Vielgut, oder vom wahren Glück* (1629), and *Vesuvius* (1633). These contain some vivid poetical descriptions, but are in the main treatises in poetical form. In 1624 Opitz published a collected edition of his poetry under the title *Acht Bücher deutscher Poematum* (though, owing to a mistake on the part of the printer, there are only five books); his *Dafne* (1627), to which Heinrich Schütz composed the music, is the earliest German opera. Besides numerous translations, Opitz edited (1639) *Das Annotated*, a Middle High German poem of the end of the 11th century, and thus preserved it from oblivion.

Opitz’s collected editions appeared in 1625, 1629, 1637, 1641, 1600 and 1746. His *Ausgewählte Dichtungen* was edited by J. Tittmann (1869) and by H. Oesterley (Kürscher’s *Deutsche Nationalliteratur*, vol. xvii. 1889). There are modern reprints of the *Buch der Mercy für den Braue* (2nd ed., 1882) and, together with *Arystarchus*, by G. Witkowski, 1886; and the *Teutsche Poemata*, of 1624, by G. Witkowski (1902). See H. Palm, *Beiträge zur Geschichte der deutschen Literatur des 16ten und 17ten Jahrhunderts* (1877); K. Borinski, *Die Poetik der Renaissance* (1886); R. Beckermann, *Opitz, Rotmann, und Hesse* (1888). Bibliography by H. Oesterley in the *Zentralblatt für Bibliothekswesen* for 1885.
OPium (Gr. ὄπιος, dim. from ὄψις, juice), a narcotic drug prepared from the juice of the opium poppy, Papaver somniferum, a plant probably indigenous in the south of Europe and western Asia, but now so widely cultivated that its original habitat is uncertain. The medicinal properties of the juice have been recognized from a very early period. It was known to Theophrastus by the name of μεκονίων, and appears in his time to have had an extract of the whole plant, since Dioscorides, about A.D. 77, draws a distinction between μεκονίων, which he describes as an extract of the entire herb, and the more active ὄπιος, derived from the capsules alone. From the 1st to the 12th century the opium of Asia Minor appears to have been the only kind known in commerce. In the 13th century opium thebaicum is mentioned by Simon Januensis, physician to Pope Nicholas IV., while meconium was still in use. In the 16th century opium is mentioned by Pyres (1516) as a production of the kingdom of Coss (Kuch Behar, south-west of Bhutan) in Bengal, and of Malwa. Its introduction into India appears to have been connected with the spread of Islam. The opium monopoly was the property of the Great Mogul and was regularly sold. In the 17th century Kämppfer describes the various kinds of opium prepared in Persia, and states that the best sorts were flavoured with spices and called “theriaka.” These preparations were held in great estimation during the middle ages, and probably supplied to a large extent the place of the pure drug. Opium is said to have been introduced into China by the Arabs probably in the 13th century, and it was originally used there as a medicine, the introduction of opium-smoking being assigned to the 17th century. In a Chinese Herbal compiled before 1700 both the plant and its inspissated juice are described, together with the mode of collecting it, and in the General History of the Southern Provinces of Yunnan, revised and republished in 1736, opium is noticed as a common product. The first edict prohibiting opium-smoking was issued by the emperor Yung Cheng in 1729. Up to that date the amount imported did not exceed 200 chests, and was usually brought from India by junk as a return cargo. In the year 1757 the monopoly of opium cultivation in India passed into the hands of the East India Company through the victory of Clive at Plassey. Up to 1773 the trade with China had been in the hands of the Portuguese, but in 1774 the East India Company took the trade under their own charge, and in 1776 the annual export reached 1000 chests, and 5045 chests in 1790. Although the importation was forbidden by the Chinese imperial authorities in 1766, and opium-smoking punished with severe penalties (ultimately increased to transportation and death), the trade continued and had increased during 1820–1830 to 16,877 chests per annum. The trade was contraband, and the opium was bought by the Chinese from depot ships at the ports. Up to 1830 no effort was made to stop the trade, but in that year the emperor Tao-Kwang sent a commissioner, Lin Tzse-sü, to Canton to put down the traffic. Lin issued a proclamation threatening hostile measures if the British opium ships serving as depots were not sent away. The demand for removal not being complied with, 20,201 chests of opium (of 149 lb each), valued at £2,000,000, were destroyed by the Chinese commissioner Lin; but still the British sought to

FIG. 1.—Opium Poppy (Papaver somniferum).

Chinese Herbal compiled before 1700 both the plant and its inspissated juice are described, together with the mode of collecting it, and in the General History of the Southern Provinces of Yunnan, revised and republished in 1736, opium is noticed as a common product. The first edict prohibiting opium-smoking was issued by the emperor Yung Cheng in 1729. Up to that date the amount imported did not exceed 200 chests, and was usually brought from India by junk as a return cargo. In the year 1757 the monopoly of opium cultivation in India passed into the hands of the East India Company through the victory of Clive at Plassey. Up to 1773 the trade with China had been in the hands of the Portuguese, but in 1774 the East India Company took the trade under their own charge, and in 1776 the annual export reached 1000 chests, and 5045 chests in 1790. Although the importation was forbidden by the Chinese imperial authorities in 1766, and opium-smoking punished with severe penalties (ultimately increased to transportation and death), the trade continued and had increased during 1820–1830 to 16,877 chests per annum. The trade was contraband, and the opium was bought by the Chinese from depot ships at the ports. Up to 1830 no effort was made to stop the trade, but in that year the emperor Tao-Kwang sent a commissioner, Lin Tzse-sü, to Canton to put down the traffic. Lin issued a proclamation threatening hostile measures if the British opium ships serving as depots were not sent away. The demand for removal not being complied with, 20,201 chests of opium (of 149 lb each), valued at £2,000,000, were destroyed by the Chinese commissioner Lin; but still the British sought to smuggle cargoes on shore, and some outrages committed on both sides led to an open war, which was ended by the treaty of Nanking in 1842. The importation of opium continued and was legalized in 1858. From that time, in spite of the remonstrances of the Chinese government, the exportation of opium from India to China continued, increasing from 52,025 piculs (of 133½ lb) in 1850 to 96,830 piculs in 1880. While, however, the court of Peking was honestly endeavouring to suppress the foreign trade in opium from 1839 to 1858 several of the provincial viceroys encouraged the trade, nor could the central government put a stop to the home cultivation of the drug. The cultivation increased so rapidly that at the beginning of the 20th century opium was produced in every province of China. The western provinces of Sze-ch'uen, Yun-nan and Kwei-chow yielded respectively 200,000, 30,000 and 15,000 piculs (of 133½ lb); Manchuria 15,000; Shen-si, Chin-lil and Shan-tung 10,000 each; and the other provinces from 5000 to 500 piculs cach, the whole amount produced in China in 1906 being estimated at 330,000 piculs, of which the province of Sze-ch'uen produced nearly two-thirds. Of this amount China required for home consumption 125,270 piculs, the remainder being chiefly exported to Indo-China, whilst 54,225 piculs of foreign opium were imported into China. Of the whole amount of opium used in China, equal to 22,588 tons, only about one-seventh came from India.

The Chinese government regarding the use of opium as one of the most acute moral and economic questions which a nation they have to face, representing an annual loss to the country of £56,250,000 (3½ chins), decided in 1905 to put an end to the use of the drug within ten years, and issued an edict on the 20th of September 1906, forbidding the consumption of opium and the cultivation of the poppy. As an indication of their earnestness of purpose the government allowed officials a period of six months in which to break off the use of opium, under heavy penalties if they failed to do so. In October of the same year the American government in the Philippines, having to deal with the opium trade, raised the question of the taking of joint measures for its suppression by the powers interested, and as a result a conference met at Shanghai on the 1st of February 1900 to which China, the United States of America, Great Britain, Austria-Hungary, France, Germany, Italy, Japan, the Netherlands, Persia, Portugal and Russia sent delegates. At this meeting it was resolved that it was the duty of the respective governments to prevent the export of opium to any countries prohibiting its importation; that drastic measures should be taken against the use of morphine; that anti-opium remedies should be investigated; and that all countries having concessions in China should close the opium divans in their possessions. The British government made an offer in 1907 to reduce the export of Indian opium to countries beyond the seas by 5100 chests, i.e., 1⁄6th of the amount annually taken by China, each year until the year 1910, and that if during these three years the Chinese government had carried out its arrangements for proportionally diminishing the production and consumption of opium in China, the British government were prepared to continue the same rate of reduction, so that the export of Indian opium to China, as compared with the amount exported in 1907, was to have been reduced severally in the proportions of 3 to 4, and that the restrictions of the imports of Turkish, Persian and other opiums being separately arranged for by the Chinese government, and carried out simultaneously. The above proposal was gratefully received by the Chinese government. A non-official report by Mr E. S. Little, after travelling through western China, which appeared in the newspapers in May 1910, stated that all over the province of Sze-ch'uen opium had almost ceased to be produced, except only in a few remote districts on the frontier (see further China: § History).

The average annual import of Persian and Turkish opium into China is estimated at 1125 piculs, and if this quantity were to be reduced every year by one-ninth, beginning in 1909, in nine years the import into China would entirely cease, and the Indian, Persian and Turkish opiums no longer be articles of commerce in that country. One result of these regulations was that the price of foreign opium in China rose, a circumstance which was calculated to reduce the loss to the Indian revenue.
Thus in 1909-1910, with only 350,000 acres under cultivation and 40,000 chests of opium in stock, the revenue was £4,420,600 as against £3,573,044 in 1905-1906 with 613,096 acres under cultivation and a stock of 76,063 chests. No opium dens have been allowed since 1907 in their possessions or leased territories in China by Great Britain, France, Germany, Russia or Japan.

The difficulties of the task undertaken by the Chinese government to eradicate a national and popular vice, in a country whose population is generally estimated at 400,000,000, are increased by the fact that the opium habit has been indulged in by all classes of society, that opium has been practically the principal if not the only national stimulant; that it must involve a considerable loss of revenue, which will have to be made up by other taxes, and by the fact that its cultivation is more profitable than that of cereals, for an English acre will on the average produce raw dry opium of the value of £5, 16s. 8d. while it will yield grain valued only at £4, 5s. 6d.

Various remedies for the opium habit have been experimented with by China, but with doubtful success. Under the name of anti-opium cure various remedies containing morphine in the form of powder, or of little pills, have been introduced, as well as the subcutaneous injection of the alkaloid, so that the use of morphine is increasing in China to an alarming extent, and considerable difficulty is experienced in controlling the illicit traffic in it, especially that sent through the post. Its comparative cheapness, one dollar's worth being equal to three dollars' worth of opium in the effect produced, its portability and the facilities offered in obtaining it, are all in its favour.

A good deal of morphine is exported to Japan from Europe, and generally passes into China by way of Manchuria, where Japanese products have a virtual monopoly. The effects of morphine are much more deleterious than those of opium-smoking. The smoke of opium, as shown by H. Molissan, contains only a trifling amount of morphine, and the effect produced by it is apparently due, not to that alkaloid, but to such decompositions of products as procol, acetone and pyridine and hydro-pyridine bases. F. Browne finds that after smoking "chando," containing 8-98% of morphine, 7-63% was left in the dross, so that only 1.33% of morphine was carried over in the smoke or decomposed by the heat.

For many years two Scotch firms, Messrs. J. D. Macfarlan and T. and H. Smith of Edinburgh, and T. Whiffen of London manufactured practically the world's supply of this alkaloid, but it is now made in the United States and Germany, although the largest amount is still probably made in Great Britain. A small amount of morphine and codeine is also manufactured in India for medicinal use. The prohibition of the general importation of morphine into China except on certain conditions was agreed to by the British government in Act X XI of the Mackay treaty, but only came into force on the 1st of January 1905. Unless the indirect importation of morphine into China from Europe and the United States is stopped, a worse habit and more difficult to cure than any other (except perhaps that of cocaine) may replace that of opium-smoking in China. It is worse even than opium-eating, in proportion as morphine is more active than opium. The sale and use of morphine in India and Burma is now restricted. The quantity of morphine that any one may legally possess, and then only for medicinal purposes, is in India 10 grams and, in Burma 5. The possession of morphine by medical practitioners is also safeguarded by well-defined limitations.

Production and Commerce.—Although the collection of opium is possible in all places where there is not an excessive rainfall and the climate is temperate or subtropical, the yield is smaller in temperate than in tropical regions and the industry can only be profitably carried on where labour and land are sufficiently cheap and abundant; hence production on a large scale is limited to comparatively few countries. The varieties of poppy grown, the mode of cultivation adopted and the character of the opium produced differ so greatly that it will be convenient to consider the opiums of each country separately.

Turkey.—The poppy cultivated in Asia Minor is the variety glabrum, distinguished by the sub-globular shape of the capsule and by the stigmata or rays at the top of the fruit being ten or twelve in number. The flowers are usually of a purplish colour, but are sometimes white, and the seeds, like the petals, vary in tint from dark violet to white. The cultivation is carried on, both on the mountaneous and on the plains, and is an old and extensive one. A naturally light and rich soil, further improved by manure, is necessary, and moisture is indispensable, although injurious in excess, so that after a wet winter the best crops are obtained on hilly ground, which is left dry after harvest and begins to dry again in the second time, so that it may be thoroughly pulverized; and the seed, mixed with four times its quantity of sand, to prevent its being sown too thickly, is scattered broadcast, about 1 to 2 lb. per acre (3600 to 7200) square feet. The crop is very uncertain owing to droughts, spring frosts and raids, in order to avoid a total failure and to allow time for collecting the produce, there are three sowings at intervals from October to March and the crops thus coming to perfection in succession. But notwithstanding these precautions the quantities of the drug produced when the crop is a full one, owing to the difficulty of gathering the whole in the short time during which collection is possible. The first sowing produces the hardest plants, the yield of the other two is to some extent compensate for the loss of the first by the increase of purity, as the others, though matured later, are usually passed through a different series of processes. The petals fall in a few hours, and the capsules grow so rapidly that in a short time—from nine to fifteen days—the opium is fit for collection. This period is known by the capsules yielding to pressure, and this is attended with the appearance of a cloudy mass, exhibiting a kind of bloom called "cough," easily rubbed off with the fingers; they are then about 14 in. in diameter. The incisions are made by holding the capsule in the left hand and drawing a knife (2) or (3) of the letters shaped in the outside in a circular manner, with the first or second circle or "chequis" being incised. The great care being taken not to let the incisions penetrate to the interior lest the juice should flow inside and be lost. In this case also it is said that the seeds will not ripen, and that no oil can be obtained from them. The capsule is then dried in the sun for from the heat of the day, commencing early in the afternoon and con- tinuing to nightfall, and the exuded juice is collected the next morning. This is done by scraping the capsule with a knife and collecting the exuded juice in the left hand, and the edges of the leaf being turned in to avoid spilling the juice, and the knife-blade moistened with saliva by drawing it through the mouth after every alternate scraping to prevent the juice from adhering to it. When as much opium has been collected as the size of the leaf will allow, another leaf is wrapped over the top of the lump, which is then placed in the shade to dry for several days. The pieces vary in size from about 2 oz. to 2 lb., being made larger and more bulky as they are more distant from the source of supply. The pieces thus incised only once but the fields are visited a second or third time to collect the opium from the poppy-heads subsequently developed by the branching of the stem. The yield of opium varies, even on the same piece of land, from 1/2 to 3/4 chequis (of 1600 lb) per tolooom (1600 lb) to 1/2 to 3/4 bushels (of 50 lb) of seed. The seed, which yields 35 to 42% of oil, is worth about two-thirds of the value of the opium. The whole of the operation must, of course, be completed in the few days' five to ten—during which the carpoporous capsule of the fruit is ready to be collected by hand. A cold wind or a chilly atmosphere at the time of collection lessens the yield, and rain washes the opium off the capsules. Before the crop is all gathered a meeting of buyers and sellers takes place, at which the various district prices are fixed and settled, and the opium handed to the buyers, who in many instances have advanced money on the standing crop. When sufficiently solid the pieces of opium are packed in cotton bags, a quantity of each being placed in the front of the bag. After the cakes are transported in trains the buyers collect them at the places of discharge from the various houses to avoid loss of weight until sold. The opium is then of a mixed character and is known as taleque. When transferred to the buyer's warehouses the bags are opened and each piece is examined by the buyer, who has previously engaged the seller, the quality of the opium being judged by appearance, odor, colour and weight. It is then sorted into three qualities: (1) finest quality; (2) current or second; (3) chiciante or rejected piles. Owing to the extreme variation of size the weight of both the large and the small pieces is estimated. The substances used to adulterate opium are grape-juice thickened with flour, fig-paste, liqueurice, half-dried apricots, inferior gum tragacanth and sometimes clay or pieces of lead or other metals. The chiciante is returned to the seller, who disposes of it at 20 to 30% discount to French and German merchants. After inspection the opium is hermetically sealed in tin-lined boxes containing about 150 lb. Turkey opium is principally used in medicine.
on account of its purity and the large percentage of morphia that it contains, a comparatively small quantity being exported for smoking purposes.

About three-quarters of the opium prepared in Turkey is produced in the districts of Smyrna, and is exported by way of Smyrna. The remainder is produced in the hilly districts of the provinces near the southern coast of the Black Sea, and finds its way into Constantinople, the commercial varieties bearing the name of the district of origin and the name of the seller. In this way the produce of Ahum Karahissar, Uschak, Akhisars, Taoushanli, Isbarta, Konia, Bulvadan, Hamid, Magnesia and Yerli, the last name being applied to opium collected in the immediate neighbour- bull to Konia. The opium exported by way of Constantinople includes that of Hadjidej and Malatia; the Tokat kind, of good quality, including that produced in Yagods, Sile and Niksar, and the current or second quality derived from Amasia and Oerek, the factors of which are informed the authorities of the white-flowered poppy (Papaver rhoeas) and the yellow or white poppy (Papaver somniferum), the former being described as the more abundant opium of superior quality. The yellow seed is said to yield the best oil; that obtained by hot pressure is used for lamps and for paint, and the cold-pressed oil for culinary purposes.

The average amount of Turkish opium exported annually, as calculated in chests, is about 1% of the domestic production, the Western commercial countries, with the exception of Russia, taking up to 1% of the total production. The Russian purchases are made at Odessa and the other Russian ports.

India.—The poppy grown in India is usually the white-flowered variety, but in the Himalayas a red-flowered poppy with dark seeds is cultivated. The opium industry in Bengal is a government monopoly, the opium being cultivated and exported respectively at Patna and Ghazipur. Any one may undertake the opium industry, but cultivators are obliged to sell the opium exclusively to the government at a fixed price before hand, the latter, which changes from time to time, fluctuates

1 Ghévé is the commercial name for opium from Geveh on the river Sakia, running into the Black Sea. It appears to find its way to Constantinople via the port of Ismail, and hence is known also by the latter name.
Various other adulterants are sometimes used, such as the inspissated juice of the prickly pear, extracts from tobacco, stramonium and hemp, pulp of the tamarind and bael fruit, mahaw flowers and gums of different kinds. The price paid to the cultivator is regulated chiefly by the colour and consistence of the powder, and once it has been received into the government stores the opium is kept in large wooden boxes holding about 50 maunds and occasionally stirred up, if only a little below the standard. If containing much water it is removed into shallow wooden drawers and constantly turned over. During the process it deepens in colour. From the store about 250 maunds are taken daily to be manufactured into cakes.

Portions, each weighing 10 sees (or 2 lb.), are selected by the government after being sorted so as to include the best maund of mixture (70% of the pure dry drug and 30% of water), and are thrown into shallow drawers and kneaded together. The mass is then packed into boxes all of one size, and a specimen of each again assayed, the mean of the whole being taken as the average. Before evening these boxes are emptied into wooden vats 2 ft. wide and 1 ½ ft. deep, and the opium further kneaded and mixed by men washing through it from end to end until it appears to be of a uniform consistence. Next morning the manufacture of the opium into balls commences. The workman sits on a wooden stool, with a brass cup before him, which he lines with the leaves of poppy petals before-mentioned until the thickness of half an inch is reached, a few being allowed to hang over the cup; the leaves are agglutinated to the ball by a viscid gum or paste, which forms a mixture of inferior opium, 8% of “pussewah” and the “choo” or washings of the vessels that have contained opium, and the whole is made of such consistence that 100 grains evaporated to dryness over a water-bath leave 53% of a residue. The dried opium balls are then subjected to a series of tests by which the quality of the opium-ball are furnished to the workmen by measure. When the inside of the brass cup is ready a ball of opium previously weighed is placed on the leafy case in it, and the upper half of it covered with leaves. When the leafy case is the same weight as the water-bath and the overhanging leaves of the lower half being pressed upwards and the sphere completed by one large leaf which is placed over the upper half. The ball, which resembles a Dutch cheese in size and shape, is now rolled in “poppy powder” and kneaded into powdered leaves, capsules and stalks of the poppy plant, and is placed in an earthen cup of the same size as the brass one; the cups are then placed in dishes and the opium exposed to the sun to dry for two days, being examined and examined daily, if it becomes destituted the ball is pierced to liberate the gas and again lightly closed. On the third evening the cups are placed in open frames which allow free circulation of the air. This operation is usually completed by the end of July. The balls thus made consist on an average of—

The average number of cakes that can be made daily by one man is about 70, although 90 to 100 are sometimes turned out by clever workmen. The cakes are liable to be become moulded, and require constant attention to prevent the Kum Killa (small seed of this plant) or a small quantity of “pussewah” to remove the mildew, and strengthening in weak places with fresh poppy leaves. By October the cakes are dry and fairly solid, and are then packed in chests, which are divided into two tiers of twenty square compartments for the reception of as many cakes, which are steadied by a packing of loose poppy trash. Each case contains about 120 catties (about 160 lb.). The chests need to be kept in a dry warehouse for a length of time, but ultimately the opium leaves moisture to the shell, and the latter becomes extremely solid.

The care bestowed on the selection and preparation of the drug in the Bengal opium-factories is such that the merchants who purchase it rarely require to examine it, although permission is given to open at any time the receptacles containing it to its buyers.

In Malwa the opium is manufactured by private enterprise, the government levying an export duty of 600 rupees (£60) per chest. It is not made into balls but into rectangular or rounded masses, which are not favourably received, and are sold at an average of £1 or £1.50 per mile of dry opium, but is of much less uniform quality than the Bengal drug, and, having no guarantee as to purity, is not considered so valuable. The cultivation in Malwa does not differ in any important particular from that in Bengal; the maha is gathered in March and April, and the crude drug or “chick” is thrown into an earthen vessel and covered with linseed oil to prevent evaporation. In this state it is sold to itinerant dealers. It is afterwards tied up in quantities of 25 lb. and 50 lb. and sent to the merchants of cotton. It contains about 10% of the light and draught to allow the excess of oil to drain off. This takes place in seven to ten days, but the bags are left for four to six weeks until the oil remaining on the opium has become oxidized and hardened. In June and July, when the rains begin, the bags are taken down and emptied

1 This is purchased from the ryots at 12 annas per maund.

OPIUM also contains a gum, pectin, a wax, sugar and similar substances, in addition to meconic and lactic acids.

The alkaloids fall into two chemical groups: (1) derivatives of isooquinoline, including papaverine, narceine, goscapine (racemic narcotine), narceine, laudanosine, laudanine, cotanine, and (2) derivatives of phenanthrene, including morphine, codeine, thebaine. The constituents of the first series have been determined; of the second they are still uncertain.

Papaverine, CaH$_4$NO$_4$, was investigated by G. Goldschmidt (Monats., 1883-1889), who determined its constitution (formula I., below) by a study of its oxidation products, showing that papaverine, which gives with potassium permanganate, is a tetra-methoxybenzylisoquinoline. Its synthesis, and also that of laudanine, C$_{12}$H$_{10}$NO$_4$, which is a N-methyltetrahydropapaverine, was effected in 1909 by F. L. Pyman (Jour. Chem. Soc., 95, p. 1610) and by A. J. Acton and C. W. C. Hood (Jour. Amer. Chem. Soc., 31, p. 925). Laudanine, C$_{12}$H$_{10}$NO$_4$, is very similar to laudanosine, differing in having three methoxy groups and one hydroxy instead of four methoxy.

Narcotine, C$_{14}$H$_{18}$N, has been principally investigated by A. Matthiessen and G. C. Foster, and by W. Roser (Ann. 1888, 249, p. 156; 1889, 254, p. 334.) By hydrolysis it yields opiumic acid, C$_{14}$H$_{16}$O$_4$, and hydrocotarine, C$_{13}$H$_{10}$NO$_4$; reduction gives meconine, C$_{14}$H$_{18}$N, and hydrocotarine; while oxidation gives opiumic acid and meconine, C$_{14}$H$_{18}$N, and hydrocotarine.

Hydrosolubuline (II) (hydrastine, the alkaloid of golden seal. Hydrostis canadensis, was solved by E. Schmidt, M. Freund, and P. Frisch) and cotarine to be III; the latter has been synthesized by A. H. Saltz (Ann. 517, 121, 1917). A. H. Saltz (Ann. 517, 121, 1917) and others obtained by the action of potash on the methyl iodide of narcotine is probably IV. (see Pyman, loc. cit. p. 1266, 1728; M. Freund and P. Oppenheim, Ber., 1909, 42, p. 1084).

The proprietary drug "stypnic acid" is cotarine hydrochloride, and "crystall" cotarine phthalate; "antisapinum" is a sodium narcine combined with sodium salicylate, and "narcyl" narcine ethylhydrochloride.

The chemistry of morphine, codeine, and thebaine is exceedingly complicated, and the literature enormous. That these alkaloids are closely related may be suspected from their empirical formulae, viz. morphine = C$_{14}$H$_{18}$N$_2$O$_2$, codeine = C$_{14}$H$_{18}$N$_2$O$_2$, thebaine = C$_{14}$H$_{18}$N$_2$O$_2$. As a matter of fact, Grimau, in 1881, showed codeine to be thebaine hydrolysed, and Hooz and L. Knorr, in 1906, obtained identical substances, viz. thebaine and morphine, thebaine, from both codeine and thebaine, thereby establishing their connexion. Our knowledge of the constitution of these alkaloids largely depends on the researches of M. Freund, E. Van den Elsen, L. Knorr and R. Pschorr. The presence of the phenanthrene nucleus and the chain system CH$_2$N-C-C follows from the fact that these alkaloids, by appropriate treatment, yield a substituted phenanthrene and also dimethyloxymethanol (CH$_3$N-CH$_2$O-CH$_3$). Formulas have been proposed by Pschorr and Knorr explaining this and other decompositions (in Pschorr's formula the morphine ring system is a fusion of a phenanthrene and pyridine nucleus); another formula, containing a fusion of a phenanthrene with a pyrrol ring, was suggested by Bucherer in 1917. The problem is discussed by Pschorr and Einbeck (Ber., 1907, 40, p. 1980), and by Knorr and Hörlein (ibid. p. 2042); see also Ann. Reps. Chem. Soc.

Morphine, or morphia, crystallizes in prisms with one molecule of water; it is soluble in water and in almost all hydrochloric acid; it forms delicate needles. Distilled with zinc dust morphine yields phenylmorphan, pyridine and quinoline; dehydration gives, under certain conditions, apomorphine, C$_{14}$H$_{18}$N$_2$O$_2$, a white amorphous substance, readily soluble in alcohol. The drug "hefemorphan" is a diacetyl morphan hydrochloride. Codeine, or codeia, crystallizes in orthorhombic prisms with one molecule of water; it is readily soluble in alcohol, ether and chloroform.

Thebaine forms silky plates, melting at 193°. (C. F.)

Medicine.—Of the opium alkaloids only morphine and codeine are used to any extent in medicine. Thebaine is not so used, but is an important and sometimes very dangerous constituent of the various opium preparations, which are still largely employed, despite the complexity and inconstant composition of the drug. Of the other alkaloids narcotine is hypnotic, like thebaine, codeine, and morphine. Papaverine and narcotine have an action which resembles that of acetylcholine, but is generally speaking, undesirable or dangerous if at all well marked. A drug of so complex a composition as opium is necessarily incompatible with a large number of substances. Tannic acid, for instance, precipitates codeine as a tannate, salts of many of the heavy metals form precipitates of meconates and sulphates, whilst the various alkalies, alkaline carbones and ammonia precipitate the important alkaloids.

The pharmacology of opium differs from that of morphine (q.v.) in a few particulars. The chief difference between the action of opium and morphine is due to the presence in the former of the two opium toxins, laudanum and morphine, the latter is relatively inactive in young children. In infants especially opium acts markedly upon the spinal cord, and, just as strychnine is dangerous when given to young children, so opium, because of the strychnine-like action of thebaine, should never be administered, under any circumstances or in any dose, to children under one year of age.

When given by the mouth, opium has a somewhat different action from that of morphine. It often relieves hunger, by arresting the feelings of pain, and is constipating, a fact which is also observed when it acts on the spinal cord. It is highly fermented in the intestine, and it frequently upsets digestion from the same cause. Often it retards vomiting, though in a few persons it may cause vomiting, but in less degree than apomorphine, which is a much more powerful emetic, though not so much an emetic as apomorphine is.

There are a few therapeutical indications for the use of opium rather than morphine, but they are far less important than those which make the opposite demand. In some abdominal conditions, for instance, opium is still preferred by the majority of practitioners, but though certainly not in gastric cases, where morphine gives the relief for which opium often increases the need, owing to the irritant action of some of its constituents. Opium is often preferred to morphinic analgesics for women and children, because it is less liable to cause deep diuresis and quiets the entire nervous system in such cases. The fluid is often known as "paregoric" and is also largely used in bronchial conditions, and morphine shows no sign of displacing it in favour. Opium rather than morphine is also usually employed to relieve the pain of haemorrhoids or fissure of the rectum. This practice is, however, obsolescent.

The alkaloid thebaine may be here referred to, as it is not used separately in medicine. Crum Brown and Fraser of Edinburgh believe that thebaine acts like curara, paralysing the terminals of motor nerves. At present we say of such a substance as thebaine, "it acts on the anterior cornua of grey matter in the spinal cord," but why on them and not on the posterior cornua, or on the cornua as a whole, cannot be determined. The same difficulty is met with in the case of other "pin-point" poisons. The heart's action is feeble, the pulse being small, irregular and often abnormally slow. The action on the circulation is largely secondary, however, to the all-important action of opium on the respiratory centre in the medulla oblongata. The respiratory centre is, indeed, more promptly affected through its opium-containing blood, and the patient's breathing becomes progressively slower, shallower and more irregular until finally it ceases altogether.

Toxicology.—Under this heading must be considered acute poisoning by opium, and the chronic poisoning seen in those who eat or smoke the drug. Chronic opium poisoning by the taking of laudanum—i.e., in the familiar case of De Quincey—need not be considered, as the hypodermic injection of morphine has almost entirely supplanted it.

The acute poisoning presents a series of symptoms which are only with difficulty to be distinguished from those produced by alcohol, by cerebro-spinal fever, and by haemorrhoids or other morbid conditions. The differential diagnosis is of the highest importance, but very frequently time alone will furnish a sufficient criterion. The patient has not swallowed a toxic or lethal dose of laudanum, for instance, usually cases of such leading to death the patient has experienced excitement. Intense drowsiness yields to sleep and coma which ends in death from failure of the respiration. This last is the cardinal fact in determining treatment. The comatose patient has a cold, imposed a deep sleep, and the pupils are small and "pin-point." The heart's action is feeble, the pulse being small, irregular and often abnormally slow. OPIUM (X.)

half an hour, since some of the opium is excreted into the stomach after its absorption into the blood. If apomorphine is obtainable, both of these measures may be employed. Potassium permanganate decomposes morphone by oxidation, the action being facilitated by the addition of a small quantity of mineral acid to the solution. The physiological as well as the chemical antidotes must be used. The chief of these are coffee or caffeine and atropine. A pint of hot strong coffee may be introduced into the rectum, and caffeine in large doses—ten or twenty grains of the carbonate may be given by mouth. A twentieth, even a tenth of a grain of atropine, when administered subcutaneously, the drug being a direct stimulant of the respiratory centre. Every means must be taken to keep the patient awake. He must be walked about, have smelling salts constantly applied to the nose, or a stimulating stimulant administered. Withal, the mildest of opium poisoning is artificial respiration, which should be persevered with as long as the heart continues to beat. It has, indeed, been asserted that, if relays of trained assistants are at hand, no one need die of opium poisoning, even if artificial respiration has to be continued for hours or days.

Opium-eating.—Opium, like many other poisons, produces after a time a less effect if frequently administered as a medicine, so that the dose has to be constantly increased to produce the same result on those who take it habitually. When it is used to relieve pain or diarrhoea, if the dose be not taken at the usual time the symptoms of the disease recur with such violence that the remedy is speedily resorted to as the only means of relief, and thus the habit is exceedingly difficult to break off. Opium-eating is chiefly practised in Asia Minor, Persia and India. Opinions differ widely as to the injurious effect of the habit; the weight of evidence appears, however, to indicate that it is much more deleterious than opium-smoking.

The following statistics collected by Vincent Richards regarding Balasar in Orissa throw some light on the influence of this practice on the people, when large had been increased in the country. Every inhabitant of the large population uses the drug, and that the habit is increasing. Of the 1,13 opium-eaters examined by him he found that the average age at which the habit was commenced was 20 to 26 years for men and 24 to 30 years for women. Of this number 1,13 had taken the drug for five to ten years, 62 for from 20 to 30 years and 38 for more than 30 years. The majority took their opium twice daily, morning and evening, the quantity taken varying from 2 to 40 grains daily, large doses being the exception, and the average 5 to 7 grains. The dose was increased rapidly when started, and slowly when small, there used to be an increase at all. The causes which first led to the increase of the drug were disease, example and a belief in its aphrodisiac properties. The diseases for which it was chiefly taken were dysentery, diarrhoea, constipation, bilious fever, rheumatism and elephantiasis. A number began to take it in the famine year, 1866, as it enabled them to exist on less food and mitigate their sufferings; others used it to enable them to undergo fatigue and to make long journeys. That the Indians continued to use the drug in excess because of the agricultural classes, who are the chief consumers in Orissa, is very rare indeed. Its moderating use may be and is indulged in for years without producing any decided or appreciable ill effect except weakening the reproductive powers, the average number of the children of opium-eaters being 11 after 11 years of married life. It compares favourably as regards crime and insanity with intoxicating drinks, the inhabitants of Balasar being a particularly law-abiding race, and the insane forming only 0.006% of the population of Dry漂流 of Balasar.

India, concurs in Richards' opinion regarding the moderate use of the drug. He believes that excessive indulgence in it is confined to a comparatively small number of the wealthier classes of the community. Dr Moore's experience is similar. He found it probable that violent physical exercise may counteract in great measure the deleterious effect of opium and prevent it from retarding the respiration, and that in such cases the beneficial effects are obtained without the noxious effects which would accrue to those indulging in sedentary pursuits. There is no doubt that the spread of the practice is connected with the ban imposed in Mohammedan countries on the use of alcoholic beverages, and to some extent with the long religious fasts of the Buddhists, Hindus and Moslems, in which opium is so much desired.

To break off the habit of opium-eating is exceedingly difficult, and can be effected only by actual external restraint, or the strongest effort of a powerful will, especially if the dose has been gradually increased.

Opium-smoking.—This is chiefly practised by the inhabitants of China and the islands of the Indian Archipelago, and in countries where Chinese are largely employed. Opium-smoking began in China in the 17th century. Foreign opium was first imported by the Portuguese (early 18th century). In 1606 it was estimated that 13,435,000 of Chinese smoked opium, or 27% of adult males; but during 1908-1910 the consumption of opium is believed to have diminished by about one-third.

For smoking the Chinese use an extract of opium known as "opium tea." A crude preparation is made from 60% used opium known as "opium tea," and 40% native opium. The latter is chiefly used by the poorer classes.

The process of preparation is thus described by Hugh M'Callum, government analyst at Hong-Kong:

"The opium is removed from its covering of leaves, &c., moistened with a little water, and allowed to stand for about fourteen hours; it is then enveloped in an earthenware or calico cloth, and inserted into the fire until the saliva of water going to each pan; it is now boiled and stirred occasionally until a uniform mixture having the consistency of a thin paste is obtained. This operation takes five or six hours. The paste is then taken off the fire and passed through 3 gallons, covered and allowed to stand for fourteen to fifteen hours. A bunch of 'tang sani' (lamp-wick, the pith of Eriocaulon or Scirpus) is then inserted well into the mass, and the pan slightly cooled, while of producing well-marked physiological results, are morphine, codeine and narinine. Morphine, in the pure state, can be sublimed, but codeine and narinine are said not to give a sublim.

If even sublimed in smoking opium, morphine would, in M'Callum's opinion, probably be deposited in the pipe before it reached the smoker's lungs. The machine is not a very noticeable when smoking opium, and it is therefore possible that the pleasure derived from smoking the drug is due to some product formed during combustion. This supposition is rendered probable by the fact that the free bases of the alkaloids, or those containing most morphine, and that the quality is judged by the amount of soluble matter in the opium, by its tenacity or 'touch,' and by peculiarities of aroma—the Indian opium, especially the Patna kind, bearing no resemblance at all to the Chinese and the indiarubber tradition as to the drug, to new chemicists. Opium-smoking is thus described by Theo. Sampson of Canton:

"The smoker, lying on his side, with his face towards the tray and his head resting on a high pillow (sometimes made of earthenware, or more often made of leather), takes the pipe in his hand; with the opposite hand he takes a dipper and puts the sharp end of it into the opium, which is of a treacly consistency. Twisting it round and round he gets a large drop of the fluid to adhere to the dipper; still twisting it round to prevent it falling he brings the drop over the flame of the lamp, and twirling it round and round he roasts it; all this is done with acquired dexterity. The opium must not be burnt or made too dry, but roasted gently till it looks burnt worstly; every now and then he takes it away from the flame and rolls it (still on the end of the
dipper) on the flat surface of the bowl. When it is roasted and rolled to his satisfaction it gently heats the centre of the bowl, where there is a small orifice; then he quickly thrusts the end of the dipper into the orifice, twirls it round smartly and withdraws it; if this is properly done, the orifice (about the size of a grain of hemp-seed or a little larger) is left adhering to the bowl immediately over the orifice. It is now ready for smoking.

"The smoker assumes a comfortable attitude (lying down of course) at a proper distance from the lamp. He now puts the stem to his lips, and holds the bowl over the lamp. The heat causes the opium to frizzle, and the smoker takes three or four long inhalations, all the time using the dipper to bring every particle of the opium to the orifice as it burns away, but not taking his lips from the stem. The opium is thus gradually swallowed, and is exhaled through both the mouth and the nose."

So far as can be gathered from the conflicting statements published on the subject, opium-smoking may be regarded much in the same light as the use of alcoholic stimulants. To the great majority of smokers, it is perfectly agreeable, and they continue it as a matter of course, and to enable them to undergo great fatigue and to go for a considerable time with little or no food. According to the reports on the subject, when the smoker has plenty of active work to do, he finds it an agreeable stimulant, and it is then used as a sort of medicine.

The effect in bad cases is to cause loss of appetite, a leaner pallor of the skin, and a degree of leanness so excessive as to make its victims appear like living skeletons. All inclination for exertion becomes gradually lost, business is neglected, and certain ruin to the smoker follows. There can be no doubt that the use of the drug is opposed by all thinking Chinese who are not peculiarly interested in the opium trade or cultivation, for several reasons, among which may be mentioned the drain of bullion from the country, the decrease of the population, the liability to taint through the cultivation of opium where cereals should be grown, and the corruption of state officials.

OPLADEN—OPORTO

OPLADEN, a town of Germany, in the Prussian Rhine Province, 10 m. N.E. from Cologne by the railway to Elberfeld and at the junction of the lines to Speldorf and Bonn. Pop. (1905) 6338. It has an Evangelical and a Roman Catholic church. It has dyeing works, and manufactures of damask, indigo products and railway plant. Before passing to Prussia, Opladen belonged to the duchy of Brabant.

OPON, a town of the province of Cebu, Philippine Islands, on the small island of Macan (area about 45 sq. m.), which is separated from the island of Cebu by a channel only about 1 m. wide. Pop. (1903) after the annexation of Cordova and Santa Rosa, 20,166. There are forty-four barrios, or villages, in the town, and three of these had in 1903 more than 1000 inhabitants each. The language is Visayan. Opon is a shipping and commercial suburb of Cebu city, the harbour of which is sheltered by Mactan Island. The town has large groves of coco-nut trees, and its principal industries are the cultivation of Indian corn and mangoy and fishing. In the N.E. part of the town is a monument to Magellan, who discovered the Philippines in March 1521, and was slain here by the natives late in the following month.

OPORTO (i.e. oporto, "the port"), the second city of the kingdom of Portugal, the capital of the district of Oporto and formerly of Entre-Douro-e-Minho; on both banks of the river Douro, about 3 m. from its mouth, in 41° 8' N. and 8° 37' W. Pop. (1900) 167,955. In Portuguese the definite article is uncompleted in the name of the city, which in strict accuracy should always be written Porto; the form Oporto has, however, been stereotyped by long usage in English and in some other European languages. The part of the city south of the Douro is known as Villa Nova de Gaia. Oporto is the see of a bishop in the archiepiscopal province of Braga. It is the true capital of northern Portugal, and the commercial and political rival of Lisbon, in much the same way as Barcelona (q.v.) is the rival of Madrid. Three main railway lines meet here— from Lisbon, from Vila Nova do Minho on the northern frontier, and from Barca d'Alva on the north-western frontier. The Vila Nova do Minho has branches to Guimarães and Braga, and affords access to Corunna and other cities of north-western Spain; the Barca d'Alva line has a branch to Mirandella and communicates with Madrid via Salamanca. Oporto is built chiefly on the north or right bank of the Douro; its principal suburbs are Bomfin on the E., Monte Pedral and Paranhos on the N., Villar Bicalho, Lordello and Sao Joao da Foz on the W., Ramalde, Villarinha, Matozinhos, Leça da Palmeira and the port of Leixões on the N.W. The mouth of the river is obstructed by a sandy spit of land which has been enlarged by the deposits of silt constantly washed down by the swift current; on the north side of this bar is a narrow channel varying in depth from 16 ft. to 19 ft. A fort in Sao Joao da Foz protects the entrance, and there is a lighthouse on a rock outside the bar. As large vessels cannot enter the river, a harbour of refuge has been constructed at Leixões (q.v.).

The approach to Oporto up the winding and jerd-like estuary is one of singular beauty. On the north the streets rise terraces up the steep bank, built in many cases of granite overlaid with plaster, so that white is the prevailing colour of the city; on the south are the hamlets of Gaia and Furada, and the red-tiled wine lodges of Villa Nova de Gaia, in which vast quantities of "port" are manufactured and stored. The architecture of the houses and public buildings is often rather Oriental than European in appearance. There are numerous parks and gardens, especially on the outskirts of the city, in which palms, oranges and aloes grow side by side with the flowers and fruits of northern Europe, for the climate is mild and very equable, the mean temperatures for January and July—the coldest and the hottest months—being respectively about 50° and 70°. The Douro is at all seasons crowded with shipping, chiefly small steamers and large sailing vessels. The design of some of the native craft is peculiar—among them may be mentioned the high-prowed canoe-like fishing boats, the roscaes with their three luten sails, the globe-bulb shaped quintaos, or to which barges have large rudders, used for the conveyance of wine down stream. Two remarkable iron bridges, the Maria Pia and the Dom Luiz I, span the river. The first was built by Messrs Eiffel & Company of Paris in 1876-1877; it rests on a granite substructure and carries the Lisbon railway line across the Douro ravine at a height of 200 ft. The second, constructed in 1881-1885 by a Belgian firm, has, two decks or roadways, one 33 ft., the other 200 ft. above the usual water-level; its arch, one of the largest in Europe, has a span of 560 ft. and is supported by two massive granite towers. The Douro is liable in winter to sudden and violent floods; in 1909-1910 the water rose 40 ft. at Oporto, where it is confined in a deep and narrow bed.

Though parts of the city are modern or have been modernized, the older quarters in the east are extremely picturesque, with their steep and narrow lanes overshadowed by lofty balcony houses. Overcrowding and dirt are common, for the density of population is nearly 13,000 per sq. m., or greater than in any other city of Portugal. Until the early years of the 20th century, when
a proper system of sewerage was installed, the condition of Oporto was most insanitary. Electric lighting and tramways were introduced a little before this, but the completion of the tramway system was long delayed, and in the 19th century cars driven by ten mules were not an uncommon sight. Ox-carts are used for the conveyance of heavy goods, and until late in the 19th century sedan-chairs were still occasionally used. A painful feature of the street-life of Oporto is the great number of the diseased and mutilated beggars who frequent the busiest thoroughfares. As a rule, however, the natives of Oporto are strong and of fine physique; they also show fewer signs of negro descent than the people of Lisbon. Their numbers tend to increase very rapidly; in 1864 the population of Oporto was 86,751, but in 1878 it rose to 105,838, in 1890 to 138,860, and in 1900 to 167,955.

Many of the men emigrate to South America, where their industry usually enables them to prosper, and ultimately to return with considerable savings. The local dialect is broader than the Portuguese of the educated classes, from which it differs more in pronunciation than in idiom. The poverty of the people is very great. Out of the 597,955 inhabitants of the district of Oporto (893 sq. m.), 422,320 were returned at the census of 1900 as unable to read or write. Much had been done, however, to remedy this defect, and besides numerous primary schools there are in the city two schools for teachers, a medical academy, polytechnic, arts, trade and naval schools, and an industrial institute, a gymnasium, an atheneum, a lyceum for secondary education, an ecclesiastical seminary, and a meteorological observatory.

The cathedral, which stands at the highest point of eastern Oporto, on the site of the Visigothic citadel, was originally a Romanesque building of the 12th century; its cloisters are Gothic of the 14th century, but the greater part of the fabric was modernized in the 17th and 18th centuries. The interior of the cloisters is adorned with blue and white tiles, painted to represent scenes from the Song of Solomon. The bishop's palace is a large and lofty building consequently placed on a high rock; the interior contains a fine marble staircase. The Romanesque and early Gothic church of São Martinho de Cedo Feita is the most interesting ecclesiastical building in Oporto, especially noteworthy being the curiously carved capitals of its pillars. Though the present structure is not older, except in details, than the 12th century, the church is said to have been "hastily built" (cedo feita, cito facta) by Theodomir, king of the Visigoths, in 559, to receive the relics of St. Martin of Tours, which were then on their way hither from France. The Torre dos Clerigos is a granite tower 246 ft. high, built in the middle of the 18th century at the expense of the merchant and bishop D. Afonso de Oporto. Of Gothic origin (1230) it stands on a hill and forms a conspicuous landmark for sailors. Nossa Senhora da Lapa is a fine 18th-century church, Corinthian in style; São Francisco is a Gothic basilica dating from 1410; Nossa Senhora da Serra do Pilar is a secularized Augustinian convent used as artillery barracks, and marks the spot at which Wellington forced the passage of the Douro in 1809. The exchange (lonja) is another secularized convent, decorated with coloured marbles. Parts of the interior are floored and panelled with polished native-coloured woods from Brazil, which are inlaid in elaborate patterns; there is a very handsome staircase, and the fittings of one large room are an excellent modern copy of Moorish ornamentation.

Other noteworthy public buildings are the museum, library, opera-house, bull-ring, hospital and quarantine station. The crystal palace is a large glass and iron structure built for the industrial exhibition of 1865; its garden commands a fine view of the city and river, and contains a small menagerie. The English factory, built in 1790, has been converted into a club for the British residents—a large and important community whose members are chiefly connected with the wine and shipping trades. Lawn tennis, cricket, boat-racing on the Douro, and other British sports have been successfully introduced, and there is keen competition between the Oporto clubs and those of Lisbon and Carcavellos. The English club gave its name to the Rua Nova dos Inglêses, one of the busiest streets, which contains many banks, warehouses and steamship offices. The

Rua da Alfândega, skirting the right bank of the Douro and passing the custom house (alfândega), is of similar character; here may be seen characteristic types of the fishermen and classes of southern Portugal. The Rua das Flores contains, on its eastern side, the shops of the cloth-dealers; on the west are the jewellers' shops, with a remarkable display of gold and silver filigree-work and enamelled gold. Oporto is famous for these ornaments, which are often very artistic, and are largely worn on holidays by women of the poorer classes, whose savings or dowries are often kept in this readily marketable form.

Oporto is chiefly famous for the export of the wine which bears its name. An act passed on the 29th of January 1906 defined "port" as a wine grown in the Douro district, exported from Oporto, and containing more than 16.5% of alcoholic strength. The wines from which it is made grow in the Paiz do Vinho, a hilly region about 60 m. up the river, and having an area of 27 m. in length by 5 or 6 in breadth, cut off from the sea, and shut in from the north-east by mountains. The trade was established in 1678, but the shipments for some years did not exceed 600 pipes (of 115 gallons each). In 1703 the British government concluded the Methuen treaty with Portugal, under which Portuguese wines were admitted on easier terms than French or German, and henceforward "port" began to be drunk (see WINE: History). In 1747 the export reached 17,000 pipes. In 1754 the great wine monopoly company of Oporto originated, under which the shipments rose to 33,000 pipes. At the beginning of the 19th century the policy of the government more and more favoured port wine, besides which the vintages from 1802 to 1815 were splendid both in Portugal and in Madeira—that of 1815 has, in fact, never been excelled. For the next few years the grape crop was not at all good, but the 1820 vintage was the most remarkable of any. It was singularly sweet and black, besides being equal in quality to that of 1815. This was long regarded as the standard in taste and colour for true port, and to keep up the vintage of following years to this exceptional standard adulteration by elder berries, &c., was resorted to. This practice did not long continue, for it was cheaper to adulterate the best wines with inferior sorts of port wine itself. In 1852 the Oldium which spread over Europe destroyed many of the Portuguese vineyards. In 1865 Phylloxera did much damage, and in 1867 the second monopoly company was abolished. From this time the exports again increased. (See WINE.)

A third of the population is engaged in the manufacture of cottons, woolens, leather, silk, gloves, hats, pottery, corks, tobacco, spirits, beer, acrated waters, preserved foods, soap or distilleries. Oporto is a seaport of world importance, being the headquarters of the chief Portuguese shipping company. Cotton piece goods are sent to the African colonies, and, in small quantities, to Brazil; their value in 1905 was £120,360, but a larger quantity was retained for the home market. The fisheries—chiefly of hake, bream and sardines—are extensive. Steam-trailing, though unsuccessful in the 19th century, was resumed in 1904, and in 1906 there were 136 British, 10 Dutch and 3 Portuguese steamers thus engaged. The innovation was much resented by the owners of more than 350 small sailing boats, and protective legislation was demanded. In 1905 the combined port of Oporto and Leixões was entered by 1734 vessels of 1,562,724 tons, but in this total some vessels were counted twice over—i.e. once at each port. Nearly three-fourths of the tonnage was entered at Leixões. About the close of the 19th century there was an important development of tourist traffic from Liverpool and Southampton via Havre. Reduced railway rates and improved hotel accommodation have facilitated the growth of this traffic. Many tourists land at Oporto and visit Braga (q.v.), Bussaco (q.v.) and other places of interest, on their way to Lisbon. There is also a large tourist traffic from Germany. The exports of Oporto include wine, cottons, wood, pitwood, stone, cork, salt, succahns, onions, olive-oils and beans. American competition has destroyed the export trade in live cattle for which Great Britain was the principal market. Dried codfish (bacalhau) is imported in great quantities from Newfoundland and Norway; other noteworthy imports are
coal, iron, steel, machinery and textiles. The total yearly value of the foreign trade exceeds £5,000,000.

The history of Oporto dates from an early period. Before the Roman invasion, under the name of Portus Cælia, Gaia or Cago, it was a town on the south bank of the Douro with a good trade; the Alani subsequently founded a city on the north bank, calling it Castrum Novum. About A.D. 530 the Visigoths under Leovigild obtained possession, but yielded place in 716 to the Moors. The Christians, however, recaptured Oporto in 997, and it became the capital of the counts of Portugal for part of the period during which the Moors ruled in the southern provinces of Portugal. (See Portugal: History.) The Moors once more became its masters for a short period, till in 1092 it was brought finally under Christian domination. The citizens rebelled in 1628 against an unpopular tax, in 1651 for a similar reason, in 1757 against the wine monopoly, and in 1808 against the French. The town is renowned in British military annals from the duke of Wellington's passage of the Douro, by which he surprised and put to flight the French army under Marshal Soult, capturing the city on the 12th of May 1809. Oporto sustained a severe siege in 1823-1824, being bravely defended against the Migueletes by Dom Pedro with 7,000 soldiers; 16,900 of its inhabitants perished. In the constitutional crises of 1820, 1826, 1836, 1842, 1846-1847, 1851 and 1907-1908 the action of Oporto, as the capital of northern Portugal, was always of the utmost importance.

Opossum, an American Indian name properly belonging to the American marsupials (other than Caenolestes), but in Australia applied to the phalangers (see Phalanger). True opossums are found throughout the greater part of America from the United States to Patagonia, the number of species being largest in the more tropical parts (see Marsupialia). They form the family Didelphidae, distinguished from other marsupial families by the equally developed hind-toes, the nailless but fully opposable first hind-toe, and by the dentition, of which the formula is i. 1, c. 1, p. 1, m. 3; total 50. The peculiarity in the mode of succession of these teeth is explained in the article referred to. Opossums are small animals, varying in size from the size of a mouse to that of a large cat, with long noses, ears and tails, the latter being as a rule naked and prehensile, and with the first toe in the hind-foot so fully opposable to the other digits as to constitute a functionally perfect posterior "hand." These opposable first toes are without nail or claw, but their tips are expanded into broad flat pads, which are of great use to these climbing animals. On the anterior limbs all the five digits are provided with long sharp claws, and the first toe is but little opposable. The numerous cheek-teeth are crowned with minute sharply-pointed cusps, with which to crush the insects on which these creatures feed, for the opossums seem to take in South America the place in the economy of nature filled in other countries by hedgehogs, moles, shrews, &c. The true opossums are typically represented by Didelphys marsupialis, a species, with several local races, ranging over the greater part of North America (except the Artic north). It is of large build and extremely common in the United States, where it acts as a scavenger by night, retreating for shelter by day upon the roofs of houses or into the sewers. It produces in the spring from six to sixteen young ones, which are placed by the mother in her pouch immediately after birth, and remain there until able to take care of themselves; the period of gestation being from fourteen to seventeen days. A local race found in Central and tropical South America is known as the crab-eating opossum (D. marsupialis cancivora). The second sub-genus, or genus, Metachirus contains a considerable number of species found all over the tropical parts of the New World. They are of medium size, with short, close fur, very long, scaly and naked tails, and have less developed ridges on their skulls. They have, as a rule, no pouch in which to carry their young, and the latter therefore commonly ride on their mother's back, holding on by winding their prehensile tails round hers, as in the figure of the wooly opossum. The latter belongs to the sub-genus Philander, which is nearly allied to the last; its full title being Didelphys (Philander) lanigerus. The philanderer (D. [P.] philander) is closely related.

The fourth sub-genus (or genus) is Marmosa (Micoureus, or Grymaeomys), differing from the two last by the smaller size of its members and by certain slight differences in the shape of their teeth. Its best-known species is the murine opossum (D. murinus), no larger than a mouse, of a bright-red colour, found as far north as central Mexico, and extending thence to the south of Brazil. A second well-known species is D. cinerea, which ranges from Central America to western Brazil, Peru and Bolivia. Yet another group (Peramys) is represented by numerous shrew-like species, of very small size, with short, hairy and non-prehensile tails, not half the length of the trunk, and unridged skulls. The most striking member of the group is the Three-striped Opossum (D. americana) from Brazil, which is of a reddish grey colour, with three clearly-defined deep-black bands down its back, as in some of the striped mice of Africa. D. dimidis, D. nudiocauda, D. domestica, D. unistrigata and several other South American species belong to this group. Lastly we have the Chiloé Island opossum (D. giroideus), alone representing the sub-genus Dromiciops, which is mostly allied to Marmosa, but differs from all other opossums by the short furry ears, thick hairy tail, doubly swollen auditory bulla, short canines and peculiarly formed and situated incisors.

Whatever difference of opinion there may be as to the right of the above-mentioned groups to generic separation from the typical Didelphys, there can be none as to the distinctness of the water-opossum (Chironectes minimus), which differs from all the other members of the family by its fully webbed feet, and the dark-brown transverse bands across the body (see Water-Opossum). See O. Thomas, Catalogue of Marsupials and Monstrematata (British Museum, 1888), "On Micoureus griseus, with the Description of a New Genus and Species of Didelphidae," Ann. Mag. Nat. Hist. ser. 6, vol. xiv. p. 184; and later papers in the same and other series.

OPPEL, CARL ALBERT (1831-1885), German palaeontologist, was born at Hohenheim in Württemberg, on the 19th of December 1831. After studying mineralogy and geology at Stuttgart, he entered the university of Tübingen, where he graduated Ph.D. in 1853. Here he came under the influence of Quenstedt and devoted his special attention to the fossils of the Jurassic system. With this object he examined in detail during 1854 and the following year the succession of strata in England, France and Germany and determined the various palaeontological stages or zones characterized by special guide-fossils, in most cases ammonites. The results of his researches were published in his great work Die Juraf ormation Englands, Frankreichs und des südwestlichen Deutschlands (1856-1858). In 1858 he became an assistant in the Palaeontological Museum at Munich. In 1860 he became professor of palaeontology in the university at Munich, and in 1861 director of the Palaeontological Collection. There he continued his labours on the Jurassic fauna, describing new species of crustacea, ammonites, &c. To him also we owe...
the establishment of the Tithonian stage, for strata (mainly equivalent to the English Portland and Purbeck beds) that occur on the borders of Jurassic and Cretaceous. Of his later works the most important was Paläontologische Mittheilungen aus dem Museum des Königt. Bayer. Staats. (1862–1865). He died at Munich on the 23rd of December 1865.

OPPELN (Polish, Oppolje), a town of Germany, in the Prussian province of Silesia, lies on the right bank of the Oder, 51 m. S.E. of Breslau, on the railway to Kattowitz, and at the junction of lines to Beuthen, Neisse and Tarnowitz. Pop. (1905) 30,750. It is the seat of the provincial administration of Upper Silesia, and contains the oldest Christian church in the district, that of St Adalbert, founded at the close of the 10th century. It has two other churches and a ducal 15th-century palace on an island in the Oder. The most prominent among the other buildings are the offices of the district authorities, the town hall, the normal seminary and the hospital of St Adalbert. The Roman Catholic gymnasium is established in an old Jesuit college. The industries of Oppeln include the manufacture of Portland cement, machinery, beer, soap, cigars and lime; trade is carried on by rail and river in cattle, grain and the vast mineral output of the district, of which Oppeln is the chief centre. The upper Ashley, which flows into the lower Polish.

Oppeln was a flourishing place at the beginning of the 11th century, and became a town in 1228. It was the capital of the duchy of Oppeln and the residence of the duke from 1163 to 1532, when the ruling family became extinct. Then it passed to Austria, and with the rest of Silesia was ceded to Prussia in 1742.

See Idzikowski, Geschichte der Stadt Oppeln (Oppeln, 1885); and Vogt, Oppeln beim Eintritt in das Jahr 1900 (Oppeln, 1900).

OPPENHEIM, a town of Germany, in the grand duchy of Hesse, picturesquely situated on the slope of vine-clad hills, on the left bank of the Rhine, 20 m. S. of Mainz, on the railway to Worms. Pop. (1905) 3966. The only relic of its former importance is the Evangelical church of St Catherine, one of the most beautiful Gothic edifices of the 13th and 14th centuries in Germany, and recently restored at the public expense. The town has a Roman Catholic church, several schools and memorial of the War of 1870–1. Its industries and commerce are principally connected with the manufacture and export of wine. Above the town are the ruins of the fortress of Landskron, built in the 11th century and destroyed in 1869.

Oppenheim, which occupies the site of the Roman Baunonica, was formerly much larger than at present. In 1226 it appears as a free town of the Empire and later as one of the most important members of the Rhenish League. It lost its independence in 1375, when it was given in pledge to the elector palatine of the Rhine. During the Thirty Years' War it was alternately occupied by the Swedes and the Imperialists, and in 1689 it was entirely destroyed by the French.

See W. Franck, Geschichte der ehemaligen Reichsstadt Oppenheim (Darmstadt, 1889).

OPPERT, JULIUS (1825–1905), German Assyriologist, was born at Hamburg, of Jewish parents, on the 9th of July 1825. After studying at Heidelberg, Bonn and Berlin, he graduated at Kiel in 1847, and in the following year went to France, where he was teacher of German at Laval and at Reims. His leisure was given to Oriental studies, in which he had made progress in Germany, and in 1852 he joined Fresnel's archaeological expedition to Mesopotamia. On his return in 1854 he occupied himself in digesting the results of the expedition in so far as they concerned cuneiform inscriptions, and published an important work upon them (Déchiffrement des inscriptions cunéiformes, 1861). In 1857 he was appointed professor of Sanscrit in the school of languages connected with the National Library in Paris, and in this capacity he produced a Sanscrit grammar; but his attention was chiefly given to Assyrian and cognate subjects, and he was especially prominent in establishing the Turanian character of the language originally spoken in Assyria. In 1869 Oppert was appointed professor of Assyrian philology and archaeology at the Collège de France. In 1865 he published a history of Assyria and Chaldaea in the light of the results of the different exploring expeditions. At a period he devoted much attention to the language and antiquities of ancient Media, writing Le Peuple et la langue des Mèdes (1879). He died in Paris on the 21st of August 1905. Oppert was a voluminous writer upon Assyrian mythology and jurisprudence, and other subjects connected with the ancient civilizations of the East. Among his other works may be mentioned: Éléments de la grammaire assyrienne (1868); L'Immortalité de l'âme chez les Chaldéens, (1875); Salomon et ses successeurs (1877); and, with J. Ménant, Doctrines juridiques de l'Assyrie et de la Chaldée (1877).

OPPIAN (Gr. Ὀππιάνος), the name of the authors of two (or three) didactic poems in Greek hexameters, formerly identified, but now generally regarded as two different persons. (1) Oppian of Corycus (or Anabartus) in Cilicia, who flourished in the reign of Marcus Aurelius (emperor A.D. 161–180). According to an anonymous biographer, his father, having incurred the displeasure of Lucius Verus, the colleague of Aurelius, by neglecting to pay his respects to him when he visited the town, was banished to Malta. Oppian, who had accompanied his father into exile, returned to Rome with him, and on the death of Verus, accompanied his father on a visit to Rome. Here he presented his poems to Aurelius, who was so pleased with them that he gave the author a piece of gold for each line, took him into favour and pardoned his father. Oppian subsequently returned to his native country, but died of the plague shortly afterwards, at the early age of thirty. His contemporaries erected a statue in his honour, with an inscription which is still extant, containing a lament for his premature death and a eulogy of his precocious genius. His poem on fishing (Halieutica), of about 1500 lines, dedicated to Aurelius and his son Commodus, is still extant. (2) Oppian of Apamea (or Pella) in Syria. His extant poem on hunting (Cynegetica) is dedicated to the emperor Caracalla, so that it must have been written after 211. It consists of about 2150 lines, and is divided into four books, the last of which seems incomplete. The author evidently knew the Halieutica, and perhaps intended his poem as a supplement. Like his namesake, he shows considerable knowledge of his subject and close observation of nature; but in style and real merit he is inferior to him. His versification also is less correct. The improbability of there having been two poets of the same name, writing on subjects so closely akin and such near contemporaries, may perhaps be explained by assuming that the real name of the author of the Cynegetica was not Oppian, but that he has been confounded with his predecessor. In any case, it seems clear that the two were not identical.

A third poem on bird-catching (Isaetica, from Libės, bird-line), also formerly attributed to an Oppian, is lost; a paraphrase in Greek prose by a certain Euteneus is extant. The author is probably one Dionysius, who is mentioned by Suidas as the author of a treatise on stones (Lithiaca).

The chief modern editions are J. G. Schneider (1776); F. S. Lehrs (1846); U. C. Bussemaker (Scholia, 1849); (Cynegetica) P. Boudreau (1908). The anonymous biography referred to above appears in A. Wattenau's Geschichte des O. (1845). On the subject generally see A. Martin, Études sur la vie et les œuvres d'Oppien de Cilicie (1864); A. Ausfeld, De Oppiano et scriptis suis (1876). There are translations of the Halieutica, 1–3, by B. H. Doughty and Jones (1722), and in French by E. J. Bourquin (1877).

OPPIUS, GAIUS, an intimate friend of Julius Caesar. He managed the dictator's private affairs during his absence from Rome, and, together with L. Cornelius Balbus, exercised considerable influence in the city. According to Suetonius (Caesar, 36), many authorities considered Oppius to have written the histories of the Spanish, African and Alexandrian wars which are printed among the works of Caesar. It is now generally held that he may possibly be the author of the last (although the claims of Hierius are considered stronger), but certainly not of the two first, although Niebuhr confidently assigned the Bellum Africannum to him; the writer of these took an actual part in the wars they described, whereas Oppius was in Rome at the time. He also wrote a life of Caesar and the elder Scipio.
OPTICS, the science of light, regarded as the medium of sight (Gr. ὄψ). Generally the noun is qualified by an adjective so as to delimitate the principal groups of optical phenomena, e.g. geometrical optics, physical optics, meteorological optics, &c. Greek terminology included two adjective forms—τὰ ὀρατά, for all optical phenomena, including vision and the nature of light, and ὅπλων (sc. θεώπλω), for the objective study of light, i.e. the nature of light itself and the theory of vision. See Light and Vision.

OPTION (Lat. opting, choice, choosing, optare, to choose), the action of choosing or thing chosen, choice or power or opportunity of making a choice. The word had a particular meaning in ecclesiastical law, where it was used of a right claimed by an archbishop to select one benefice from the diocese of a newly appointed bishop, the next presentation to which would fall to his archbishop's, patronage. This right was abolished by various statutes in the early part of the 19th century. As a term in stock-exchange operations, "option" is used to express the privilege given to conclude a bargain at some future time at an agreed-upon price (see CALL and STOCK EXCHANGE). The phrase "local option" has been specifically used in politics of the power given to the electorate of a particular district to choose whether licences for the sale of intoxicating liquor should be granted or not. This form of "local option" has been also and more rightly termed "local veto" (see LIQUOR LAWS).

OPUS ('Ορώς), in ancient Greece, the chief city of the Opuntian Locrians; the walls of the town may still be seen on a hill about 6 m. S.E. of the modern Atalante, and about 1 m. from the channel which separates the mainland from Euboea. It is mentioned in the Homeric catalogue among the towns of the Locrians, who were led by Ajax Oileus; and there were called Alantea and an altar at Opus in honour of Ajax. Opus was also the birthplace of Patroclus. Pindar's Ninth Olympian Ode is mainly devoted to the glory and traditions of Opus. Its founder was Opus the son of Zeus and Protopeneia, the daughter of an Elian Opus, or, according to another version, of Deucalion and Pyrrha, and the wife of Locras. The Locrians deserted the Greek side in the Persian Wars; they were among the allies of Sparta in the Peloponnesian War. In the struggle between Philip V. of Macedon and the Romans the town went over to the latter in 197 B.C., but the Acrostyle held out for Philip until his defeat at Cynoscephalae (Livy xxxii. 32). The town suffered from earthquakes, such as that which destroyed the neighbouring Atalante in 1884.

ORACH, or MOUNTAIN SPINACH, known botanically as Atriplex hortensis, a tall-growing, hardy annual, whose leaves, though coarsely flavoured, are used as a substitute for spinach, and to correct the acidity of sorrel. The white and the green are the most desirable varieties. The plant should be grown quickly in rich soil. It may be sown in rows 2 ft. apart, and about the same distance between the rows, about March, and for succession again in June. If needful, water must be freely given, so as to maintain a rapid growth. A variety, A. hortensis var. rubra, commonly called red mountain spinach, is a hardy annual 3 to 4 ft. high with fine ornamental foliage.

ORACLE (Lat. oraculum, from orārē, to pray; the corresponding Greek word is μαρτυρίον or χορήστρων), a special place where a deity is supposed to give a response, by the mouth of an inspired priest, to the inquiries of his votaries; or the actual response. The whole question of oracles—whether in the sense of the response or the sacred place—is bound up with that of magic, divination and omens, to the articles on which the reader is referred. They are commonly found in the earlier stages of religious culture among different nations. But it is as an ancient Greek institution that they are most interesting historically.

A characteristic feature of Greek religion which distinguishes it from many other systems of advanced cult was the wide prevalence of a ritual of divination and the prominence of certain oracular centres which were supposed to give voice to the will of Providence. A account of the oracles of Greece is concerned with the historical question about their growth, influence and career. But it is convenient to consider first the anthropological question, as to the methods of divination practised in ancient Greece, their significance and the original ideas that inspired them. Only the slightest theoretical construction is possible here; and the true psychologic explanation of the mantic facts is of very recent discovery. In the Greek world these were of great variety, but nearly all the methods of divination found there can be traced among other communities, primitive and advanced, ancient and modern. The most obvious and useful classification of them is that of which Plato is the author, who distinguishes between (a) the "sane" form of divination and (b) the ecstatic, enthusiastic or "insane" form. The first method appears to be cool and scientific, the diviner (μάρτυρ) interpreting certain signs according to fixed principles of interpretation. The second is worked by the prophet, shaman or Pythons, who is possessed and overpowered by the deity, and in temporary frenzy utters mystic speech under divine suggestion. The oracle may adopt the form of a divination with the spiritual words in dreams or through intercourse with the departed spirit; this resembles class (a) in that it does not necessarily involve ecstasy, and class (b) in that it assumes immediate rapport with some spiritual power.

It will be convenient first to give typical examples of these various processes of discovering the divine will, and then to sketch the history of Delphi, the leading centre of divination. We may subdivide the methods that fall under class (a), those that conform to the "omen"-system, according to which they deal with the phenomena of the animate or the inanimate world; although this distinction would not be relevant in the period of primitive animistic thought. The Homeric poems attest that auguries from the flight and actions of birds were commonly observed in the earliest Hellenic period as they occasionally were in the later, but we have little evidence that this method was ever organized as it was at Rome into a regular system of state-divination, still less of state-craft. We can only quote the passage in the Antigone where Sophocles describes the method of Teiresias, who keeps an aviary where he studies and interprets the flight and the cries of the birds; it is probable that the poet was aware of some such practice actually in vogue. But the usual examples of Greek augury do not suggest deliberate and systematic observation; for instance, the phenomenon in the Iliad of the eagle seizing the snake and dropping it, or, in the Agamemnon of Aeschylus, of the eagles swooping on the pregnant hare. Other animals besides birds could furnish omens; we have an interesting story of the omen derived from the contest between a wolf and a bull which decided the question of the sovereignty of Argos when Danaus arrived and claimed the kingdom; and the private superstitious man might be encouraged or depressed by any ominous sign derived from any part of the animal world. But it is very rare to find such omens habitually consulted in any public system of divination sanctioned by the state. We hear of a shrine of Apollo at Sura in Lycia, where omens were taken from the movements of the sacred fire that were kept there in a tank; and again of a grove consecrated to this god in Sporus, where tame serpent were kept and fed by a priestess, who could predict a good or bad harvest according as they ate heartily or came willingly to her or not.

But the method of animal divination that was most in vogue was the inspection of the inward parts of the victim offered upon the altar, and the interpretation of certain marks found there according to a conventional code. Sophocles in the passage referred to above gives us a glimpse of the prophet's procedure. A conspicuous example of an oracle organized on this principle was that of Zeus at Olympia, where soothsayers of the family of the Iamidai prophesied partly by the inspection of entrails.
partly by the observation of certain signs in the skin when it was cut or burned. Another less familiar procedure that belongs to this subdivision is that which was known as divination διὰ κληρονομία, which might sometimes have been the cries of birds, but in an oracle of Hermes at the Achaean city of Pharsa were the casual utterances of men. Pausanias tells us how this was worked. The consultant came in the evening to the statue of Hermes in the market-place that stood by the side of a heath-altar to which bronze lamps were attached; having kindled the lamps and put a piece of money on the altar, he whispered into the ear of the statue what he wished to know; he then departed, closing his ears with his hands, and whatever human speech he first heard after withdrawing his hands he took for a sign. The same custom seems to have prevailed at Thebes in a shrine of Apollo, and in the Olympic oracle of Zeus.

Of omens taken from what we call the inanimate world salient examples are those derived from trees and water, a distinction to be explained by an animistic feeling that may be regarded as at one time universal. Both were in vogue at Dodona, where the ecstatic method of prophecy was never used; we hear of divination there from the bubbling stream, and still more often of the "talking oak"; under its branches may once have slept the Selloi, who interpreted the sounds of the boughs, and who may be regarded as the depositaries of the Aryan tradition of Zeus, the oak god who spoke in the tree. At Korope in Thessaly we hear vaguely of an Apolloine divination by means of a branch of the tamarisk tree, a method akin no doubt to that of the divining rod which was used in Greece elsewhere; and there is a late record that at Daphne near Antioch oracles were obtained by dipping a laurel leaf or branch in a sacred stream. Water divination must have been as familiar at one time to the Greeks as it was to the ancient Germans; for we hear of the fountain at Daphne revealing things to come by the varying murmur of its flow; and marvellous reflections of a manish import might be seen in a spring on Taenaron in Laconia; another at Patrae omens were drawn concerning the chances of recovery from disease. Thunder magic, which was practised in Arcadia, is usually associated with thunder divination; but of this, which was so much in vogue in Etruria and was adopted as a state-craft by Rome, the evidence in Greece is singularly slight. Once a year watchers took their stand on the wall at Athens and waited till they saw the lightning flash from Harmia, which was accepted as an auspicious omen for the setting out of the sacred procession to Apollo Pythius at Delphi; and the altar of Zeus Σπαλειος, the sender of omens, on Mount Parnes, may have been a religious observatory of meteorological phenomena.

No doubt such a rare and portentous event as the fall of a meteorite would be regarded as ominous, and the state would be inclined to consult Delphi or Dodona as to its divine import.

We may conclude the examples of this main department of μαντική by mentioning a method that seems to have been much in vogue in the earlier times, that which was called διὰ γυμνωμον μαντικ, or divination by the drawing or throwing of lots; these must have been objects, such as small pieces of wood or dice, with certain marks inscribed upon them, drawn casually or thrown down and interpreted according to a certain code. This simple process of immemorial antiquity, for other Aryan peoples such as the Teutonic possessed it, was practised at Delphi and Dodona by the side of the more solemn procedure; we hear of it also in the oracle of Heracles at Bura in Achaia. It is this method of "scraping" or "notching" (πτετεία) signs on wood that explains probably the origin of the words χωρομαθής, χωρομαθής, ἀποσυρίσας for oracular consultation and delivery.

The processes described are a part of a world-wide system of popular divination. And most of them were taken up by the oracular shrines in Greece, Apollo himself having no special and characteristic mantic method, but generally adopting that which was of local currency. But much that is adopted by the higher personal religions descends from a more primitive and lower stage of religious feeling. And all this divination was originally independent of any personal divinity. The primitive diviner appealed directly to that mysterious potency which was supposed to inhere in the tree and spring, in the bird or beast, or even in a notched piece of wood. At a later stage, it may be, this power is interpreted in accordance with the animistic, and finally with the theistic, belief; and now it is the god who sends the sign, and the bird or animal is merely his organ. Hence the omen-seeker comes to prefer the sacrificed animal, as likely to be in touch with the divine spirit through contact with the altar. And, again, if we are to understand the most primitive thought, we probably ought to conceive of it as regarding the omen not as a mere sign, but in some confused sense as a cause of that which is to happen. By sympathetic magic the flight of the bird, or the appearance of the entrails, is mysteriously connected, as cause with effect, with the event which is desired or dreaded. Thus in the Aztec sacrifice of children to procure rain, the victims were encouraged to shed tears copiously; and this was a mere sign of an abundant rainfall, but was sympathetically connected with it. And in the same way, when of the three beasts over which three kings swore an oath of alliance, one died prematurely and was supposed thereby to portend the death of one of the kings, or when in the Lacedaemonian sacrifice the head of the victim mysteriously vanished, and this portended the death of their naval commander, these omens would be merely signs of the future for the comparatively advanced Hellene; but we may discern at this stage that there was still, that these things were somehow casually or sympathetically connected with the kindred events that followed. We can observe the logical nexus here, which in most instances escapes us. This form of divination, then, we may regard as a special branch of sympathetic magic, which nature herself performs for early man, and which it concerns him to watch.

The other branch of the mantic art, the ecstatic or inspired, has had the greater career among the peoples of the higher religions; and morphologically we may call it the more advanced, as Shamanism or demoniac or divine possession implies the belief in spirits or divinities. But actually it is no doubt of great antiquity, and it is found still existing at a rather low grade of savagery. Therefore it is unsafe to infer from Homer’s silence about it that it only became prevalent in Greece in the post-Homeric period. It did not altogether supersede the simpler method of divination by omens; but being far more impressive and awe-inspiring, it was adopted by some of the chief Apolloic oracles, though never by Dodona.

The most salient example of it is afforded by Delphi. In the historic period, and perhaps from the earliest times, a woman known as the Pythia was the organ of inspiration, and it was generally believed that she delivered her oracles under the direct afflatus of the god. The divine possession worked like an epileptic seizure, and was exhausting and might be dangerous; nor is there any reason to suppose that it was simulated. This communion with the divinity needed careful preparation. Originally, as it seems, virginity was a condition of the tenure of the office; for the virgin has been often supposed to be the purer vehicle for divine communication; but later the rule was established that a married woman over fifty years of age should be chosen, with the proviso that she should have had no child. As a preliminary to the divine possession, she appears to have chewed leaves of the sacred laurel, and then to have drunk water from the prophetic stream called Kassotis which flowed underground. But the culminating point of the afflatus was reached when she seated herself upon the tripod; and here, according to the belief

15 Plut. Vita Pyrrh. c. 6.
16 Diod. Sic. xiii. 97.
of at least the later ages of paganism, she was supposed to be inspired by a mystic vapour that arose from a fissure in the ground. Against the ordinary explanation of this as a real mephitic gas pro-lucencing convulsions, there seem to be geological and chemical objections;\(^1\) nor have the recent French excavations revealed any chasm or gap in the floor of the temple. But the strong testimony of the later writers, especially Plutarch,\(^2\) cannot wholly be set aside; and we can sufficiently reconcile it with the facts if we suppose a small crack in the floor through which a draught of air was felt to ascend. This, combining with the other mantic stimulants used, would be enough to throw a believing medium into a condition of mental seizure; and the difficulty felt by the older generation of scholars, who had to resort to the hypothesis of charlatanism or diabolic agency, no longer exists in the light of modern anthropology and the modern science of psychic phenomena. The Pythiosis was no ambiguous pretender, but ordinarily a virtuous woman of the lower class. It is probable that what she uttered were only unintelligible murmurs, and that these were interpreted into relevance and set in metric or prose sentences by the "prophet" and the "Holy Ones."\(^3\) or ""οὔσι as they were called, members of leading Delphic families, who sat round the tripod, who received the questions of the consultant beforehand, probably in writing, and usually had considered the answers that should be given.

Examples of the same enthusiastic method can be found in other oracles of Apollo. At Argos, the prophetess of the Apollo Pythios attained to the divine afflatus by drinking the blood of the lamb that was sacrificed in the night to him;\(^4\) this is obviously a mantic communion, for the sacrificial victim is full of the spirit of the divinity. And we find the same process at the prophetic shrine of Ge at Aegae in Achaea, where the prophetess drank a draught of bull's blood for the same purpose.\(^5\) In the famous oracle shrines of Apollo across the sea, at Klaros and Branchides near Miletus, the divination was of the same ecstatic type, but produced by a simple draught of holy water. The Clarion prophet fasted several days and nights in retirement and stimulated his ecstasy by drinking from a subterranean spring which is said by Pliny to have shortened the lives of those who used it.\(^6\) Then, on certain fixed nights after many sacrifices had been offered, he delivered his oracles, shrouded from the eyes of the consultants.\(^7\)

The divination by "incubation" was allied to this type, because though lacking the ecstatic character, the consultant received direct communion with the god or departed spirit. He attained it by laying himself down to sleep or to await a vision, usually by night, in some holy place, having prepared himself by a course of ritualistic purification. Such consultation was naturally confined to the underworld divinities or to the departed heroes. It appears to have prevailed at Delphi when Ge gave oracles there before the coming of Apollo, and among the heroes Amphaius, Calchas and Triphono are recorded to have communicated with their worshippers in this fashion. And it was by incubation that the sick and diseased who repaired to the temple of Epiphanus received their prescriptions from Asclepius, originally a god of the lower world.

After this brief account of the prevalent forms of prophetic consultation, it remains to consider the part played by the Greek oracles in the history of Greek civilization. It will be sufficient to confine our attention to Delphi, about which our information is immeasurably fuller than it is about the other shrines. In the earliest period Dodona may have had the higher prestige, but after the Homeric age it was eclipsed by Delphi, being consulted chiefly by the western Greeks, and occasionally in the 4th century by Athens.

The gorgel of Delphi was a seat of prophecy from the earliest days of Greek tradition. Ge, Themis, and perhaps Poseidon had given oracles here before Apollo. But it is clear that he had won it in the days before Homer, who attests the prestige and wealth of his Pythia shrine; and it seems clear that before the Dorian conquest of the Peloponnesian Dryopian migration had already carried the cult of Apollo Pythius to Asine in Argolis. Also the constitution of the Amphictyonies, "the dwellers around the temple," reflects the early age when the tribe rather than the city was the political unit, and the Dorian were a small tribe of north Greece. The original function of these Amphictyonies was to preserve the sanctity and property of the temple; but this common interest early developed a certain rule of intertribal morality. By the formula of the Amphictyonic oath preserved by Aeschines, which may be of great antiquity, the members bound themselves "not to destroy any city of the league, not to cut any one of them off from spring-water, either in war or peace, and to war against any who violated these rules." We discern here that Greek religion offered the ideal of a federal national union that Greek politics refused to realize.

The next stage in the history of the oracle is presented by the legend of the Dorian migration. For we have no right to reject the strong tradition of the Delphic encouragement of this movement, which well accounts for the devotion shown by Sparta to the Pythian god from the earliest days; and accounts also for the higher position that Delphi occupied at the time when Greek history is supposed to begin.

We have next to consider a valuable record that belongs to the end of the 8th century or beginning of the 7th, the Homeric hymn to Apollo, which describes the coming of the Dolphin-God—Δελφίνος—to Pytho, and the organization of the oracle by Cretan ministers. Of this Cretan settlement at Delphi there is no other literary evidence, and the ""οὔσι who administered the oracle in the historic period claimed to be of aboriginal descent. Yet recent excavation has proved a connexion between Crete and Delphi in the Minoan period; and there is reason to believe that in the 8th century some ritual of purification, momentous for the religious fervor of the oracle, was brought from Crete to Delphi, and that the adoption of this latter name for the place which had formerly been called Πυθὼ synchronized with the coming of Apollo Delphinus.

The influence of Delphi was great in various ways, though no scholar would now maintain the exaggerated dogma of Curtius, who imputed to the oracle a lofty religious enthusiasm and the consciousness of a religious political mission.

We may first consider its political influence upon the other states. The practice of a community consulting an oracle on important occasions undoubtedly puts a powerful weapon into the hands of the priesthood, and might lead to something like a theocracy. And there are one or two ominous hints in the Odyssey that the ruler of the oracle might overthrow the ruler of the land. Yet owing to the healthy temperament of the early Greek, the civic character of the priesthood, the strength of the autocracy, and the fact that the oracle never exposed itself to the peril of popular control, the Delphic priesthood, content with their rich revenues, were probably never tempted to enter upon schemes of far-reaching political ambition, nor were they in any way fitted to be the leaders of a national policy. Once only, when the Spartan state applied to Delphi to sanction their attack on Arcadia, did the oracle speak as if, like the older papacy, it claimed to dispose of territory—""Thou askest of me Arcadia; I will not give it thee." But here the oracle is on the side of righteousness, and it is the Spartan that is the aggressor. In the various oracles that have come down to us, many of which must have been genuine and preserved in the archives of the state that received them, we cannot discover any marked political policy consistently pursued by the ""Holy Ones"" of Delphi. As conservative aristocrats they would probably dislike tyranny; their action against the Peisistratidate was interested, but one oracle contains a spirited rebuke to Cleisthenes, while one or two others, perhaps not genuine, express the spirit of temperate constitutionalism. As exponents of an
Amphictyonic system they would be sufficiently sensitive of the moral conscience of Greece to utter nothing in flagrant violation of the “jus gentium.” In one department of politics, the legislative sphere, it has been supposed that the influence of Delphi was direct and inspiring. Plato and later writers imagined that the Pythons had dictated the Lycurgean system, and even modern scholars like Bergk have regarded the ἱππατος of Sparta as of Delphic origin. But a severer criticism dispels these suppositions. The Delphic priesthood had neither the capacity nor probably the desire to undertake so delicate a task as the drafting of a code. They might make now and again a general suggestion when consulted, and, availing themselves of their unique opportunities of collecting foreign intelligence, they might often recommend a skilful legislator or arbitrator to a state that consulted them at a time of intestine trouble. Finally, a legislator with a code would be well advised, especially at Sparta, in endeavouring to obtain the sanction and the blessing of the Delphic god, that he might appear before his own people as one possessed of a religious mandate. In this sense we can understand the stories about Lycurgus.

There is only one department of the secular history of Greece which is predominant and most effective part, the colonial department. The great colonial expansion of Greece, which has left so deep an imprint on the culture of Europe, was in part inspired and directed by the oracle. For the proof of this we have not only the evidence of the χρησμοι preserved by Herodotus and others, such as those concerning the foundation of Cyrene, but also the worship of Apollo Ἀρχαγγέλος, “the Founder," prevalent in Sicily and Magna Graecia, and the early custom of the sending of tithes or thanksgiving offerings by the flourishing western states to the oracle that had encouraged their settlements.

Apollo was already a god of ways—Ἄγγεις—who led the migration of tribes before he came to Delphi. And those legends are of some value that explain the prehistoric origin of cities such as Magnesia on the Maeander, the Dryopian Asine in the Peloponnesse, as due to the colonization of temple-slaves, acquired by the Pythian god as the title of conquests, and planted out by him in distant settlements. The success of the oracle in this activity led at last to the establishment of the rule that Herodotus declares to be almost universal in Greece, namely, that no leader of a colony would start without consulting Delphi. Doubtless in many cases the priesthood only gave encouragement to a pre-conceived project. But they were in a unique position for giving direct advice also, and they appear to have used their opportunities with great intelligence.

Their influence on the state cults can be briefly indicated, for it was not by any means far-reaching. They could have felt conscious of no mission to preach Apollo, for his cult was an ancient heritage of the Hellenic stocks. Only the narrower duty devolved upon them of impressing upon the commentators the religious obligation of sending tithes or other offerings. Nevertheless their opportunity of directing the religious and organization of the public worship was great; for Plato’s view that all questions of detail in religion should be left to the decision of the god “who sits on the omphalos” was on the whole in accord with the usual practice of Greece. Such consultations would occur when the state was in some trouble, which would be likely to be imputed to some neglect of religion, and the question to the oracle would commonly be put in this way—”what god or goddess or hero shall we sacrifice?” The oracle would then be inclined to suggest the name of some divine personage hitherto neglected, or of one of whose rites had fallen into decay. Again, Apollo would know the wishes of the other divinities, who were not in the habit of directly communicating with their worshippers; therefore questions about the sacred land of the goddesses at Eleusis would be naturally referred to him. From both these points of view we can understand why Delphi appears to have encouraged the tendency towards hero-worship which was becoming rife in Greece from the 7th century onwards. But the only high cult for which we can discover a definite enthusiasm in the Delphic priesthood was that of Dionysus. And his position at Delphi, where he became the brother-deity of Apollo, sufficiently explains this.

As regards the development of religious morality in Greece, we must reckon seriously with the part played by the oracle. The larger number of deliverances that have come down to us bearing on this point are probably spurious, in the sense that the Pythia did not actually utter them, but they have a certain value as showing the ideas entertained by the cultivated Hellene concerning the oracular god. On the whole, we discern that the moral influence of Delphi was beneficent and on the side of righteousness. It did nothing, indeed, to abolish, it may even have encouraged at times, the barbarous practice of human sacrifice, which was becoming abhorrent to the Greek of the 6th and 5th centuries; but a conservative priesthood is always liable to lag behind the moral progress of an age in respect of certain rites, and in other respects it appears that the “Holy Ones” of Delphi kept well abreast of the Hellenic advance in ethical thought. An oracle attributed to the Pythons by Theopompus (Porphy. De abstin. 2, 16 and 17) expresses the sentiment in the story of “the widow’s mite,” that the deity prefers the humble offering of the righteous poor to the costly and pompous sacrifice of the rich. Another, of which the authenticity is vouched for by Herodotus (vi. 80), denounces the contemplated perjury and fraud of a certain Glauclus, and declares to the terrified sinner that to tempt God was no less a sin than to commit the actual crime. A later χρησμός, for which Plutarch (de Pyth. Or. p. 404 B) is the authority, embodies the charitable conception of forgiveness for venal faults committed under excessive stress of temptation: “God pardons what man’s nature is too weak to resist.” And in one most important branch of morality, with which progressive ancient law was intimately concerned, namely, the concept of the sin of homicide, we have reason for believing that the Apolline oracle played a leading part. Perhaps so early as the 8th century, it came to lay stress on the impurity of bloodshed and to organize and impose a ritual of purification; and thus to assist the development and the clearer definition of the concept of murder as a sin and the growth of a theory of equity which recognizes extenuating or justifying circumstances. 3 Gradually, as Greek ethics escaped the bondage of ritual and evolved the idea of spiritual purity of conscience, this found eloquent expression in the utterances imputed to the Pythons. 4 Many of these are no doubt literary fictions; but even these are of value as showing the popular view about the oracular god, whose temple and tripod were regarded as the shrine and organ of the best wisdom and morality of Greece. The downfall of Greek liberty before Macedon destroyed the political influence of the Delphic oracle; but for some centuries after it still retained a certain value for the individual as a counsellor and director of private conscience. But in the latter days of paganism it was eclipsed by the oracles of Claros and Branchidae.

ANCIENT AUTHORITIES.—Plutarch, De Pytho Oraculo et De Scripta oraculorum; Cicero, De Divinatione; Eusebius, Praep. xviii. c. 4 (L. R. F.)

ORAKZAI, a Pathan tribe on the Kohat border of the North-West Frontier Province of India. The Orakzais inhabit the mountains to the north-west of Kohat district, bounded on the N. and E. by the Afridis, on the S. by the Miranzei valley and on the W. by the Zai-mukt country and the Safed Koh mountains. Their name means “lost tribes,” and their origin is buried in obscurity; though they resemble the Afghans in language, features and many of their customs, they are rejected by them as brethren. One branch, the Ali Khel, has been traced to Swat, whence they were expelled by the other inhabitants,
and it is not improbable that the whole tribe consists of refugee clans of the surrounding races. They are very wiry-looking mountaineers, but they are not as fine men or as brave fighters as their neighbours the Afridis. They cultivate a good deal of the Khand and Kurkuma valleys in the winter, but in the hot months retire to the heights of Tirah, of which they occupy the southern half called the Mastura valley. They have been estimated at 28,000 fighting men, but this estimate must be largely exaggerated, as the country could not possibly support the consequent population of over 100,000. They have been the object of various British military expeditions, notably in 1855, 1868, 1890, 1891, and the Tirah campaign of 1897.

ORAN (Arabic Wahrān, i.e. ravine), a city of Algeria, capital of the department and military division of the same name. It stands at the head of the Gulf of Oran, on the Mediterranean in 35° 44' N., 6° 41' W. The city is 261 m. by rail W.S.W. of Algiers, 220 m. E. of Gibraltar and 130 m. S. of Cartagena, Spain. It is built on the steep slopes of the Jebel Murjajo, which rises to a height of 1900 ft. The city was originally cut in two by the ravine of Wad Rekhi, but has been rebuilt and is now the most part covered by boulevards and buildings. West of the ravine lies the old part of the city, known as the Spanish town, with the ancient citadel looking down on it; but few traces of Spanish occupation remain. The modern quarter rises, like an amphitheatre, to the east of the ravine. The place d'Armes, built on the plateau above the ravine, is the centre of the modern quarter. It contains a fine column commemorative of the battle of Sidi Brahim (1845), between the French and Abd-el-Kader. The Château Neuf, built in 1563 by the Spaniards, overlooks the old port. Formerly the seat of the beys of Oran, it is occupied by the general in command of the military division and also serves as barracks. The kasbah (cited) or Château Vieux, used for military purposes, lies S.W. of the Château Neuf. It was partly destroyed by the earthquake of the 8th and 9th of October 1790. On the hills behind the kasbah are Fort St Grégoire, a votive chapel commemorative of the cholera of 1849, and Fort Santa Cruz, crowning at a height of 1312 ft. the summit of the Aïdar. Fort de la Moune (so called from the monks said to have haunted the neighbourhood) is at the western end of the harbour, and commands the road from Oran to Mers-el-Kebir (see below). Fort St Philippe, south of the kasbah, replaces the old Castle of the Saints of the Spaniards. There is subterranean communication between all the ancient forts. The cathedral, dedicated to St Louis, and built in 1839, occupies the site of a chapel belonging in the days of Spanish dominion to a convent of monks of St Bernard. The Grand Mosque (in rue Philippe) was erected at the end of the 18th century to commemorate the expulsion of the Spaniards, and with money paid as ransom for Christian slaves. Other mosques have been turned into churches or utilized for military purposes. The military hospital, a large building adjoining the cathedral, contains 1400 beds. A house in the place de l'hôpital, now used by the military, was once the home of the Inquisition; it was built at the expense of Spain in 1772. The museum formed by the Oran Society of Geography and Archaeology (founded in 1878) has a fine collection of antiquities.

Oran is the seat of a large trade. There is regular communication with Marseilles, Cete, Barcelona, Valencia, Cartagena, Malaga, Gibraltar, and the various ports on the Barbary coast. The railway to Algiers is joined at Pérregaux (47 m. E. of Oran) by the line from Arzew to Saïda and Ain Sefra which serves the high plateau whence esparto is obtained. There is also a railway to Sidi-Bel-Abbès and Tlemcen. The export trade is chiefly in esparto grass, cereals, wines, olive oil, marbles, cattle and hides. The imports include manufactured goods, coal and other commodities. The inner harbour, or old port, contains two basins, one of 10 acres and another of 50 acres, formed by the construction of a pier eastward from Fort de la Moune, with two cross piers. In consequence of the growing importance of the port and the decision of the French government to make Oran the chief naval station in Algeria, it was decided to build an eastern harbour. This outer harbour, on which work was begun in 1905, lies east of the old port and is about double its size. The least depth of water in the old harbour is 18 ft., the average depth in the new harbour is 30 ft., the depth at the entrance being 40 ft. The population of the city in 1906 was 110,409, of whom 21,006 were French, and 23,071 Spanish. There were also 27,570 naturalized Frenchmen, mostly of Spanish origin. There is a negro colony in the city, numbering about 3000, included in the census in the native population of 16,266. Including the garrison and naval forces the total population of the commune was 106,517.

Four miles west of Oran a small promontory forms the harbour of Mers-el-Kebir, formerly a stronghold of the Barbary pirates. The promontory is strongly fortified and crosses fire with a battery erected to the east of Oran. A road along the east coast, cut for the most part out of the solid rock, connects Oran and Mers-el-Kebir.

Attempts have been made to identify Oran with the Quiza, and Mers-el-Kebir with the Portus Magnus, of the Romans. There are, however, no Roman ruins at Oran or at Mers-el-Kebir. The foundation of Oran is more properly ascribed to Andalusian Arabs, who settled there in the beginning of the 10th century, gave it its name. Rapidly rising into importance as a seat-port, Oran was taken and retaken, pillaged and rebuilt, by the various conquerors of northern Africa. Almoravides, Almohades and Marinides succeeded each other, and in the space of half a century the city changed hands nine times. In the latter half of the 15th century it became subject to the sultans of Tlemcen, and reached the height of its prosperity. Active commerce was maintained with the Venetians, the Pisans, the Genoese, the Marseillais and the Catalans, who imported the produce of their looms, glass-wares, tin-wares, and iron, and received in return ivory, ostrich feathers, gold-dust, tanned hides, grain and negro slaves. Admirable woollen cloth and splendid arms were manufactured. The magnificence of its mosques and other public buildings, the number of its schools, and the extent of its warehouses shed lustre on the city; but wealth and luxury began to undermine its prosperity, and its ruin was hastened by the conduct of the Moslem refugees from Spain. Under the influence of these refugees the legitimate trade of the town gave place to piracy, Mers-el-Kebir becoming the stronghold of the pirates.

Animated by the patriotic enthusiasm of the Cardinal Ximenes, the Spaniards determined to put a stop to these depredations which were carrying off their countrymen, destroying their commerce, and even ravaging their country. Mers-el-Kebir fell into their hands on the 23rd of October 1505, and Oran in May 1509. The latter victory, obtained with but trifling loss, was stained by the massacre of a third of the Mahomedan population. From 6000 to 8000 prisoners, 60 cannon, engines of war and a considerable booty from the wealth accumulated by piracy fell into the hands of the conquerors. Cardinal Ximenes introduced the Inquisition, &c., and also restored and extended the fortifications. Oran became the penal settlement of Spain, but neither the convicts nor the noblemen in disgrace who were also banished thither seem to have been under rigorous surveillance; contemporary accounts speak of constant fêtes, games and bull-fights. Meanwhile the Turks had become masters of Algeria, and expelled the Spaniards from all their possessions except Oran. The bey of Mascara watched his opportunity, and, at length, in 1508, the weakness of Spain and the treason of the court of Vera Cruz obliged the city to capitulate. The Spaniards recovered possession in 1732, but found the maintenance of the place a burden rather than a benefit, the neighbouring tribes having ceased to deal with the Christians. The earthquake of 1790 furnished an excuse for withdrawing their forces. Commencing by twenty-two separate shocks at brief intervals, the oscillations continued from the 8th of October to the 22nd of November. Houses and fortifications were overthrown and a third of the garrison and a great number of the inhabitants perished. Famine and sickness had begun to aggravate the situation when the bey of Mascara appeared before the town with 30,000 men. By prodigies of energy the Spanish commander held out till August 1791, when the Spanish
government having made terms with the bey of Algiers, he was allowed to set sail for Spain with his guns and ammunition. The bey Mahommed took possession of Orange in March 1792, and made it his residence instead of Mascara. On the fall of Algiers the bey (Hassan) placed himself under the protection of the conquerors, and shortly afterwards removed to the Levant. The French army entered the city on the 4th of January 1831, and took formal possession on the 17th of August. In 1832 a census of the town showed that it had but 3800 inhabitants, of whom more than two-thirds were Jews. Under French rule Orange has regained its ancient commercial activity and has become the second city in Algeria.

**ORANGE, HOUSE OF.** The small principality of Orange, a district now included in the French department of Vaucluse, traces back its history as an independent sovereignty to the time of Charlemagne. William, surnamed le Cornet, who lived towards the end of the 8th century, is said to have been the first prince of Orange, but the succession is only certainly known after the time of Gerald Adhemar (fl. 1080). In 1174 the principality passed by marriage to Bertrand de Baux, and there were nine princes of this line. By the marriage of John of Chalon with Marie de Baux, the house of Chalon succeeded to the sovereignty in 1193. The princes of Orange (1) Jean I., (1247-1263), (2) William VIII., 1263-1284, (3) John II., (1284-1302), (4) Bertrand II., (1302-1315), (5) Philip I., (1315-1334), (6) Philip II., (1334-1342), (7) Philip III., (1342-1350), (8) William IX., (1350-1389), (9) Philip IV., (1389-1418). Philip I. was a great warrior and statesman, who was held in great esteem by the emperor Charles V. For his services in his campaigns the emperor gave him considerable possessions in the Netherlands in 1522, and Francis I. of France, who had occupied Orange, was compelled, when a prisoner in Madrid, to restore it to him. Philip II. had no children, and he was succeeded by his nephew René of Nassau-Chalon, son of Philip's sister Claudia and Henry, count of Nassau, the confidential friend and counsellor of Charles V. He too died without an heir in 1544 at the siege of St. Dizier, having devised all his titles and possessions to his first cousin William, the eldest son of William, count of Nassau-Dillenburg, who was the younger brother of René's father, and had inherited the German possessions of the family.

William of Orange-Nassau was but eleven years old when he succeeded to the principality. He was brought up at the court of Charles V. and became famous in history as William the Silent, the founder of the house of Orange. In 1539 he was succeeded by his eldest son Philip, who had been kidnapped by Philip II. of Spain in his boyhood and brought up at Madrid. This prince never married, and on his death in 1568 his next brother, Maurice, stadtholder in the United Netherlands and one of the greatest generals of his time, became prince of Orange. Maurice died in 1625, also unmarried. Frederick Henry, the son of Louise de Coligny, William's fourth wife, born just before his father's murder, now succeeded to the principedom of Orange and to all his brothers' dignities, posts and property in the Netherlands. Frederick Henry was both a great general and statesman. His only son, William, was married in 1641 to Mary, princess royal of England, he being fifteen and the princess nine years old at that date, and he succeeded to the title of prince of Orange on his father's death in 1647. At the very outset of a promising career he suddenly succumbed to an attack of smallpox on the 6th of November 1650, his son William III. being born a week after his father's death.

A revolution now took place in the system of government in the United Provinces. William resigned the offices of stadtholder and captain-and-admiral-general, held by four successive princes of Orange, were abolished. However, the counter revolution of 1672 called William III. to the head of affairs. At this time Louis XIV. conquered the principality of Orange and the territory was incorporated in France, the title alone being recognized by the treaty of Ryswick. William married his cousin Mary, the eldest daughter of James, duke of York, in 1677. In 1688 he landed in England, expelled his father-in-law, James II., from his throne, and reigned as king of Great Britain and Ireland until his death in 1702. He left no children, and a dispute arose among various claimants to the title of prince of Orange. The king of Prussia claimed it as the descendant of the eldest daughter of Frederick Henry; John William Friso of Nassau-Dietz claimed it as the descendant of John, the brother of William the Silent, and also of the second daughter of Frederick Henry. The result was that at the peace of Utrecht in 1713, the king of Prussia abandoned the principality to the king of France in exchange for compensation elsewhere, and John William Friso gained the barren title and became William IV. prince of Orange. His sons William V. and William VI. succeeded him. William VI. in 1815 became William I. king of the Netherlands.

See Bastet, *Histoire de la ville et de la principauté d'Orange* (Orange 1856).

(G. E.)

**ORANGE, a town of Wellington and Bathurst counties, New South Wales, Australia, 192 m. by rail W.N.W. of Sydney. It lies in a fruit and wheat-growing district, in which gold, copper and silver also abound. It is the centre of trade with the western interior and has a number of flourishing industries. Orange also has a great reputation as a health resort. Its suburb, East Orange, in the county of Bathurst, is a separate municipality. Pop., including East Orange (1901), 6331.**

**ORANGE, a town of south-eastern France, capital of an arrondissement in the department of Vaucluse, 72 m. N. by E. of Avignon, on the railway from Lyons to Marseilles. Pop. (1906) of the town, 6472; of the commune, 10,705. Orange is situated at some distance from the left bank of the Rhone, in the midst of meadows, orchards and mulberry plantations, watered by a stream called the Meyne, and overlooked by the majestic summit of Mount Ventoux, which lies 22 m. to the east. The district is highly fertile, and the town deals largely in fruit, and miller-stalks for brooms, as well as in wool, silk, honey and truffles.**

Orange is interesting mainly from its Roman remains. The triumphal arch is not only far finer than any other in France, but ranks third in size and importance among those still extant in Europe. Measuring 72 ft. in height, 69 ft. in width, and 26 ft. in depth, it is composed of three arches supported by Corinthian columns. On three sides it is well preserved, and displays remarkable variety and elegance in its sculptured decorations. To judge from the traces of an inscription, the arch seems to have been erected in honour of Tiberius, perhaps to commemorate his victory over the Gallic chieftain Sacrovir in A.D. 21. It suffered from being used as a donjon in the middle ages. The site of the theatre, dating from the time of the emperor Hadrian and built against a hill from the summit of which a colossal figure of the Virgin commands the town. The façade, which is 121 ft. high, 340 ft. long and 15 ft. thick, is pierced by three square gates surmounted by a range of blind arches and a double row of projecting corbels, with holes in which the poles of the awning were placed. Of the seats occupied by the spectators, only the lower tiers remain. It was used as an out-work to the fortress built on the hill by Maurice of Nassau in 1622, and destroyed fifty years later by order of Louis XIV., whose troops in 1666 captured the town. Up to the beginning of the 19th century it was filled with hovels and stables; these were subsequently cleared out, and at the end of the century the building was restored, and now serves as a national theatre. In the neighbourhood of the theatre traces have been found of a hippodrome; and statues, bas-reliefs and ruins of an amphitheatre also serve to show the importance of the Roman town. Notre Dame, the old cathedral, originally erected by the prefect of Gaul, was ruined by the Barbarians, rebuilt in the 11th and 12th centuries, and damaged by the Protestants.

The town has a sub-prefecture, a tribunal of first instance, and a communal college among its institutions; and it has tile and mosaic works and flour-mills, and manufactories of boots and shoes and brooms. There is trade in truffles, fruit, wine, &c.

Orange (Aravusio), capital of the Caviari, was in 105 B.C. the scene of the defeat of a Roman army by the Cumbrini and Tretonites. It became after Caesar an important Roman colony. Its ramparts and fine buildings were partly destroyed by the
ORANGE

Alamanni and Visigoths, and partly ruined by the eruptions of the middle ages. Orange was included in the kingdom of Austria, fell into the hands of the Saracens and was recovered by Charlemagne. It became the seat of an independent county in the 11th century. From the 14th century till the Revolution the town had a university. At the latter period the town suffered severely from the excesses of a popular commission.

Councils of Orange.—In 441 a synod of sixteen bishops was held at Orange under the presidency of St Hillary of Arles, which adopted thirty canons touching the reconciliation of penitents and heretics; the ecclesiastical right of asylum, diocesan prelates, of bishops, spiritual privileges of the defective or demoniac, the department of catechumens at worship, and clerical celibacy (forbidding married men to be ordained as deacons, and also to be advanced beyond the sub-deaconate).

In 529 a synod of fifteen bishops, after considering the presidency of Caesarius of Arles, assembled primarily to dedicate a church, the gift of Libertius, the lieutenant of Theodoric, in Gaul, but proved to be one of the most important councils of the 6th century. Caesarius had sought the aid of Rome against semi-Pelagianism, and in response Pope Felix IV. had sent certain capitula concerning grace and free-will, drawn chiefly from the writings of Augustine and Prosper. These to the number of twenty-five the synod subscribed, and adopted a supplementary statement, reaffirming the Augustinian doctrines of corruption, human inability, prevenient grace and baptismal regeneration. Its acts were confirmed by Boniface II. on the 25th of January 530, a date which is open to question.

ORANGE, a city of Essex county, New Jersey, U.S.A., in the N.E. part of the state, about 1/4 m. W. of New York City. Pop. (1890) 18,844, (1900) 24,141, (1910) 26,842. The town, incorporated 1820, and by act of 1865, became a borough. It lies in the neighbourhood of Newark, South Orange and Bloomfield, and is connected with Newark, South Orange and Bloomfield by electric lines. The city lies at the base of the eastern slope of the first Watchung, or Orange, Mountain, and is primarily a residential suburb of New York and Newark; with East Orange, West Orange and South Orange it constitutes virtually a single community, popularly known as “the Oranges.” The city has a good public school system and various private schools, including the Duke-Brown School (for girls) and the Carteret Academy (for boys). Of historical interest is the First Presbyterian Church, erected in 1813, the third structure used by this church organization, whose history dates back to 1718. The value of the factory products of Orange increased from $2,005,688 in 1900 to $6,130,650 in 1905, to 105½%, and the capital invested in manufacturing from $1,130,523 in 1900 to $3,441,183 in 1905, to 153½%. Of the total product-value in 1905, $2,411,614 was the value of felt hats manufactured. Among other manufacturers are beer, pharmaceutical supplies and lawn mowers. The city owns and operates its water-works and electric-lighting plant. Settlements were made in or near the limits of the present city soon after the founding of Newark, in 1666, and, on account of the mountainous ridge in this region, they were generally referred to collectively as “Newark Mountain.” As a disagreement soon arose between the people of Newark and those of the “mountain” on questions of church administration, the latter in 1718 severed their connexion with the church at Newark and formed an independent congregation, the “Mountain Society.” The church, which was known also as The Church of the New Ark Mountains,” was finally Congregational, but has become Presbyterian. In 1820 the earliest reference to the neighbourhood as “Orange Dale,” and two years later it is sometimes referred to as “Orange.” In 1866 the legislature incorporated the township of Orange. Parts of its territory were included in South Orange and Fairmount (now West Orange) in 1861 and 1862 respectively, and in 1863 East Orange was created out of part of Orange. Orange was incorporated as a town in 1866 and was chartered as a city in 1872.

See H. Whittemore, The Founders and Builders of Orange (Newark, 1890); J. H. Condit, Early Records of the Township of Orange (1607-1845) (Orange, 1897); and S. Wickes, History of the Orange Water Company (1866-1890) (Orange, 1891).

ORANGE, the longest river of South Africa, almost traversing the continent from ocean to ocean. It rises in Basutoland, less than 200 m. from the Indian Ocean, and flows west, with wide sweeps south and north, to the Atlantic. It drains, with its tributaries, an area estimated at over 400,000 sq. m., passing through more than twelve degrees of longitude or 750 m. in a straight line from source to mouth. The valley of the river exceeds 1,000 m., and the stream has a length of not less than 1,300 m. Its headstreams are in the highest part of the Drakensberg range, the principal source, the Senku, rising, at an elevation of more than 10,000 ft., on the south face of the Mount aux Sources in 28° 48' E., 28° 50' S. The other headstreams are S.E. of the Senku source, in Champagne Castle, Giant’s Castle and other heights of the Drakensberg. The Giant’s Castle source is not more than 130 m. west of the Indian ocean in a direct line. Rising from the inner slopes of the Mount aux Sources, the river flows southwards, under the name of the Senku, which receives from the north several streams which rise in the Maluti Mountains. Of these the largest are the Semene and Senkunya (little Senku) and the best known the Maletsayanne. The Senku descends with its tributaries 400 m. below a point 350 ft. above sea-level. Increased by the perennial waters of these numerous torrents the Senku makes its way S.W. across the upland valleys between the Maluti and Drakensberg ranges. After a course of some 200 m., the 5th W. corner of the Maluti Mountains, the Senku is suddenly known as the Orange, receives the Makhakeng or Kornet Spruit (90 m.), which rises in Machacha Mountain. The Orange here enters the great inner plateau of South Africa, which at Alwil North, the first bend of any size on the banks of the river, 80 m. above the Makhakeng confluence, has an elevation of 4300 ft. Forty miles lower down the Orange is joined by the first of its large tributaries, the Caledon (230 m.), which, rising on the western side of the Mont du Souef, then runs S.W. to the Makhakeng, the Caledon, being the most southerly of the Orange’s tributaries. Thence the river flows more N.W. through the fertile valley north of the Maluti Mountains. At the confluence the united stream has a width of 350 yards. Thirty miles lower down the Orange reaches, in 28° 40' E., its southernmost point on the continent, at Cape Town. As it approaches Cape Town, the Orange’s single largest headland, of its water by evaporation. In this region, nevertheless, skeleton river systems cover the country north and south. These usually dry sandy beds, which on many maps appear rivers of imposing length, for a few hours of summer rains, this sluiced under the beds of higher streams, are deep and turbulent streams. The northern system consists of the Nosob and its tributaries, the Molopo and the Kuruman. These unite their waters in about 20° 40' E. and 27° S., hence a channel known as the Molopo, and the Bylgam, and through to the Orange. The southern river, which at once 100 m. before the fertile great plains of western Cape Colony, is represented by the Brak and Ongers rivers, and, farther west, by the Zaak and Olifants rivers, which, united as the Hartebeest, reach the Orange about the middle of the mouth of the river. After the wet season and in places, have plenty of water, generally dissipated in vleis, pans and stoors (marshy and lake land).

Between the mouths of the Hartebeest and Molopo, in 28° 35' S., 28° 40' E. and 29° 20' S., 28° 40' E., the ground is that of the Orange, where in a series of canyons and cascades the river drops 400 ft. in 16 m. The Aughrabies or Hundred Falls, as they are called, are divided by ledges, reefs and islets, the last named often assuming fantastic forms. In these and other waterfalls the river, after cascades and openings in the cliffs to the water are rare. These openings are usually the sandy beds of dried-up or intermittent affluents, such as the Bäk, Ham, Houn, Aub or Great Fish, rivers of Great Namaqualand.
north and then south, making a loop of fully 90 m., of which the two ends are but 38 m. apart. Crossing 'the narrow coast plain the river, with a south-westerly sweep, enters the ocean by a single mouth, studded with small islands, in 28° 37' S., 16° 30' E. A large sandbar obstructs the entrance to the river, which is not quite 1 m. wide. The river when in flood, at which time it has a depth of 40 ft., scours a channel through the bar, but the Orange is at all times inaccessible to sea-going vessels. Above the bar it is navigable by small craft for 30 or 40 m. In the neighbourhood of the Vaal confluence, where the river passes through alluvial land, and at some other places, the waters of the Orange are used, and are capable of being much more largely used, for irrigation purposes.

The Hottentots call the Orange the Garib (great water), corrupted by the Dutch into Gariep. The early Dutch settlers called it, more properly Groote-Rivier. It was first visited by Europeans about the beginning of the 18th century. In 1654 Simon van der Stelt, then governor of the Cape, led an expedition into Little Namaqualand and discovered the Koper Berg. In 1704 and 1705 other expeditions to Namaqualand were made. Attempts to mine the copper followed, and the prospectors and hunters who penetrated northward sent to the Cape reports of the existence of a great river whose waters always flowed. The first scientific expedition to reach the Orange was that under Captain Henry Hop sent by Governor Tulbagh in 1761, partly to investigate the reports concerning a semi-civilized yellow race living north of the great river. Hop crossed the Orange in September 1761, but shortly afterwards returned. Andrew Sparrman, the Swedish naturalist, who explored in the Sneeuberg in 1776, learned from the Hottentots that eight or ten days' journey north there was a large perennial stream, which he rightly concluded was the groote-rivier of Hop. The next year Captain (afterwards Colonel) R. J. Gordon, a Dutch officer of Scottish extraction, who commanded the garrison at Cape Town, passed the river in its middle course at the point indicated by Sparrman and named it the Orange in honour of the prince of Orange. In 1778 Lieut. W. Paterson, an English traveller, reached the river in its lower course, and in 1779 Paterson and Gordon journeyed along the west coast of the colony and explored the mouth of the river. F. Le Vaillant also visited the Orange near its mouth in 1854. Mission stations north of the Orange were established a few years later, and in 1813 the Rev. John Campbell, after visiting Griqualand West for the London Missionary Society, traced the Harts river, and from its junction with the Vaal followed the latter stream to its confluence with the Orange, journeying thence by the banks of the Orange as far as Pella, in Little Namaqualand, discovering the great falls. These falls were in 1855 visited and described by G. A. Farini, from whom they received the name of the Hundred Falls. The source of the Orange was first reached by the French Protestant missionaries T. Arbousset and F. Daumas in 1826.

The story of Hop's expedition is told in the Nouvelle description du Cap de Bonne Espérance (Amsterdam, 1778). Lieut. Paterson gave his experiences in A Narrative of Four Journeys into the Country of the Hottentots and Cafraria in the Years 1777-1778-1779 (London, 1780). See also Campbell's Travels in South Africa (London, 1815), Arbousset and Daumas' Relation d'un voyage d'exploration au nord-est de la colonie du Cap de Bonne Espérance en 1826 (Paris, 1842), and Farini's Through the Kalahari Desert (London, 1886).

**ORANGE** (*Citrus Auranium*). The plant that produces the familiar fruit of commerce is closely allied to the citron, lemon, and lime, all the cultivated forms of the genus *Citrus* being so nearly related that their specific demarcation must be regarded as somewhat doubtful and indefinite. The numerous kinds of orange chiefly differing in the external shape, size and flavour of the fruit may all probably be traced to two well-marked varieties or sub-species—the sweet or China orange, *var. sinensis*, and the bitter orange or bigarade, *var. amara*.

The **Bitter Seville or Bigarade Orange** (*C. Auranium, var. amara* (*C. vulgaris* of Risso)), is rather a small tree, rarely exceeding 30 ft. in height. The green shoots bear sharp axillary spines, and alternate evergreen oblong leaves, pointed at the extremity, and with the margins entire or very slightly serrated; they are of a bright glossy green tint, the stalks distinctly winged and, as in the other species, articulated with the leaf. The fragrant white or pale pinkish flowers appear in the summer months, and the fruit, usually round or spheroidal, does not perfectly ripen until the following spring, so that flowers and both green and mature fruit are often found on the plant at the same time. The bitter aromatic rind of the bigarade is rough, and dotted closely over with concave oil-cells; the pulp is acid and more or less bitter in flavour.

**The Sweet or China Orange**, including the Malta or Portugal orange, has the petals less distinctly winged, and the leaves more ovate in shape, but chiefly differs in the fruit, the pulp of which is agreeably acidulous and sweet, the rind comparatively smooth, and the oil-cells convex. The ordinary round shape of the sweet orange fruit is varied greatly in certain varieties, in some being greatly elongated, in others much flattened; while several kinds have a conical protuberance at the apex, others are deep ribbed or furrowed, and a few are distinctly "horned" or lobed, by the partial separation of the carpels. The two sub-species of orange are said to reproduce themselves infailliby by seed; and, when hybridizing is prevented, the seedlings of the sweet and bitter orange appear to retain respectively the more distinctive features of the parent plant.

Though now cultivated widely in most of the warmer parts of the world, and apparently in many completely naturalized, the diffusion of the orange has taken place in comparatively recent historical periods. To ancient Mediterranean agriculture it was unknown; and, though the later Greeks and Romans were familiar with the citron as an exotic fruit, their "median apple" appears to have been the only form of the citrine genus with which they were acquainted. The careful researches of Gallesio have proved that India was the country from which the orange spread to western Asia and eventually to Europe. Oranges are at present found wild in the jungles along the lower mountain slopes of Sylhet, Kumaon, Sikkim and other parts of northern India, and, according to Royle, even in the Nilgiri Hills; the plants are generally thorny, and present the other characters of the bitter variety, but occasionally wild oranges occur with sweet fruit; it is, however, doubtful whether either sub-species is really indigenous to Hindustan, and De Candolle is probably correct in regarding the Burmese peninsula and southern China as the original home of the orange. Cultivated from a remote period in Hindustan, it was carried to south-western Asia by the Arabs, probably before the 9th century, towards the close of which the bitter orange seems to have been well known to that people; though, according to Mas'ud, it was not cultivated in Arabia itself until the beginning of the 10th century, when it was first planted in Omán, and afterwards carried to Mesopotamia and Syria. It spread ultimately, through the agency of the same race, to Africa and Spain, and perhaps to Sicily, following
everywhere the tide of Mohammedan conquest and civilization. In the 12th century the bigarade was abundantly cultivated in all the Levant countries, and the returning soldiers of the Cross brought it from Palestine to Italy and Provence. An orange tree of this variety is said to have been planted by St Dominick in the year 1200, though the identity of the one still standing in the garden of the monastery of St Sabina at Rome, and now attributed to the energetic friar, may be somewhat doubtful. No allusion to the sweet orange occurs in contemporary literature at this early date, and its introduction to Europe took place at a considerably later period, though the exact time is unknown. It was commonly cultivated in Italy early in the 16th century, and seems to have been known there previously to the expedition of Da Gama (1497), as a Florentine narrator of that voyage appears to have been familiar with the fruit. The importation of this tree into Europe, though often attributed to the Portuguese, is with more probability referred to the enterprise of the Genoese merchants of the 15th century, who seem to have found it growing abundantly then in the Levant. The prevailing European name of the orange is sufficient evidence of its origin and of the line taken in its migration westward. The Sanskrit designation nagrungo, becoming narunges in Hindustani, and corrupted by the Arabs into naranj (Spanish naranja), passed by easy transitions into the Italian arancia (Lateinized aurantium), the Romance orangi, and the later Provençal orange. The true Chinese variety, however, was undoubtedly brought by the Portuguese navigators direct from the East both to their own country and to the Azores, where now luxuriant groves of the golden-fruited tree give a modern realization to the old myth of the gardens of the Hesperides. 1 Throughout China and in Japan the orange has been grown from very ancient times, and it was found diffused widely when the Indian Archipelago was first visited by Europeans. In more recent days its cultivation has extended over most of the warmer regions of the globe, the tree growing naturally and producing fruit abundantly wherever the heat is sufficient and enough moisture can be supplied to the roots; while night-frosts occur in winter or spring the culture becomes more difficult and the crop precarious.

The orange flourishes in any moderately fertile soil, if it is well drained and sufficiently moist; but a rather stiff loam or calcareous marl, intermingled with some vegetable humus, is most favourable to its growth. Grafting or budding on stocks raised from the seed of some vigorous variety is the plan usually adopted by the cultivator. The seeds, carefully selected, are sown in well-prepared ground, and the seedlings removed to a nursery-bed in the fourth or fifth year, and, sometimes after a second transplantation, grafted in the seventh or eighth year with the desired variety. When the grafts have acquired sufficient vigour, the trees are placed in rows in the permanent orangery. Propagation by layers is occasionally adopted; cuttings do not readily root, and multiplication from cuttings is usually of little advantage in the orange grove. The distance left between the trees in the permanent plantation or grove varies according to the size of the plants and subsequent culture adopted. In France, when the trunks are from 5 to 6 ft. in height, a space of from 16 to 26 ft. is left between; but the dwarfer trees admit of much closer planting. In the West Indies and Azores an interval of 24 or even of 30 ft. is often allowed. The ground is kept well stirred between the trunks, and the roots manured with well-rotted dung, guano or other highly nitrogenous matter; shallow pits are sometimes formed above the roots for the reception of liquid or other manures; in dry climates water must be abundantly and frequently supplied. The trees require regular and careful pruning, the heads being trained as nearly as possible to a spherical form. Between the rows melons, pumpkins and other annual vegetables are frequently raised. In the genus Citrus the orange is often trained as an espalier, and with careful attention yields fruit in every profusion when thus grown. In favourable seasons the oranges are produced in great abundance, from 400 to 1000 being commonly borne on a single plant in full bearing, while on large trees the latter number is often vastly exceeded. The trees will continue to bear abundantly from fifty to eighty years, or even more; and some old orange trees, whose age must be reckoned by centuries, still produce their golden crop; these very ancient trees are, however, generally of the bitter variety.

Oranges intended for export to colder climates are gathered long before the deep tint that indicates maturity is attained, the fruit ripening rapidly after picking; but the delicious taste of the mature China orange is never thus acquired, and those who have not eaten the fruit in a perfectly ripe state have little idea of its flavour when in that condition. Carefully gathered, the oranges are packed in boxes, each orange being wrapped in paper, or with dry maize husks or leaves placed between them. The immense quantities of this valuable fruit imported into Britain are derived from various sources, the Azores ("St Michael's" oranges), Sicily, Portugal, Spain and other Mediterranean countries, Jamaica, the Bahamas and Florida, California, &c. In Florida the bitter orange has grown, from an unknown period, in a wild condition, and some of the earlier botanical explorers regarded it as an indigenous tree; but it was undoubtedly brought by the Spanish colonists to the West India Islands, and was probably soon afterwards transplanted to Florida by them or their buccaneering enemies; its chief use in America is for stocks on which to graft sweet orange and other species of Citrus.

Orange cultivation has been attempted with success in several parts of Australia, especially in New South Wales, where the orange groves near Paramatta yield an abundant colonial supply. The orange-reefs of Queensland and South Australia likewise produce well. In many of the Pacific Islands the plant has been long established. There are numerous varieties of the sweet orange, a few of which deserve mention on account of some striking peculiarity. Maltese or Blood oranges are characterized by their flavour, the more or less crimson stain on the skin, and the profound crimson colour of the fruit when split open. Gallesia refers to the blood orange as cultivated extensively in Malta and Provence; they are largely grown in the Mediterranean region in the present day, and have been introduced into America. So-called navel oranges have an umbilical mark on the apex of the fruit due to the production of an incipient second whorl of carpels. Baptiste Ferrari, a Jesuit monk, in his work Hesperides, sive De malorum aurorum cultura et usus Libri Quatuor, published at Rome in 1646, figures and describes (pp. 403, 405) such an orange. The mandarin orange of China, sometimes regarded as a distinct species, C. nobilis, is remarkable for its very flat spheroidal fruit, the rind of which readily separates with the slightest pressure; the pulp has a peculiarly luscious flavour when ripe. The small Tangerine oranges, valued for their fine fragrance, are derived from the mandarin.

Diseases.—Several are caused by fungi, others by insects. Of the fungus diseases that known as foot-rot in Florida and mal-di-gomma in Italy is very widely distributed. It occurs on the lower part of the trunk and the main roots of the tree, and is indicated by exudation of gum on the bark covering the diseased spot. The diseased patches spread into the wood, killing the tissues, which emit a foetid odour; the general appearance of the tree is unhealthy, the leaves become yellow and the twigs and young branches die. A fungus, Fusarium limonis is found associated with the disease, which is also fostered by faulty drainage, a shaded condition of the soil, the use of rank manures and other conditions. For treatment the soil should be removed from the base of the trunk, the diseased patches cut away and the wound treated with a fungicide. Decay of oranges in transit often causes serious losses; this has been shown to be due to a species of Penicillium, of which the germinating spores penetrate the skin of damaged fruits. Careful picking, grading and packing have much reduced the amount of lost from this cause. Another fungus disease, called also, has been very injurious to the lemon and bitter orange in Florida. It is caused by a species of Cladosporium, which forms numerous small warts on the leaves and fruits; spraying with a weak

1 The modern Arabic name, Bortukin (that is, Portuguese), shows that the China apple reached the Levant from the West.
solution of Bordeaux mixture or with ammoniacal solution of carbonate of copper is recommended. The sooty mould of orange, which forms a black incrustation on the leaves and also the fruit, probably occurs wherever the orange is cultivated. It is caused by species of Meliola; in Europe and the United States, by _M. Fenisii_ and _M. Camelliae_. The fruit is often rendered unsaleable and the plant is also injured as the leaves are unable properly to perform their functions. The fungus is not a parasite, but lives apparently upon the honey-dew secreted by aphides, &c., and is therefore dependent on the presence of these insects. Spraying with resin-wash is an effective preventive, as it destroys the insects. Several insect enemies attack the plant, of which the scale insect _Aspidiotus_ is the most injurious in Europe and the Azores. In Florida another species, _Myiiaspis citricola_ (purple scale), sometimes disfigures the fruit to such an extent as to make it unfit for market. Several species of _Aleyrodas_ are insect pests on leaves of the orange; _A. citri_, the white fly of Florida, is described as the most important of all the insect pests of the crop in Florida at the present time, and another species, _A. Howardii_, is a very serious pest in Cuba. Cold weather in winter has sometimes proved destructive in Provence, and many plantations were destroyed by the hard frosts of 1780 and 1820.

Besides the juice used as an ingredient of a beverage, there is another article of drink that of the sweet orange, abundant in citric acid, possesses in a high degree the antiscorbutic properties that render the lemon and lime so valuable in medicine; and the free consumption of this fruit in the large towns of England during the winter months has doubtless a very beneficial effect on the health of the people. The juice is sometimes employed as a cooling drink in fevers, as well as for making a pleasant beverage in hot weather.

The bitter orange is chiefly cultivated for the aromatic and tonic qualities of the rind, which render it a valuable stomachic. Planted long ago in Andalusia by the Moorish conquerors, it is still extensively grown in southern Spain—deriving its common English name of "Seville" orange from the abundant groves that still exist around that city, though the plant is now largely cultivated elsewhere. The fruit is imported into Great Britain and the United States in considerable quantities for the manufacture of orange marmalade, which is prepared from the pulp and rind, usually more or less mingled with the pulp of the China orange. In medicine the fresh peel is largely employed as an aromatic tonic, and often, in tincture and syrup and "orange wine," as a vehicle to disguise the flavour of medicine's nauseous remedies. The chief constituents are three glucosides, hesperidin, isohesperidin and aurantiamarin, the latter being the bitter principle; and an oil which mainly consists of a terpene known as limonene. The essential oil of the rind is collected for the use of the perfumer, being obtained either by the pressure of the fresh peel against a piece of sponge, or by the process known as _exceller_, in which the skin of the ripe fruit is scraped against a series of points or ridges arranged upon the surface of a peculiarly-shaped dish or broad funnel, when the oil flows freely from the broken cells. Another fragrant oil, called in France _esseence de petit grain_, is procured by the distillation of the leaves, from which also an aromatic water is prepared. The flowers of both sweet and bitter orange yield, when distilled with water, the "oil of Neroli" of the druggist and perfumer, and likewise the fragrant liquid known as "orange-flower water," which is a saturated solution of the volatile oil of the fresh flowers. The candied peel is much in request by cook and confectioner; the favourite liqueur sold as "curaçoa" derives its aromatic flavour from the rind of the bigarade. The minute inappreciable oranges that drop from the trees are manufactured into "issue-peas"; from those of the sweet orange in a fresh state a sweetmeat is sometimes prepared in France. Orange trees occasionally acquire a considerable diameter; the trunk of one near Nice, still standing in 1780, was so large that two men could scarcely embrace it; the tree was killed by the intense cold of the winter of that year. The wood of the orange is of a fine yellow tint, and, being hard and close-grained, is valued by the turner and cabinetmaker for the manufacture of small articles; it takes a good polish.

Although the bitter "Pomax de Orange" were brought in small quantities from Spain to England as early as the year 1290, no attempt appears to have been made to cultivate the tree in Britain until about 1595, when some plants were introduced by the Carews of Beddington in Surrey, and placed in their garden, where, trained against a wall, and sheltered in winter, they remained until destroyed by the great frost of 1739-1740. In the 18th century the tree became a favourite object of conservatory growth; in the open air, planted against a wall, and covered with mats in winter, it has often stood the cold of many seasons in the southern counties, in such situations the trees occasionally bearing abundant fruit. The trees are usually imported from Italy, where, especially near Nervi, such plants are raised in great numbers for exportation; they are generally budded on the stocks of some free-growing variety, often on the lemon or citron.

The orange has been usually cultivated in England for the beauty of the plant and the fragrance of its blossoms, rather than for the purpose of affording a supply of edible fruit. The latter can, however, be easily grown in a hot-house, some of the fruits thus grown, especially those of the pretty little Tangerine variety, being superior in quality to the imported fruit. The best fruits are grown in houses roofed with glass on both sides, the height and other conditions being similar to those recommended for stove plants. The trees may be planted out, a row on each side a central path, in a house of moderate width. They will flourish in a compost of good, light, turfy loam and well-decayed leaf-mould in equal proportions, to which a little broken charcoal may be added. Each year the trees should be top-dressed with a similar compost, removing some of the old soil beforehand. The trees, if intended to be permanent, should be placed 10 to 12 ft. apart. It will often be found more convenient to grow the plants in pots or tubs, and then bottom heat can be secured by placing them on or over a series of hot-water pipes kept near to or above the ground level. The pots or tubs should be thoroughly well drained, and should not be too large for the plants; and repotting should take place about every third year, the soil being top-dressed in intervening years. The temperature may be kept at about 50° or 55° in winter, under which treatment the trees will come into bloom in February; the heat must then be increased to 60° or 65° in the day time, and later on to 80° or 95°. Throughout the growing season the trees should be watered twice or thrice a day; this whole material assistance in the above described in the small greenhouses. When the trees are in bloom, however, they must not be syringed, but the house must be kept moist by throwing water on the pathways a few times during the day. When the flowers have fallen the syringing may be used again daily in the early morning and late afternoon. The fruit may be expected to ripen from about the middle of October to January, and if the sorts are good will be of excellent quality. When the trees are at rest the soil must not be kept too wet, since this will produce a sickly condition, through the loss of the small feeding roots. The trees require little pruning or training. The tips of the stronger shoots are just pinched out when they have made about 6 in. of growth, but when a branch appears to be robbing the rest, or growing ahead of them, it should be shortened back or tied down.

When grown for the production of flowers, which are always in great request, the plants must be treated in a similar manner to that already described, but may do without bottom heat.

There are many varieties of the sweet orange that may be grown under glass in the British Isles. Amongst the best for dessert is the _St Michaels_, a heavy cropper with large juicy fruits; and closely related are _Bidentown_, _Egg_, _Dom Louise_, _Sustain_, _Excelsior_ and _Brown's Orange_. The _White Orange_,
so called from its pale skin, is excellent. Silver or Platea is a sweet, pale-coloured variety with a curious weal-like orange shade. Abaco fruit being a smaller but heavy. Emblica, or Washington Naval Orange, produces splendid fruit under glass. The Jaffa, with large obo long fruits and large waxy wrinkled leaves, although a shy bearer, makes up for this in the size of its fruits. The Maltese Blood Orange is remarkable for the blood-like stains in the pulp, although these are not present in every fruit even on the same tree.

Other kinds of oranges are the Tangerine with small aromatic fruits and willow-like leaves. The Seville orange is a handsome flower-tree, but its fruits are bitter and used only for preserving and marmalade.

ORANGEBURG, a city and the county-seat of Orangeburg county, South Carolina, U.S.A., on the North Edisto river, 50 m. S. by E. of Columbia. Pop. (1800) 2964; (1900) 4453 (2315 negroes); (1910) 5906. Orangeburg is served by the Atlantic Coast Line and the Southern railways. It is the seat of Claflin University for negroes, and of the State Colored Normal, Industrial, Agricultural and Mechanical College. Claflin University, incorporated in 1846, was named in honour of the Cline brothers (1757-1857) of Massachusetts, and is under the control of the Freedmen's Aid and Education Society of the Methodist Episcopal Church. In 1906 it had 25 instructors and 538 students (241 men and 297 women). The State Colored Normal, Industrial, Agricultural and Mechanical College was established here by the state in 1872 as the College of Agriculture and Mechanics' Institute (for negroes), on property immediately adjoining the campus of Claflin University, and the two schools were under one management (although otherwise distinct and separate) until 1896, when the present name of the state college was adopted. Among the city's manufactures are cotton-seed oil, cotton (yarn and cloth), lumber, bricks, concrete and turpentine. The municipality owns the water-works and the electric-lighting plant. A trader and trapper settled on the site of what is now Orangeburg in 1794. In 1755 a company of Germans and Swiss established the first real settlement and named it Orangeburg, in honour of the prince of Orange. Orangeburg was incorporated as a town in 1851, and was first charted as a city in 1855.

ORANGE FREE STATE, an inland province of British South Africa; formerly— from 1854 to 1900—an independent republic. From May 1900 to June 1910 it was known as the Orange River Colony, since when under the style of Orange Free State it has formed a province of the Union of South Africa. It lies north of the Orange and south of the Vaal rivers, between 26° 30' and 30° 40' S. and 24° 20' and 29° 40' E., and has an area of 50,392 sq. m., being nearly the size of England. It is surrounded by other British possessions, being bounded N. by the Transvaal, E. by Natal, S.E. by Basutoland, S. and W. by the Cape province. Its greatest length is 356 m., its greatest breadth 304 m.

Physical Features. The country forms part of the inner tableland of South Africa and has an elevation of between 4000 and 5000 ft. On the N.E. or Natal border the crest of the Drakensberg forms the frontier. The northern slopes of Mont aux Sources (11,000 ft.), the highest land in South Africa, are within the province, as are also the Drakens' Berg (3024 ft.), the mountain from which the Kaap Kog (7500 ft.) and Platberg (about 8000 ft.), near Harrismith. Though rugged in places, with outlying spurs and secondary chains, the westward slopes of the Drakensberg are much gentler than the eastern or Natal versant of the chain. Several passes exist through the mountains, that of Van Reenen, 5500 ft., being traversed by a railway. From the mountainous district the country dips gradually westward. No natural boundary marks the western frontier, a line across the veld (separating it from the Griqualand West district of the Cape) from the Orange to the Vaal rivers.

The aspect of the greater part of the country is that of vast undulating treeless plains, diversified by low lands and isolated tafelbergs and spitzkops, indicating the former level of the country. These hills are either of sandstone or ironstone and in altitude vary from about 4000 ft. to 5300 ft. Ironstone hills are numerous in the south-west districts. The whole country forms part of the drainage basin of the Orange river, its streams, with insignificant exceptions, being tributaries of the Vaal or Caledon affluents of that river. The watershed between the Vaal and Caledon is formed by chains of hills, which, leaving the main range of the Drakensberg at Mont aux Sources, run south-east between the Vaal and Caledon. These hills are known as the Roodebergen, Wittebergen, Korannaah, Vierfontein, and the rising 7000 ft. The well-known Thaba Nchu (Black Mountain) is an isolated peak between this range and Bloemfontein. The Vaal and Caledon rivers are both quite large; the Vaal is and is typical veld; the valley of the Caledon, sheltered eastward by the Maluti Mountains in Basutoland, is well watered and extremely fertile. The Caledon, from its source in Mont aux Sources to Janmopper Drift near Wepener, forms the boundary of the province on its southern border; here the banks in the Vaal and Caledon on both sides of the Caledon is in the province. Here, between the Caledon and the Orange, is the fertile district of Rouxville. The north bank of the Orange, from the Koron Sport confluence to a point at which the river leaves the Cape Town to Kimberley crosses the river, forms the southern frontier of the province. The chief tributaries of the Vaal (q.v.) wholly or partly within the province are, going from east to west, the Tloko River from its source to its confluence with the Vaal divides the Free State from the Transvaal), the Wilge, Rhenoster, Vet, Modder and Reit. The Sand river, on whose banks the convention recognizing the independence of the Transvaal Boers was signed in 1852, is a tributary of the Vaal, and the rivers draining Griqualand West above Kimberley. The river beds are generally 40 to 80 ft. below the level of the surrounding land. Most of the rivers have a considerable slope and none is navigable. Except the Vaal and Vaal Orange, they are dry or nearly dry for three or four months in the year. In some cases their beds fill with raging torrents. The valleys of the Modder, Reit and the lower Caledon contain rich alluvial deposits. Besides the rivers water is obtained from numerous springs. A remarkable feature of the eastern plains is the occurrence of rich and well-watered forests grouped together in extensive areas, especially in the Boshof district.

Geology. Except a small area around Vrededorp in the north, the whole of the province is occupied by rocks of Karroo or Karroo age. At Vrededorp there is a granite mass, belonging to the Swaziland series, regarded as being an intrusive in the overlying Witwatersrand series by G. A. F. Molengraaff, but to be of older date by F. A. Hatch. This black granite is surrounded by a series of dolomitic and argillaceous rocks of Karroo age, which forms the lower portion of which consists of quartzites and slates and the upper portion of quartzites and conglomerates. At Hoopstad and at Sinkhoutboom the Witwatersrand series is unconformably overlain by these rocks which are from 500 to 400 ft. thick and belong to the Vaal River System. The Black Reef series of quartzites and conglomerates and dolomite form a narrow outcrop resting unconformably upon the last-mentioned system. Of the Karroo System all the rocks from Hoopstad to the Cave Sandstone of the Stormberg series (see Capetown Cathedral) are represented; but these rocks have not been so minutely subdivided as in the Cape. The Dwyka Conglomerate forms a narrow outcrop in the northern part, and is known from boreholes to extend over large areas beneath the Ecca Shales and to rest directly on rocks of Karroo age. At Vierfontein a seam of coal is worked above it. The Ecca series extends over the major portion of the province. It consists mainly of sandstones, but these are often thin-bedded and pass into shale, and pro pulsions and plantified slates are frequently found. The Beaufort series occupies a portion of the area formerly regarded as being composed of the Stormberg beds. The prevailing rocks are sandstones, mudstones and shales. Repen mor horizon is prominent; bedded lignite also found. The Stormberg series is confined to the north-east. The climate.—Cut off from the warm, rain-bearing winds of the Indian Ocean by the Drakensberg, the country is swept by the westerly winds, usually dry and warm. The weather is generally subject to hot, dry winds from the north. The westerly wind is almost constant and, in conjunction with the elevation of the land, greatly modifies the climate. In the usual sub-tropical conditions of South Africa the climate is dry and bracing. The climate indeed is noted for its healthiness, the chief drawback being dust-storms. The average temperature for the four winter months—May-August—is 49° F.; hard frosts are frequent, and then temperatures may fall as low as 29° F. The average temperature is 66°, December-February being the hottest months. The average daily range of the thermometer is from 25° to 30°.

the highest recorded range in one day being 74° (from 20° to 94°). Rain falls from many to sixty or seventy days during the year, chiefly in the summer (December-April). Rain is generally preceded by thunder and lightning and falls heavily for a short period. Most of the water runs off the surface into the spruits and in a large extent cut down by the early white immigrants. Thorny acacias, euphorbias and aloes are still, however, found in patches on the plains. Timber trees are almost confined to the river valleys, where the rainfall is heavier. Agathis, monkey-puzzle and the tree ferns of Polynesia cover the upland and in deep gorges, the wild fig are found. The tobacco plant also grows wild. In most regions ferns and mosses, the arum and other broad flat-leaved plants are found. The characteristic plants are thorny and small leaved, or else bulbous. Among wild plants the cladda boontjie provides tanning material equal to oak bark. European fruit trees and vines flourish in certain localities, while in the drier regions the Australian wattle, gum trees and pepper trees have been introduced with success.

The fauna has undergone a great alteration since the first white settlers entered the country. Big game was then abundant. The elephant, giraffe, lion, leopard, hyena, zebra, buffalo, gn, guagga, kudu, eland and many other large or small animals roamed the country. The number of rhinoceros and crocodile lived in or frequented the river, and ostriches and baboons were numerous. The immigrant farmers ruthlessly shot game of all kinds and most of the animals named were exterminated. So far as the province was concerned, the only large species of game that may be found are rhinoceroses and baboons, men, the leopard, red lynx (Felis caracal), spotted hyena, aard wolf, wild cat, long-eared fox, jackals of various kinds, the dassie or rock rabbit, the scaly ant, the ant bear (aardvaark), the Cape genet and the springbok, a real fabled animal. Antelope of any kind are now scarce; a few white-tailed gnu are preserved. None of the dangerous wild beasts is common, but there are several varieties of poisonous snakes. Scorpions and tarantulas and large and small lizards, vipers, adders, pit vipers and moths and flies are abundant. Locusts are an intermittent plague. There are few earthworms or snails. The birds include eagles—some are called hammerers on their occasional attacks on young game, crows, cranes, small white heron, quolls, partridges, korhaans, wild geese, duck, and guinea fowl, swallows, finches, starlings, the mossee or Cape sparrow, and the white bird, noted for the length of its tail in summer. Barbel and yellow muddish are found in certain streams.

**Inhabitants.**—The Bushmen (q.v.) are, presumably, the oldest inhabitants of this, as of many other parts of South Africa. Next came the Hottentots (q.v.), and in the 16th century Bantu negroes of the Bechuana tribes appear to have established themselves in the country. The Barolong, one of the oldest Bechuana tribes, are believed to have entered the country subsequently to the Bakuena, the particular tribe from which the general name of the race is derived (see Bechuana; and Transvaal: Inhabitants). Clans representing the southern Bakuena were welded together into one tribe in the 19th century, and are now known as Basuto (see Basutoland). The Basuto were already a strong force when the first white settlers, Dutch farmers from the Cape, entered the country in 1824; the white man, since then, has continued to be the dominant force of British, particularly of European, influence. Since the advent of the whites there has been a considerable immigration of Zulus. The majority of the inhabitants live in the eastern part of the country; the arid regions west of the main railway line containing a scanty pastoral population and no towns of any size. The first census, taken in 1880, showed a total population of 133,518; in 1890 there were 207,503 inhabitants—an increase in ten years of 55.41%—and at the census of 1904 there were 387,315 inhabitants, a further increase of 85.56%. The density in 1904 was under 8 persons per sq. m. The inhabitants are officially divided into "Europeans or white," "aboriginal natives" and "mixed and other coloured races." Between 1880 and 1904 the proportion of whites dropped from 45.76% to 36.84%. Of the 126,079 white inhabitants in 1904, 85,036 were born in the province; 26,727 in the Cape; 3116 in the Transvaal; 18,497 in the United Kingdom. Of the 276,000 European immigrants born in non-British states 1925 came from Russian Poland.

According to the 1904 census classification the "aboriginal inhabitants" numbered in that year 390,149. In this term are included, however, Zulu-Kaffir immigrants. The tribe most largely represented was the Basuto (130,213 persons), former owners of considerable tracts in the eastern part of the country, now known as "The Conquered Territory." In the eastern districts of Harrismith, Bethlehem, Ficksburg and Ladybrand the Basutos are largely concentrated. Barolong numbered 37,908 and other Bechuana 5115. Of the Zulu-Kaffir tribes Zulus proper numbered 35,275, Fingoos 6275, and Ama Xosa 5376 (see Kaffirs; and Zululand: Inhabitants). The Bushmen numbered 4048 persons. Of these 1313 were in the Bloemfontein district. The Bushmen have left in drawings on caves and in rocks traces of their habitations in regions where they are no longer to be found. In Thaba hchu a pett Barolong state enjoyed autonomy up to 1884, and the majority of the Barolong are found in that district and the adjoining district of Bloemfontein. The Bushmen are mostly found in that part of the Transvaal near Zoulubind. In 1904 the number of persons belonging to mixed and other races was 157,775.

The proportion between the sexes was, for all races, 84:35 females to 100 males; for white inhabitants only 74:91 females to 100 males; for aboriginal inhabitants only 90:86 females to 100 males. Of the population above fifteen years old 55.87% of the men and 33.69% of the women were unmarried. Among whites for every 100 unmarried men there were 65.33 unmarried women; there were 93.04 married women for every 100 married men, and 173.81 widows for every 100 widowers.

Classified by occupations the census of 1904 gave the following results: dependants, mainly young children, 28.84% agriculture, 39.6% commercial and industrial pursuits, 7.6% professional, 3.18% domestic; including women living at home other than those helping in farm work, 15.75%. Divided by races 8.17% of the whites were engaged in professional work and only 0.46% of the coloured classes.

**Chief Towns.**—The capital, Bloemfontein (pop. in 1904, 33,883), is fairly centrally situated on the trunk railway to Johannesburg. Kroonstad (pop. 7191) lies 127 m. N.N.E. of Bloemfontein on the same railway line. Harrismith, 8300, is in the N.E. of the colony, also on the railway, and the line runs between the Transvaal and the Orange Free State. The line runs between the Transvaal and the Orange Free State. The line runs between the Transvaal and the Orange Free State. These towns are the chief centres for emigration to the Transvaal, and the railway is built in order to facilitate the movement of the immigrants. There are several important railway stations on the line, including Winburg, 2762, lies between Bloemfontein and Kroonstad. All the towns are noted for their gardens and fruit growing. The railway, going from south to north, is Springfontein, 1000, an important railway junction; Trompsburg, 1378; Edenburg, 1562, and Brandfort, 1977. In the S.E. Thaba nchu, 1734, Zaenron, 1157, Dordtfontein, 1771, are barrier stations, and the line passes over the range of Christian Deli, Reddersburg, 750, Smithfield, 999, and Rouxville, 990. These are all centres of fine agricultural regions. Bethulie, 1666, on the Orange river, in the "Conquered Territory," has been the scene of the town of Free State Protestant missionaries since 1832, and possesses a fine park. Thru passes the main line from East London. In the N.E. are: Bethlehem, 1777, on the railway, 57 m. W. of Harrismith, an agricultural and coal-mining centre; Senekal, 56,510, on the railway, 28 m. W. of Harrismith, a wool-marking station, 10,540; Reitz, 526. In the north-west of the trunk line are: Piets, 1732, finely situated on the Vaal, and Vrededorp, 759. Farther west and south are: Hoopstad, 455, on the Vet river; Boshow, 135, a fruit and vegetable centre, 30 m. N.E. of Kimberley, and Jacobsdal, 13 m. from the S.W. of the Transvaal, and Philip, 893, the home of the Griqua chief Adam Kok and named after the Rev. John Philip (q.v.). Fairesmire, 1365, a mining centre, 6 W. of Jagersfontein, and Koskifontein, 1657, where is a diamond mine. Many of the towns are noted for their gardens and are the chief centres for emigration to the Transvaal, and the railway is built in order to facilitate the movement of the immigrants. There are several important railway stations on the line, including Winburg, 2762, lies between Bloemfontein and Kroonstad. All the towns are noted for their gardens and fruit growing. The railway, going from south to north, is Springfontein, 1000, an important railway junction; Trompsburg, 1378; Edenburg, 1562, and Brandfort, 1977. In the S.E. Thaba nchu, 1734, Zaenron, 1157, Dordtfontein, 1771, are barrier stations, and the line passes over the range of Christian Deli, Reddersburg, 750, Smithfield, 999, and Rouxville, 990.
systems, (1) those connecting the province with the Cape and the Transvaal, and (2) those linking it with Natal.

The first system consists of a trunk line, formed by the junction of lines from Cape Town and Port Elizabeth, which crosses the Orange river, and thence, to the north, passes through Bloemfontein and Kroonstad, and ends the Transvaal at Vrijoups Drift (331 m. from Orvorys Port), being continued thence to Johannesburg. This line is joined at Springfontain by a railway from East London which crosses the Orange near Bethulie and thence runs the Caledon valley towards Kimberley, on the main line from Cape Town to Rhodesia, and from Springfontain a branch (56 m. long) goes past Jagersfontein to Fauresmith.

The second system is formed by a line leaving the Natal trunk railway at Ladysmith which crosses the Drakensberg at Van Reenen’s Pass and is continued thence to Harrismith near Bethlehem. At Bethlehem it divides, one branch going N.W. to Kroonstad (175 m. from the sea), and the other, by a line of 30 miles south of Drakensberg, along the Caledon valley to Moddersport near Ladybrand, and thence directly west to Bloemfontein. The distance from Van Reenen’s Pass to Bloemfontein by this route is 278 miles. The two systems, it will be seen, are doubly connected by lines between Bloemfontein and Kroonstad, and the lines running east from those towns afford the quickest connexion between Cape Town and Durban. Besides the lines enumerated there are various local lines, one branching at Sannah’s Post station from the Bloemfontein-Bethlehem line, and running south of Drakensberg, and from the same line crosses the Caledon to Masori, Basutoland. In 1910 there were in all 1060 m. of railway open in the province.

There are well-kept high-roads connecting all the towns, and a government coach system, running under the connexion of government officers, and is marked out by the axe of transport. The Cape cart is largely used, and the wagon, drawn by a team of oxen, is still employed by farmers to bring their produce to market. There is an extensive telegraphic system and a well-organized postal service.

Agriculture.—The chief industry is agriculture, including farming, stock raising, and stock rearing. The dry western plains are best adapted for sheep rearing, while the well-watered eastern regions are specially suited for the cultivation of cereals. Horses are extensively bred. The land under cultivation in 1904 was 371,515 morgen (a morgen is 2-11 acres) or about 1230 sq. m. The chief crop is mealies, the staple food of the natives; wheat, oats, Kaffir corn and oats coming next, and the cultivation of potatoes and vegetables is extensive. The chief fruits of the province are peanuts, pumpkins, tomatoes, and tobacco. The cultivation of tobacco was commenced between the census years 1890 and 1904. The chief crops in cultivation are potatoes, wheat, and oats. The most important crops are the maize and the maize, respective. The chief crops, however, are the maize and the maize, respectively. The chief fruits cultivated are the apricot, peach, apple, orange, lemon, pear, plum, and plum.

The rearing of live stock, the chief pursuit of the first Dutch settlers, remains one of the most important industries. Rinderpest and other epidemic diseases swept over the country in 1895-1896, and during the war of 1899-1902 the province was practically denuded of live stock. There was a rapid increase of stock after the close of hostilities. Sheep numbered over 5,000,000 in 1901, cattle over 4,000,000, horses over 1,000,000, goats (chiefly owned by natives) over 1,000,000. Large numbers of pigs are reared. Ostrich farming is growing in favour. The eastern and south-eastern districts have the greatest amount of sheep in the country, with the exception of the province of Cape Province, and the districts of the eastern Cape. The district of the Orange Free State has the largest number of cattle, horses, and Smithfield districts, goats in Philippi. The dairying industry is increasing. The Afrikaner cattle, powerful draught animals, large horned, bony and giving little milk, are being crossed with other breeds. The drilling of the Orange Free State in 1904, affords help to the farmers in various ways, notably in combating insect plagues, in experimental farms, and in improving the breed of horses, sheep and cattle.

Land. — The provisions of a Land Settlements Ordinance of 1901 over 1,500,000 acres of crown land had been by 1906 allotted, and in September 1909 there were 624 families, of whom over 570 were British, settled on the land. In 1907 a Land Settlements Board was appointed, having power and authority to purchase land and settle the affairs of those settlers. At the end of five years the Board was to hand over its duties to the government.

Diamond Mining and other Industries.—Next to agriculture the most important industry is that of diamond mining. The chief diamond mines are at Jagersfontein (g.) and Koffiefontein. There are also diamond mines in the Winburg and Kroonstad districts, and near Ficksburg, where old workings have been found 40 ft. deep. The alluvial deposits on the banks of the Vaal, N.E. of Kimberley, yield occasional diamonds of great purity. The value of the output from the diamond mines rose from £224,000 in 1890 to £1,508,000 in 1898. The war hindered operations, but the output was valued at £648,000 in 1904 and at £1,048,000 in 1909.

Coal-mines are worked in various districts in the north near the Vaal and the Vaal, notably at Koffiefontein, and at Clydesdale, which lies a few miles south of the Vaal. Before 1906 the mines were little worked; in that year the output was 118,000 tons, while in 1907 over 500,000 tons were raised. It dropped to 470,000 in 1909 owing to loss of railway contracts.

Petroleum has been found, but up to 1909 was not worked; iron ore exists near Kroonstad and Vredefort, but it also is not worked. Petroleum has been found in the Ficksburg, Ladysbrand and Harrismith districts, and is pumped to a limited extent. Gold is worked at a few places, and is worked at a few places, and is worked in the Basutoland and the Vaal, near Jacobsdal, and Haagenstad, to the west of Brandfort. In 1907 the output had increased to nearly 23,000,000 lb.

Trade.—The bulk of the direct trade of the country is with the Cape, Natal, and Basutoland. Its exports consist of live stock (cattle, horses, mules, sheep, and goats), wool, mohair, coal, wheat and eggs. Except the diamonds, which go to London via Cape Town, all the exports are taken by the neighbouring countries. The value of British origin, are cotton goods, clothing and haberdashery, leather, boots, &c., hardware, sugar, coffee, tea and furniture.

The volume of trade in 1898, as represented by imports and exports, was £1,675,000. In 1907 the imports were £3,114,000, and the exports £3,191,000. For the years beginning on June 30, 1902, that is immediately after the close of hostilities, the imports increased from £2,450,000 to £3,057,000, the exports from £285,000 to £3,057,000. For the fiscal year 1908-1909 the imports valued £3,949,000, the exports at £3,558,000. About a third of the imports are the produce or manufactures of other South African countries. Exported goods re-exported are of comparatively slight value—some £381,000 in 1908-1909.

Constitution.—From July 1907 to June 1910 the province was a self-governing colony. It is now represented in the Union government by sixteen senators and seventeen members of the house of assembly. For provincial purposes the province is divided into single-member constituencies. The franchise is given to all adult white male British subjects. There is no property qualification, but six months’ residence in the province is essential. There is a biennial registration of voters, and every five years the electoral areas are to be redivided, with the object of giving to each constituency an approximately equal number of voters. The qualifications for membership of the assembly are the same as those for voters.

At the head of the provincial government is an administrator (who holds office for five years) appointed by the Union ministry. This official is assisted by an executive committee of four members elected by the provincial council. The provincial council consists of 25 members (each representing a separate constituency) elected by the parliamentary voters and has a statutory existence of three years. Its powers are strictly local and delegated. The control of elementary education was granted to the council for a period of five years following the establishment of the Union.

Justice.—The law of the province is the Roman-Dutch law, so far as not already modified and adapted to the conditions of the country. The magistrates courts, which date from 1881, are the lowest courts and are administered by the chief magistrates. The Supreme Court has jurisdiction in all civil and criminal matters, the Chief Justice being the president. From it appeals can be made to the Appellate Division of the Supreme Court. Criminal cases are tried before one judge and a jury of nine, who must give a unanimous opinion. Circuit courts are also held by judges of the provincial court.

Finance.—The bulk of the revenue, e.g., that derived from customs and railways, is now paid to the Union government, but the provincial council has power to levy taxes and (with the consent of the Union ministry) to raise loans for strictly provincial purposes. In 1879-1871, when the province was an independent state and possessed neither railways nor diamond mines, the revenue was £97,000 and the expenditure £76,000; in 1884-1885 the revenue had risen to £228,000 and the expenditure to £229,000; in 1898, the last full year of the republican administration, the figures
were; revenue, including railway profits, £729,000; expenditure, including outlay on new railways, £92560. Omitting the figures during the war period, the figures for the year ending June 1902 were revenue, £956,000; expenditure, £839,000. The depression in trade which followed caused a reduction in revenue, the average for 1903-1908 being £826,000; an expenditure of £819,000. These figures are exclusive of railway receipts and expenditure (see Transvaal: Finance).

Religion.—The vast majority (over 95%) of the white inhabitants are Christians and about 76% belong to the Dutch Reformed Church, while another 3% are adherents of the very similar organization, the Geretsoemerk Kerk. Anglicans are the next numerous body, forming 12-53% of the white population. The Wesleyans number nearly 1% of the inhabitants. The Roman Catholics number 2-30% of the whites, the head of their church in the province being a vicar apostolic. At the head of the Anglican community, which is in full communion with the Church of England, is the bishop of Bloemfontein, who is the representative of the bishop of Cape Town, and not only the Orange Free State, but Basutoland, Griqualand West and British Bechuanaland. All the churches named have missions to the natives, and in 1904, 104,289 aboriginals and 10,900 persons of mixed race were allocated for work. Among the later arrivals, the African Methodist Episcopal (Ethiopian) Church had 41,101 members, of whom only two were white. The Jewish community numbered 1616. Nearly 33% of the population, 127,637 persons, were returned as professing no religious and religious indifferent, which head are the natives who retain their primitive forms of belief, for which see KAFFERS, BECHUANAS, &c.

Education.—At the census of 1904, 32-57% of the total population could read and write; of the whites, 85-56% could read and write. Of the aboriginals, 8-15% could read and write; of the mixed and other races, 12-28%. In the urban areas the proportion of persons, of all races, able to read and write was 50-67%; in the rural areas the proportion was 26-64%. By sexes, 35% of males and 29-63% of females could read and write.

Elementary education is administered by the provincial councils, assisted by a permanent director of education. From 1900 to 1905 the schools were managed by the committee and paid for by the government and the fees borne by the government. They were of an undistinguished character and English was the medium of instruction. The teaching of Dutch was optional. In 1904 the Dutch Reformed Church started Christian National (i.e. Denominalional) Schools, but in March 1906 an agreement was come to whereby these schools were amalgamated with the government schools, and in June 1905 a further agreement was arrived at between the government and the leading religious denominations whereby a new system of "comparatively pure religious instruction," a purely historical character was given in all government schools for two hours every week, and might be given in Dutch. Further, ministers of the various denominations might give, on the special request of the children's parents, religious instruction in the children's congregations for one hour on one day in each week. The attendance at government schools reached in 1908 a total of nearly 20,000, as against 8000 in 1886, the highest attendance recorded under previous arrangements. By the act of the annexation, "religious instruction" was abolished. The colonial legislature passed an act (1908) which in respect to primary and secondary education made attendance compulsory on all white children, the fee system being maintained. English and Dutch were made languages of instruction as well as media of expression. Every school was under the supervision of a committee elected by the parents of the children. Schools were grouped in districts, and for each district there was a controlling board of nine members, of whom five were elected by the committees of the separate schools and the other four appointed by the government. Religious instruction could only be given by members of the school staff. Dogmatic teaching was prohibited during school hours, except in rural schools when parents requested such teaching to be given. The application of religious tests to the teachers was also abolished. In March 1906, by agreement between the colonial government and the Free State government, a special agreement was made respecting separate and public secondary education. In 1908 over 10,000 natives were in attendance at schools.

Provision is made for secondary education in all the leading town schools, which prepare pupils for matriculation. At Bloemfontein there are special schools for girls, a Reformed school and a normal school for the training of teachers. The Grey University College is a state institution providing university education for the whole province. It is affiliated to the university of the Cape of Good Hope.

History.

The country north of the Orange river was first visited by Europeans towards the close of the 18th century. At that time it was somewhat thinly peopled. The majority of the inhabitants appear to have been members of the Bechuana division of the Bantu, but in the valleys of the Orange and Vaal were Korannas and other Hottentots, and in the Drakensberg and on the western border lived a Boer republic. Early in the 19th century Griquas established themselves north of the Orange. Between 1817 and 1831 the country was devastated by the chief Mosilikatze and his Zulus, and large areas were depopulated. Up to this time the few white men who had crossed the Orange had been chiefly hunters or missionaries. In 1824 Dutch farmers from Cape Colony seeking pasture for their flocks settled in the country. They were followed in 1836 by the first parties of the Great Trek. These emigrants left Cape Colony from various motives, but all were animated by the desire to escape from British sovereignty. (See South Africa, History; and Cape Colony, History.) The leader of the first large party of emigrants was A. H. Potgieter, who concluded an agreement with Makwana, the chief of the Bataung tribe of Bechuana, ceding to the farmers the country between the Vaal and Vaal rivers. The emigrants soon came into collision with Mosilikatze, raiding parties of Zulus attacking Boer hunters who had crossed the Vaal without seeking permission from the Pretoria Government. Further conflict resulted, and in November 1837 Mosilikatze was decisively defeated by the Boers and their followers and fled northward. In the meantime another party of emigrants had settled at Thaba'tchu, where the Wesleyans had a mission station for the Barolong. The emigrants were treated with great kindness by Moroko, the chief of that tribe, and with the Barolong the Boers maintained uniformly friendly relations. In December 1836 the emigrants beyond the Orange drew up in general assembly an elementary republican form of government. After the defeat of Mosilikatze the town of Winburg (so named by the Boers in commemoration of their victory) was founded, a voortrekkers elected, and Piet Retief, one of the ablest of the voortrekkers, chosen "governor and commandant-general." The emigrants already numbered some 500 men, besides women and children and many coloured servants. Dissensions speedily arose among the emigrants, whose numbers were constantly added to, and Retief, Potgieter and other leaders crossed the Drakensberg and entered Natal. Those that remained were divided into several parties intensely jealous of each other.

Meantime a new power had arisen along the upper Orange and in the valley of the Caledon. Moshesh, a Bechuana chief of high descent, had welded together a number of scattered and broken clans which had sought refuge in that mountainous region, and had formed of them the Basuto nation. In 1833 he had welcomed as workers among his people a band of French Protestant missionaries, and as the Boer immigrants began to settle in his neighbourhood he decided to seek support from the British at the Cape. At that time the British government was not prepared to exercise effective control over the emigrants. Acting upon the advice of Dr John Philip, the superintendent of the London Missionary Society's stations in South Africa, a treaty was concluded in August 1834 with Moshesh, placing him under British protection. A similar treaty was made with the Griqua chief, Adam Kok III. (See Basutoland and Griqualand.) By these treaties, which recognized native sovereignty over large areas on which Boer farmers were settled, it was sought to keep a check on the emigrants and to protect both the natives and Cape Colony. Their effect was to precipitate collisions between all three parties. The year in which the treaty with Moshesh was made several large parties of Boers recrossed the Drakensberg into the country north of the Orange, refusing to remain in Natal when it became a British colony. During their stay there they had inflicted a severe defeat on the Zulus under Dingaan (December 1838), an event which, following on the flight of Mosilikatze, greatly strengthened the position of Moshesh, whose power became a menace to that of the emigrant farmers. Trouble first arose, however, between the Boers and the Griquas in the Philippolis district. Many of the white
farmers in this district, unlike their fellows dwelling farther north, were willing to accept British rule, and this fact induced Mr. Justice Menzies, one of the judges of Cape Colony then on circuit at Colesberg, to cross the Orange and proclaim (October 1842) the country British territory, a proclamation disallowed by the governor, Sir George Napier, who, nevertheless, maintained that the emigrant farmers were still British subjects. It was after this episode that the treaties with Adam Kok and Mosesh were negotiated. The treaties gave great offence to the Boers, who refused to acknowledge the sovereignty of the native chiefs. The majority of the white farmers in Kok's territory sent a deputation to the British commissioner in Natal, Henry Cloete, asking for equal treatment with the Griquas, and expressing the desire to come, on such terms, under British protection. Shortly afterwards hostilities between the farmers and the Griquas broke out. British troops were moved up to support the Griquas, and after a skirmish at Zwartkoppies (May 2, 1845) a new arrangement was made between Kok and Sir Peregrine Maitland, then governor of Cape Colony, virtually placing the administration of his territory in the hands of a British resident, a post filled in 1846 by Captain H. D. Warden. The place chosen by Captain (afterwards Sir) Warden as the seat of his court was known as Bloemfontein, and it subsequently became the capital of the whole country.

The volksraad at Winburg during this period continued to claim jurisdiction over the Boers living between the Orange and the Vaal and was in federation with the volksraad at Potchefstroom, which made a similar claim upon the Boers living north of the Vaal. In 1846 Major Warden occupied Winburg for a short time, and the relations between the Boers and the British were in a continual state of tension. Many of the farmers deserted Winburg for the Transvaal. Sir Harry Smith became governor of the Cape at the end of 1847. He recognized the failure of the attempt to govern on the lines of the treaties with the Griquas and Basutos, and on the 3rd of February 1848 he issued a proclamation declaring British sovereignty over the country between the Orange and the Vaal eastward to the Drakensberg. The justness of Sir Harry Smith's measures and his popularity among the Boers gained for his policy considerable support, but the republican party, whose head was Andries Pretorius (q.v.), did not submit without a struggle. They were, however, defeated by Sir Harry Smith in an engagement at Boomplaats (August 29, 1848). Thereupon Pretorius, with those most bitterly opposed to British rule, retreated across the Vaal. In March 1849 Major Warden was succeeded at Bloemfontein as civil commissioner by Mr. C. U. Stuart, but he remained British resident until July 1852. A nominated legislative council was created, a high court established, and other steps taken for the orderly government of the country, which was officially styled the Orange River Sovereignty. In October 1849 Mosesh was induced to sign a new arrangement considerably curtailing the boundaries of the Basuto reserve. The frontier towards the Sovereignty was thereafter known as the Warden line. A little later the reserves of other chieftains were precisely defined. The British Resident had, however, no force sufficient to maintain his authority, and Mosesh and all the neighbouring clans became involved in hostilities with one another and with the whites. In 1851 Mosesh joined the republican party in the Sovereignty in an invitation to Pretorius to recross the Vaal. The intervention of Pretorius resulted in the Sand River Convention of 1852, which acknowledged the independence of the Transvaal but left the status of the Sovereignty untouched. The British government (the first Russell administration), which had reluctantly agreed to the annexation of the country, had, however, already repented its decision and had resolved to abandon the Sovereignty. Lord Grey (the 3rd earl), secretary of state for the colonies, in a despatch to Sir Harry Smith dated the 21st of October 1851, declared, "The ultimate abandonment of the Orange Sovereignty should be a settled point in our policy." A meeting of representatives of all European inhabitants of the Sovereignty, elected on manhood suffrage, held at Bloemfontein in June 1852, nevertheless declared in favour of the retention of British rule. At the close of that year a settlement was at length concluded with Mosesh, which left, perhaps, that chief in a stronger position than he had hitherto been. (See BASUTOLAND: History.) There had been ministerial changes in England and the ministry then in power—that of Lord Aberdeen—adhered to the determination to withdraw from the Sovereignty. Sir George Russell Clerk was sent out in 1853 as special commissioner "for the settling and adjusting of the affairs" of the Sovereignty, and in August of that year he summoned a meeting of delegates to determine upon a form of self-government. At that time there were some 15,000 whites in the country, many of them recent emigrants from Cape Colony. There were among them numbers of farmers and tradersmen of British blood. The majority of the whites still wished for the continuance of British rule provided that it was effective and the country guarded against its enemies. The representations of their delegates, who drew up a proposed constitution retaining British control, were unsatisfactory. Sir George Clerk announced that, as the elected delegates were unwilling to take steps to form an independent government, he would enter into negotiations with other parties. "And here," writes Dr. Theal, "was seen the strange spectacle of a British commissioner addressing men who wished to be free of British control as the friendly and well-disposed inhabitants while for those who desired to remain British subjects and who claimed that protection to which they believed themselves entitled he had no sympathizing word." While the elected delegates sent two members to England to try and induce the government to alter their decision Sir George Clerk speedily came to terms with a committee formed by the republican party and presided over by Mr. J. H. Hoffman. Even before this committee met a royal proclamation had been signed (January 30, 1854) "abandoning and renouncing all dominion" in the Sovereignty. A convention recognizing the independence of the country was signed at Bloemfontein on the 23rd of February by Sir George Clerk and the republican committee, and on the 11th of March the Boer government assumed office and the republican flag was hoisted. Five days later the representatives of the elected delegates had an interview in London with the colonial secretary, the duke of Newcastle, who informed them that it was now too late to discuss the question of the retention of British rule. The colonial secretary added that it was impossible for England to supply troops to constantly advancing outposts, "especially as Cape Town and the port of Table Bay were all they really required in South Africa." In withdrawing from the Sovereignty the British government declared that it had "no alliance with any native chief or tribes to the northward of the Orange River with the exception of the Griqua chief Captain Adam Kok." Kok was not formidable in a military sense, nor could he prevent individual Griquas from alienating their lands. Eventually, in 1861, he sold his sovereign rights to the Free State for £4000 and removed with his followers to the district now known as Griqualand East. (F. R. C.)

On the abandonment of British rule representatives of the people were elected and met at Bloemfontein on the 8th of March 1854, and between that date and the 18th of April were engaged in framing a constitution. The country was declared the republic of the Orange River Colony or Orange Free State. All persons of European blood possessing a six months' residential qualification were to be granted full burgher rights. The sole legislative authority was vested in a single popularly elected chamber styled the volksraad. Executive authority was entrusted to a president elected by the burghers from a list submitted by the volksraad. The president was to be assisted by an executive council, was to hold office for five years and was eligible for re-election. The constitution was subsequently modified but remained of a liberal character. A residence of five years in the country was required before aliens could become naturalized. The first president was Mr. Hoffman, but he was accused of being too complaisant towards Mosesh and resigned, being succeeded in 1855 by Mr. J. N. Boeshof, one of
the voortrekkers, who had previously taken an active part in the affairs of Natal.

Distracted among themselves, with the formidable Basuto power on their southern and eastern flank, the troubles of the infant state were speedily added to by the action of the Transvaal Boers. Marthinus Pretorius, who had succeeded to his father's position as commandant-general of Potchefstroom, wished to bring about a confederation between the two Boer states. Peaceful overtures from Pretorius were declined, and some of his partisans in the Free State were accused of treason (February 1857). Thereupon Pretorius, aided by Paul Kruger, conducted a raid into the Free State territory. On learning of the invasion President Boshof proclaimed martial law throughout the country. The majority of the burghers rallied to his support, and on the 29th of May the two opposing forces faced one another on the banks of the Rhenoster. President Boshof not only got together some eight hundred men within the Free State, but he received offers of support from Commandant Schoeman, the Transvaal leader in the Zoutpansberg district and from Commandant Joubert of Lydenburg. Pretorius and Kruger, realizing that they would have to sustain an attack from both north and south, abandoned their enterprise. Their force, too, amounted to only some three hundred. Kruger came to Boshof's camp with a flag of truce, the "army" of Pretorius returned north and on the 2nd of June a treaty of peace was signed, each state acknowledging the absolute independence of the other. The conduct of Pretorius was stigmatized as "blameworthy." Several of the malcontents in the Free State who had joined Pretorius permanently settled in the Transvaal, and other Free Staters who had been guilty of high treason were arrested and punished. This experience did not, however, heal the party strife within the Free State. In consequence of the dissensions among the burghers President Boshof tendered his resignation in February 1858, but was for a time induced to remain in office. The difficulties of the state were at that time (1858) so great that the volksraad in December of that year passed a resolution in favour of confederation with the Cape Colony. This proposition received the strong support of Sir George Grey, then governor of Cape Colony, but his view did not commend itself to the British government, and was not adopted (see South Africa: History). In the same year the disputes between the Basutos and the Boers culminated in open war. Both parties laid claims to land beyond the Warden line, and each party had taken possession of what it could, the Basutos being also expert cattle-lifters. In war the advantage rested with the Basutos; thereupon the Free State appealed to Sir George Grey, who induced Moshesh to come to terms. On the 15th of October 1858 a treaty was signed defining anew the boundary. The peace was nominal only, while the burghers were also involved in disputes with other tribes. Mr. Boshof again tendered his resignation (February 1859) and retired to Natal. Many of the burghers would have at this time welcomed union with the Transvaal, but learning from Sir George Grey that such a union would nullify the conventions of 1852 and 1854 and necessitate the reorganization of the Free State, turned their attention towards the native tribes north of the Orange and Vaal rivers, the project dropped. Commandant Pretorius was, however, elected president in place of Mr. Boshof. Though unable to effect a durable peace with the Basutos, or to realize his ambition for the creation of one powerful Boer republic, Pretorius saw the Free State begin to grow in strength. The fertile district of Bethulie as well as Adam Kok's territory was acquired, and there was a considerable increase in the white population. The burghers generally, however, had not learned the need of discipline, of confidence in their elected rulers, or that to carry on a government taxes must be levied. Weary of the duties of Mr. Boshof, a thankless task, and more interested in affairs in the Transvaal than in those of the Free State, Pretorius resigned the presidency in 1863; and after an interval of seven months Mr. (afterwards Sir) John Henry Brand (q.v.), an advocate at the Cape bar, was elected president. He assumed office in February 1864. His election proved a turning-point in the history of the country, which, under his beneficent and tactful guidance, became peaceful and prosperous and, in some respects, a model state. But before peace could be established an end had to be made of the difficulties with the Basutos. Moshesh continued to menace the Free State border. Attempts at accommodation made by the governor of Cape Colony (Sir Philip Wodehouse) failed, and war between the Free State and Moshesh was renewed in 1865. The Boers gained considerable successes, and this induced Moshesh to sue for peace. The terms exacted were, however, too harsh for a nation yet unbroken to accept permanently. A treaty was signed at Thaba Bosigo in April 1866, but war again broke out in 1867, and the Free State attracted to its side a large number of adventurers from all parts of South Africa. The burghers thus reinforced gained at length a decisive victory over their great antagonist, every stronghold in Basutoland save Thaba Bosigo being stormed. Moshesh now turned in earnest to Sir Philip Wodehouse for preservation. His prayer was heeded, and in 1868 he and his country were taken under British protection. Thus the thirty years' strife between the Basutos and the Boers came to an end. The settlement of the Basuto troubles. The country lying to the north of the Orange river and west of the Caledon, formerly a part of Basutoland, was ceded to the Free State (see Basutoland). This country, some hundred miles long and nearly thirty wide, is a fertile stretch of agricultural land on the lower slopes of the Maluti mountains. It lies at an altitude of nearly 6000 ft., and is well watered by the Caledon and its tributaries. It has ever since been known as the Conquered Territory, and it forms to-day one of the richest corn-growing districts in South Africa. A year after the addition of the Conquered Territory to the state another boundary dispute was settled by the arbitration of Mr. Keate, lieutenant-governor of Natal. By the Sand River Convention independence had been granted to the Boers living "north of the Vaal," and the dispute turned on the question as to what stream constituted the true upper course of that river. Mr. Keate decided (Feb. 19, 1870) against the Free State view and fixed the Klip river as the dividing line, the Transvaal thus securing the Wakkerstroom and adjacent districts.

The Basutoland difficulties were no sooner arranged than the Free Staters found themselves confronted with a serious difficulty on their western border. In the years 1870-1871 a large number of diggers had settled on the diamond fields near the junction of the Vaal and Orange rivers, which were situated in part on land claimed by the Griqua chief Nicholas Waterboer and by the Free State. The Free State established a temporary government over the diamond fields, but the administration of this body was satisfactory neither to the Free State nor to the diggers. At this juncture Waterboer offered to place the territory under the administration of Queen Victoria. The offer was accepted, and on the 27th of October 1871 the district, together with some of the adjacent territory to which it was considered that the Transvaal should be proclaimed, under the name of Griqualand West, British territory. Waterboer's claims were based on the treaty concluded by his father with the British in 1834, and on various arrangements with the Kok chiefs; the Free State based its claim on its purchase of Adam Kok's sovereign rights and on long occupation. The difference between proprietorship and sovereignty was confused or ignored. That Waterboer exercised no authority in the disputed district was admitted. When the British annexation took place a party in the volksraad wished to go to war with Britain, but the wiser counsels of President Brand prevailed. The Free State, however, did not abandon its claims. The matter involved no little irritation between the parties concerned until July 1876. It was then disposed of by the 4th earl of Carnarvon, at that time secretary of state for the colonies, who granted to the Free State £90,000 "in full satisfaction of all claims which it may possess to Griqualand West." Lord Carnarvon declined to entertain the proposal made by Mr. Brand that the territory
should be given up by Great Britain. One thing at least is certain with regard to the diamond fields—they were the means of restoring the credit and prosperity of the Free State. In the opinion, moreover, of Dr Thel, who has written the history of the Boer Republics and has been a consistent supporter of the Boers, the annexation of Griqualand West was probably in the best interests of the Free State. “There was,” he states, “no alternative from British sovereignty other than an independent diamond field republic.”

At this time, largely owing to the exhausting struggle with the Basutos, the Free State Boers, like their Transvaal neighbours, had drifted into financial straits. A paper currency had been instituted, and the notes—currently known as “bluebacks”—soon dropped to less than half their nominal value. Commerce was largely carried on by barter, and many cases of bankruptcy occurred in the state. But as British annexation in 1877 saved the Transvaal from bankruptcy, so did the influent of British and other immigrants to the diamond fields, in the early ‘seventies, restore public credit and individual prosperity to the Boers of the Free State. The diamond fields offered a ready market for stock and other agricultural produce. Money flowed into the pockets of the farmers. Public credit was restored. “Bluebacks” recovered par value, and were called in and redeemed by the government. Valuable diamond mines were also discovered within the Free State, of which the one at Jagersfontein is the richest. Capital from Kimberley and London was soon provided with which to work them.

The relations between the British and the Free State, after the question of the boundary was once settled, remained perfectly amicable down to the outbreak of the Boer War in 1899. From 1870 onward the history of the state was one of quiet, steady progress. At the time of the first annexation of the Transvaal the Free State declined Lord Carnarvon’s invitation to federate with the other South African communities. In 1880, when a rising of the Boers in the Transvaal was triumphant, President Brand showed every desire to avert the conflict. He suggested that Sir Henry de Villiers, Chief Justice of Cape Colony, should be sent into the Transvaal to endeavour to gauge the true state of affairs in that country. This suggestion was not acted upon, but when war broke out between the Transvaal and the Free State, Brand declined to take any part in the struggle. In spite of the neutral attitude taken by their government a number of the Free State Boers, living in the northern part of the country, went to the Transvaal and joined their brethren then in arms against the British. This fact was not allowed to influence the friendly relations between the Free State and Great Britain. In 1888 Sir John Brand died. In him the Boers, not only in the Free State but in the whole of South Africa, lost one of the most enlightened and most upright rulers and leaders they have ever had. He realized the disinterested aims pursued by the British government, without always approving its methods. Though he had thrown the weight of his influence against Lord Carnarvon’s federation scheme Brand disapproved racial rivalries.

During the period of Brand’s presidency a great change, both political and economic, had come over South Africa. The renewal of the policy of British expansion had been answered by the formation of the Afrikander Bond, which represented the racial aspirations of the Dutch-speaking people, and had active branches in the Free State. This alteration in the political outlook was accompanied, and in part occasioned, by economic changes of great significance. The development of the diamond mines and of the gold and coal industries—which of Brand saw the beginning—had far-reaching consequences, bringing the Boer republics into vital contact with the new industrial era. The Free Staters, under Brand’s rule, had shown considerable ability to adapt their policy to meet the altered situation. In 1889 an agreement was come to between the Free State and the Cape Colony, by which the latter were empowered to extend, at their own cost, their railway system to Bloemfontein. The Free State retained the right to purchase this extension at cost price, a right they exercised after the Jameson Raid.

Having accepted the assistance of the Cape government in constructing its railway, the state also in 1889 entered into a Customs Union Convention with them. The convention was the outcome of a conference held at Cape Town in 1888, at which delegates from Natal, the Free State and the Colony attended. Natal at this time had not seen its way to entering the Customs Union, but did so at a later date.

In January 1889 Mr. F. W. Reitz was elected president of the Free State. His accession to the presidency marked the beginning of a new and disastrous line of policy in the external affairs of the country. Mr. Reitz had no sooner got into office than a meeting was arranged with Mr. Kruger, president of the Transvaal, at which various terms of an agreement dealing with the railroads, terms of a treaty of amity and commerce and what was called a political treaty, were discussed and decided upon. The political treaty referred in general terms to a federal union between the Transvaal and the Free State, and bound each of them to help the other, whenever the independence of either should be assailed or threatened from without, unless the state so called upon for assistance should be able to show the injustice of the cause of quarrel in which the other state had engaged. While thus committed to a dangerous alliance with its northern neighbour no change was made in internal administration. The Free State, in fact, from its geographical position reaped the benefits without incurring the anxieties consequent on the settlement of a large uitlander population on the Rand. The state, however, became increasingly identified with the reactionary party in the Transvaal. In 1895 the volksraad passed a resolution, in which they declared their readiness to entertain a proposition from the Transvaal in favour of some sort of federal union. In the same year Mr. Reitz retired from the presidency of the Free State, and was succeeded in February 1896 by M. T. Steyn (q.v.), a Judge of the High Court. In 1896 President Steyn visited Pretoria, where he received an ovation as the probable future president of the Union. A further offensive and defensive alliance between the two Republics was then entered into, under which the Free State took up arms on the outbreak of hostilities with the Transvaal in 1899.

In 1897 President Kruger, bent on still further cementing the union with the Free State, visited Bloemfontein. It was on this occasion that President Kruger, referring to the London Convention, spoke of Queen Victoria as a kwaajé vrou, an expression which caused a good deal of offence in England at the time, but which, to any one familiar with the homely phraseology of the Boers, obviously was not meant by President Kruger as insulting.

In order to understand the attitude which the Free State took at this time in relation to the Transvaal, it is necessary to review the history of Mr. Reitz from an earlier date. Previously to his becoming president of the Free State he had acted as its Chief Justice, and still earlier in life he had practised as an advocate in Cape Colony. In 1881 Mr. Reitz had joined in conjunction with Mr. Steyn, and at the influence of a clever German named Borckenhausen, the editor of the Bloemfontein Express. These three men were principally responsible for the formation of the Afrikander Bond (see CAPE COLONY: History). From 1881 onwards they cherished the idea of an independent South Africa. Brand had been far too sagacious to be led away by this pseudo-nationalist dream, and did his utmost to discountenance the Bond. At the same time his policy was guided by a sincere patriotism, which looked to the true prosperity of the Free State as well as to that of the whole of South Africa. From his death may be dated the disastrous line of policy which led to the extinction of the state as a republic. The one prominent member of the volksraad who inherited the traditions and enlightened views of President Brand was Mr. (Afterwards Sir) John G. Fraser. Mr. Fraser, who was an unsuccessful candidate for the presidency in 1896, was the son of a Presbyterian minister, who had acted as a minister in the Dutch Reformed Church since the middle of the century. He grew up in the country of his father’s adoption, and he consistently warned the Free State of the inevitable
result—the loss of independence—which must follow their mischievous policy in being led by the Transvaal. The mass of Boers in the Free State, seduced by a belief in Great Britain's weakness, paid no heed to his remonstrances. Mr Fraser lived to see the fulfilment of these prophecies. After the British occupation of Bloemfontein he cast in his lot with the Imperial Government, realizing that it had fought for those very principles which President Brand and he had laboured for in bygone years.

On entering Bloemfontein in 1900 the British obtained possession of certain state papers which contained records of negotiations between the Transvaal and the Orange Free State. The evidence contained in these state records so clearly marks the difference between the policy of Mr Kruger and the pacific, commercial policy of President Brand and his followers, that the documents call for careful consideration. From these papers it was found that, in 1887, two secret conferences had taken place between representatives of the Republics, dealing with various political and economical questions. At the first of these conferences, held in Pretoria, the object of the Free State deputies was to arrange a general treaty of amity and commerce which would knit the states more closely together and to come to some agreement with reference to the scheme for building a railway across the Free State from the Cape, to connect with a farther extension in the Transvaal to Pretoria. The deputation also urged the Transvaal to join the South African Customs Union. Both of these suggestions were strongly disapproved by Mr Kruger, inasmuch as they meant knitting together the Boer republics and the British possessions, instead of merely bringing the Free State into complete dependency on the Transvaal. From the minutes of this conference it is clear that the two deputations were practically at cross purposes. In the minds of President Kruger and his immediate followers one idea was dominant, that of ousting and keeping out at all costs British influence and interests. On the part of the Free State there was obviously a genuine desire to further the best interests of the state, together with the general prosperity of the whole of South Africa. In President Kruger's eyes British trade meant ruin; he desired to keep it out of the Republic at all costs, and he begged the Free State to delay the construction of their railway until the Delagoa Bay line was completed. He said, "Delagoa is a life or death question for us. Help us: if you hook on to the Colony you cut our throat . . . How can our state exist without the Delagoa railway? Keep free." With regard to the Customs Union, President Kruger was equally emphatic; he begged the Free State to steer clear of it. "Customs Unions," he said, "are made between equal states with equal access to harbours. We are striving to settle the question of our own harbour peacefully. The English will only use their position to swindle the Transvaal of its proper receipts." In response, Mr Fraser, one of the Free State delegates, remarked that a harbour requires forts, soldiers, ships and sailors to man them, or else it would be at the mercy of the first gunboat that happened to assault it. President Kruger replied that once the Transvaal had a harbour foreign powers would intervene. Mr Wolmarans was as emphatic as President Kruger. "Wait a few years. . . You know our sensitiveness! . . We cannot for a moment consider peace . . . We have to protect ourselves; the Colony would destroy us. It is not the Dutch there we are fighting against. Time shall show what we mean to do with them; for the present we must keep them off."

The result of this conference was a secret session of the Transvaal volksraad and the proposition of a secret treaty with the Free State, by which each state should bind itself not to build railways to its frontier without the consent of the other, the eastern and northern frontiers of the Transvaal being excepted. The railway from Pretoria to Bloemfontein was to be proceeded with; neither party was to enter the Customs Union without the consent of the other. The Transvaal was to pay £20,000 annually to the Free State for loss incurred for not having the railway to Cape Colony. Such a treaty as the one proposed would simply have enslaved the Free State to the Transvaal, and it was rejected by the Free State volksraad. President Kruger determined on a still more active measure, and proceeded with Dr Leyds to interview President Brand at Bloemfontein. A series of meetings took place in October of the same year (1887). President Brand opened the proceedings by proposing a treaty of friendship and free trade between the two Republics, in which a number of useful and practically provision was set forth. President Kruger, however, soon brushed these propositions aside, and responded by stating that, in consideration of the common enemy and the dangers which threatened the Republic, an offensive and defensive alliance must be preliminary to any closer union. To this Brand rejoined that, as far as the offensive was concerned, he did not desire to be a party to attacking any one, and as for the defensive, where was the pressing danger of the enemy which Kruger feared? The Free State was on terms of friendship with its neighbours, nor (added Brand) would the Transvaal have need for such an alliance as the one proposed if its policy would only remain peaceful and conciliatory. At a later date in the conference (see TRANSVAAL) President Brand apparently changed his policy, and himself drafted a constitution resembling that of the United States. This constitution appears to have been modelled on terms a great deal too liberal and enlightened to please Mr Kruger, whose one idea was to have at his command the armed forces of the Free State when he should require them, and who pressed for an offensive and defensive alliance. Brand refused to allow the Free State to be committed to a suicidal treaty, or dragged into any wild policy which the Transvaal might deem it expedient to adopt. The result of the whole conference was that Kruger returned to Pretoria completely baffled, and for a time the Free State was saved from being a party to the fatal policy into which others subsequently drew it. Independent power of action was retained by Brand for the Free State in both the railway and Customs Union questions.

After Sir John Brand's death, as already stated, a series of agreements and measures gradually subordinated Free State interests to the mistaken ambition and narrow views of the Transvaal. The influence which the Kruger party had obtained in the Free State was evidenced by the presidential election in 1896, when Mr Steyn received forty-one votes against nineteen cast for Mr Fraser. That this election should have taken place immediately after the Jameson Raid probably increased Mr Steyn's majority. Underlying the new policy adopted by the Free State was the belief held, if not by President Steyn himself, at least by his followers, that the two republics combined would be more than a match for the power of Great Britain should hostilities occur.

In December 1897 the Free State revised its constitution in reference to the franchise law, and the period of residence necessary to obtain naturalization was reduced from five to three years. The oath of allegiance to the state was alone required, and no renunciation of nationality was insisted upon. In 1898 the Free State also acquiesced in the new convention arranged with regard to the Customs Union between the Cape Colony, Natal, Basutoland and the Bechuana Land Protectorate. These measures suggest that a slight reaction against the extreme policy of President Kruger had set in. But events were moving fast in the Transvaal, and matters had proceeded too far for the Free State to turn back. In May 1899 President Steyn suggested the conference at Bloemfontein between President Kruger and Sir Alfred Milner, but this act, if it expressed a genuine desire for reconciliation, was too late. President Kruger had got the Free State ensnared in his meshes. The Free Staters were practically bound, under the offensive and defensive alliance, in case hostilities arose with Great Britain, either to denounce the policy to which they had so unwisely been secretly party, or to throw in their lot with the Transvaal. War occurred, and they accepted the inevitable consequence. For President Steyn and the Free State of 1899, in the light of the negotiations we have recorded, neutrality was impossible. A resolution was passed by the volksraad on the 27th of September declaring that the state would observe its obligations to the Transvaal whatever might happen. Before war had actually
broken out the Free State began to expel British subjects, and the very first act of war was committed by Free State Boers, who, on the 12th of October, seized a train upon the border belonging to Natal. The events of the war are given elsewhere (see Transvaal: History).

After the surrender of Cronje at Paardeberg on the 27th of February 1900 Bloemfontein was occupied by the British troops under Lord Roberts (March 15th), and on the 28th of May a proclamation was issued annexing the Free State to the British dominions under the title of Orange River Colony. For nearly two years longer the burghers kept the field under Christian de Wet (q.v.), and other leaders, but by the articles of peace signed on the 31st of May 1902 British sovereignty was acknowledged. A civil administration of the colony was established early in 1901 with Sir Alfred Milner as governor. Major (afterwards Sir) H. J. Goold-Adams was appointed lieutenant-governor, Milner being governor also of the Transvaal, which country claimed most of his attention. A nominated legislative council was established in June 1902 of which Sir John Fraser and a number of other prominent ex-burghers became unofficial members. The railways and constabulary of the two colonies were (1903) placed under an inter-colonial council; active measures were taken for the repatriation of the prisoners of war and the residents in the concentration camps, and in every direction vigorous and successful efforts were made to repair the ravages of the war. Over £4,000,000 was spent by the British government in Orange Colony alone on these objects. At the same time efforts were made, with a fair measure of success, to strengthen the British element in the country by means of land settlements. Special attention was also devoted to the development of the resources of the country by building new lines of railway traversing the fertile south-eastern districts and connecting Bloemfontein with Natal and with Kimberley. The educational system was reorganized and greatly improved.

To a certain extent the leading ex-burghers co-operated with the administration in the work of reconstruction. The loss of their independence was, however, felt bitterly by the Boers, and the attitude assumed by the majority was highly critical of the work of the government. Having recovered from the worst effects of the war the Boers, both in the Transvaal and Orange Colony, began in 1904 to make organized efforts to regain their political ascendancy, and to bring pressure on the government in respect to compensation, repatriation, the position of the Dutch language, education and other subjects on which they alleged unfair treatment. This agitation, as far as the Orange River Colony was concerned, coincided with the return to South Africa of ex-President Steyn. Mr Steyn had gone to Europe at the close of the war and did not take the oath of allegiance to the British Crown until the autumn of 1904. A congress of ex-burghers was held at Brandfort in December, 1904, when among other resolutions one demanding the granting of self-government to the colony was passed. This was followed in July 1905 by a conference at Bloemfontein, when it was resolved to form a national union. This organization, known as the Oranje Unie, was formally constituted in May 1906, but had been in existence for some months previously. A similar organization, called Het Volk, had been formed by the Transvaal Boers in January 1905. Both unions had constitutions almost identical with that of the Afrikander Bond, and their aims were similar—to secure the triumph of Boer ideals in state and society. Of the Oranje Unie Mr Abraham Fischer became chairman, other prominent members being Messrs Hertzog, C. de Wet and Steyn. Mr Fischer, the leader of the party, was one of the ablest statesmen on the Boer side in the pre-war period. He was originally an attorney in Cape Colony and had joined the Free State bar in 1875. He became vice-president of the volksraad in 1880, and a member of the executive council of the state in 1886. He was one of the most trusted counsellors of Presidents Steyn and Kruger, and the ultimatum sent to the British on the eve of hostilities was recast by him. While the war was in progress he went to Europe to seek support for the Boer cause. He returned to South Africa early in 1903 and was admitted to the bar of the Orange Colony.

A counter-organization was formed by the ex-burghers who had whole-heartedly accepted the new order of things. They took the title of the Constitutional party, and Sir John Fraser was chosen as chairman. In Bloemfontein the Constitutionalists had a strong following; elsewhere their supporters were numerically weak. It was noteworthy that the programmes of the two parties were very similar, the real difference between them being the attitude with which they regarded the British connexion. While the ideal of the Unie was an Afrikander state, the Constitutionalists desired the perfect equality of both white races.

The advent of a Liberal administration under Sir Henry Campbell-Bannerman in Great Britain in December 1905 completely altered the political situation in the late Boer states. The previous (Conservative) government had in March 1905 made public a form of representative government, intended to lead up to self-government for the Transvaal, and had intimated that a similar constitution would be subsequently conferred on the Orange Colony. The Campbell-Bannerman administration decided to do without this intermediary step in both colonies. In April 1906 a committee, under the chairmanship of Sir J. West-Ridgeway, was sent to South Africa to inquire into and report upon various questions regarding the basis of the franchise, single-member constituencies and kindred matters. There was in the Orange Colony a considerable body of opinion that the party system of government should be avoided, and that the executive should consist of three members elected by the single representative chamber it was desired to obtain, and three members nominated by the governor—in short, what was desired was a restoration as far as possible of the old Free State constitution. These views were laid before the committee on their visit to Bloemfontein in June 1906. When, however, the outline of the new constitu- tional plan for the Transvaal was promulgated (1906) it was found that the British government had decided on a parliamentary plan which would have the inevitable and fully foreseen effect of placing the country in the power of the Boer majority. It was not until the 1st of July 1907 that the letters-patent conferring self-government on the colony were promulgated, the election for the legislative assembly taking place in November following. They resulted in the return of 20 members of the Oranje Unie, 5 Constitutionalists and 4 Independents. The Constitutionalists won four of the five seats allotted to Bloemfontein, Sir John Fraser being among those returned. Following the elections the governor, Sir Hamilton Goold-Adams, sent for Mr Fischer, who formed a ministry, his colleagues being ex-General J. B. M. Hertzog, attorney-general and director of education; Dr A. E. W. Ramsbottom, treasurer; Christian de Wet, minister of agriculture, and Mr C. H. Wessels, minister of public works, &c. Mr Fischer, besides the premiership, held the portfolio of colonial secretary. The ministry took office on 27th of November. Of the members of the first legislative council five were supporters of the Oranje Unie and five were regarded as Constitutionalists, the eleventh member holding the balance.

The responsible government entered upon its task in favourable conditions. Despite the many obstacles it had to meet, including drought, commercial depression and the hostility of many of the ex-burghers, the crown colony administration had achieved remarkable results. During each of its seven years of existence there had been a surplus of revenue over expenditure, despite the fact that taxation had not materially increased, save in respect to mining, which did not affect the general population. Custom duties were about the same as in 1898, but railway rates were materially lower and many new lines had been opened. The educational system had been placed on a sound basis. Departments of agriculture, mining, health and native affairs were organized, and the civil service rendered thoroughly efficient. A substantial cash balance was left in the treasury for the use of the new government. Over 700 families had been settled on the land and thus an additional source of strength provided for the state. The first parliament under the new
constitution met on the 18th of December 1907, when it was announced that the Transvaal and Orange Colony had each given notice of the termination of the intercolonial council with the intention of each colony to gain individual control of its railways and constabulary.

After a two days' session the legislature was prorogued until May 1908, when the chief measure submitted by the government was an education bill designed to foster the knowledge of the Dutch language. This measure became law (see above § Education). Parliament also passed a measure granting ex-President Steyn a pension of £1,000 a year and ex-President Reitz a pension of £500. In view of the dissolution of the intercolonial council a convention was signed at Pretoria on the 29th of May which made provision for the division of the common property, rights and liabilities of the Orange Colony and the Transvaal in respect to the railways and constabulary, and established for four years a joint board to continue the administration of the railway systems of the two colonies. The Orange Colony assumed responsibility for £7,700,000 of the guaranteed loan of £15,000,000 of 1903 (see Transvaal: Finance). The colony took part during this month in an inter-state conference which met at Pretoria and Cape Town, and determined to renew the existing customs convention and to make no alteration in railway rates. The decisions were the result of an agreement to bring before the parliaments of the various colonies a resolution advocating the closer union of the South African states and the appointment of delegates to a national convention to frame a draft constitution.

In this convention Mr Steyn took a leading and conciliatory part, and subsequently the Orange River legislature agreed to the terms drawn up by the convention for the unification of the four self-governing colonies. Under the imperial act by which unification was established (May 31, 1910) the colony entered the union under the style of the Free State Province. (For the union movement, see South Africa: History.) Mr Fischer and General Hertzog became members of the first union ministry while Dr A. E. W. Ramsbottom, formerly colonial treasurer, became the first administrator of the Free State as a province of the union.

The period during which the province had been a self-governing colony had been one of steady progress in most directions, but was greatly embittered by the educational policy pursued by General Hertzog. From the date of the passing of the education act in the middle of 1908 until the absorption of the colony into the union, General Hertzog so administered the provisions of the act regarding the media of instruction as to compel every European child to receive instruction in every subject partly in the medium of Dutch. This policy of compulsory bilingualism was persisted in despite the vehement protests of the English-speaking community, and of the desire of many Dutch burghers that the medium of instruction for their children should be English. Attempts to adjust the difficulty were made and a conference on the subject was held at Bloemfontein in November 1909. It was fruitless, and in March 1910 Mr Hugh Gunn (director of education since 1904) resigned. The action of General Hertzog had the support of his colleagues and of Mr Steyn and kept alive the racial spirit. Failing to obtain redress the English-speaking section of the community proceeded to open separate schools, the terms of the act of union leaving the management of elementary education to the provincial council.

ORANGEMEN, members of the Orange Society, an association of Irish Protestants, originating and chiefly flourishing in Ulster, but with ramifications in other parts of the United Kingdom, and in the British colonies. Orangemen derive their name from King William III. (Prince of Orange). They are enrolled in lodges in the ordinary form of secret societies. Their toasts, about which there is no concealment, indicate the spirit of the Orangemen. The commonest form is "the glorious, pious and immortal memory of the great and good King William, who saved us from popery, slavery, knavery, brass money and wooden shoes," with grotesque or truculent additions according to the orator's taste. The brass money refers to James II's finance, and the wooden shoes to his French allies. The final words are often "a fig for the bishop of Cork," in allusion to Dr Peter Browne, who, in 1715, wrote cogently against the practice of toasting the dead. Orangemen are fond of beating drums and flouting flags with the legend "no surrender," in allusion to Londonderry. Orangism is essentially political. Its original object was the maintenance of Protestant ascendency, and that spirit still survives. The first regular lodges were founded in 1795, but the system existed earlier. The Brunswick club, founded to oppose Catholic emancipation, were sprung from the original Orange tree. The orange flowers of the Litium bulbiferum are worn in Ulster on the 1st and 12th July, the anniversaries of the Boyne and Aughrim. Another great day is the 4th of November, when William III. landed in Torbay.

ORANG-UTAN ("man of the woods"), the Malay name of the giant red man-like ape of Borneo and Sumatra, known to the Dyaks as the misas, and to most naturalists as Simia satyrs. The red, or brownish-red, colour of the long and coarse hair at once distinguishes the orang-utan from the African apes; a further point of distinction being the excessive length of the arms, which are of such proportions that the animal when in the upright posture (which it seldom voluntarily assumes) can rest on its bent knuckles. Very characteristic of the old males, which may stand as much as 5½ ft. in height, is the lateral expansion of the cheeks, owing to a kind of warty growth, thus producing an extraordinarily broad and flattened type of face. This feature is also characteristic of all the males of the species, and is apparently a feature of racial value. Another peculiarity of the males is the presence of a huge throat-sac or pouch on the front of the throat and chest, which may extend even to the arm-pits; although present in females, it does not reach nearly the same dimensions in that sex. More than half-a-dozen separate races of orang-utan are recognized in Borneo, where, however, they do not appear to be restricted to separate localities. In Sumatra the Deli and Langkat districts is inhabited by S. satyrs delenis and Abong by S. s. abongensis. In Borneo the red ape inhabits the swampy forest-tract at the foot of the mountains. In confinement these apes (of which adult specimens have been exhibited in Calcutta) appear very slow and deliberate in their movements; but in their native forests they swing themselves from branch to branch and from tree to tree as fast as a man can walk on the ground beneath. They construct platforms of boughs in the trees, which are used as sleeping-places, and apparently occupied for several nights in succession. Jack-fruit or durian, the tough spiny hide of which is torn open with their strong fingers, forms the chief food of orang-utans, which also consume the luscious mangustin and other fruits. (See PRIMATES.)

ORANJENBAUM, a town of European Russia, in the government of St Petersburg, lying 100 ft. above the sea on the south
coast of the Gulf of Finlan, opposite Kronstadt. Pop. (1807) 5,333. It is well known for its imperial palace and as a summer resort for the inhabitants of St Petersburg, from which it is 25 m. W. by rail. In 1714, Minskhoiv, to whom the site was presented by Peter the Great, erected for himself the country-seat of Oranienbaum; but confiscated, like the rest of his estates, in 1727, it became an imperial residence. In 1743, the empress Elizabeth assigned the place to Peter III., who built there a castle, Peterstadt (now destroyed), for his Holstein soldiers.

ORAOIS, an aboriginal people of Bengal. They call themselves Kurukh, and are sometimes also known as Dhangars. Their home is in Ranchi district and there are communities in the Chota Nagpur states and Palamau, where else they have scattered settlements, e.g. in Jalpaiguri and the Darjeeling Terai, whither they have gone to work in the tea-gardens. They number upwards of three quarters of a million. According to their traditions the tribe migrated from the west coast of India. The Oraons are a small race (average 5 ft. 2 in.); the colour of the hair is dark brown, but some are as light as Hindus. They are heavy-jawed, with large mouths, thick lips and projecting teeth. They reverence the sun, and acknowledge a supreme god, Dharmi or Dharmest, the holy one, who is perfectly pure, but whose beneficent designs are thwarted by evil spirits. They burn their dead, and the urn with the ashes is suspended outside the deceased's hut to await the period of the year especially set apart for burials. The language is harsh and guttural, having much connexion with Tamil. In 1901 the total number of speakers of Kurukh or Oraon in all India was nearly 600,000.

ORATORIO, the name given to a form of religious music with chorus, solo voices and instruments, independent or at least separable from the liturgy, and on a larger scale than the cantata (q.v.). Its early history is involved in that of opera (see Arias and Operas), though there is a more definite interest in its antecedents. The term is supposed, with good reason, to be derived from the fact that St Filippo Neri's Oratory was the place for which Aminuccia's setting of the Landi Spirituali were written; and the custom of interspersing these hymns among liturgical or other forms of the recitation of a Biblical story is certainly one of several sources to which the idea of modern oratorio may be traced. Further claim to the "invention" of the oratorio cannot be given to Aminuccia. A more ancient source is the use of incidental music in miracle-plays and in such medieval dramatic processions as the 12th-century Prose de L'An, which, on the 1st of January celebrated at Beauvais the Flight into Egypt. But the most ancient origin of all has hardly been duly brought into line, although it is the only form that led to classically artistic results before the time of Bach. This is the Roman Catholic rite of reciting, during Holy Week, the story of the Passion according to the Four Gospels, in such a manner that the words of the Evangelist are sung in Gregorian tones by a tenor, all directly quoted utterances are sung by voices appropriate to the speakers, and the responsa taurae ut the whole body of disciples (e.g. "Lord, is it I?") and of crowds, are sung by a chorus. The only portion of this scheme that concerned composers was the responsa taurae, to which it was optional to add polyphonic settings of the Seven Last Words or other special utterances of the Saviour. The narrative and the parts of single speakers were sung in the Gregorian tones appointed in the liturgy. Thus the settings of the Passions by Victoria and Soriano represent, in a very simple form, a perfect solution to the art problem of oratorio, as that problem presented itself to an age in which "dramatic music," or even "epic music," would have been a contradiction in terms. It has been aptly said that the object of the composer in setting such words as "Crucify Him" was not to express the feelings of an infuriated crowd, but rather to express the contrition of devout Christians telling the story; though this view must be admitted to be, like the 18th-century music itself, decidedly more modern than the quaintly dramatic traditional methods of performance. As an art-form this early Passion-music owes its perfection primarily to the church. The liturgy gives body to all the art-forms of the 18th-century church music, and it is for the composer to spiritualize or debase them by his style.

With the monodic revolution at the beginning of the 17th century the history of oratorio as an art-form controlled by composers has its real beginning. There is nothing but its religious subject to distinguish the first oratorio from the first opera; and so Emilio del Cavalierre's Rappresentazione di anima e di corpo (1600) is in no respect outside the line of early attempts at dramatic music. In the course of the 17th century the differentiation between opera and oratorio increased, but not systematically. The gradual revival of choral art found its best opportunity in the treatment of sacred subjects; not only because it was with such subjects that the greatest 17th-century voices were most associated, but also because these subjects tended to encourage such vestiges of dramatic realism as had not been already suppressed by the aria form. This arose as a concession to the desire musical necessity and to the growing vanity of singers, and it speedily became almost the only possibility of keeping music alive, or at least embalmed, until the advent of Bach and Handel. The efforts of Carissimi (d. 1674) in oratorio clearly show the limited rise from the musical standards of opera that was then possible where music was emancipated from the stage. Yet in his art the corruption of church music by secular ideas is far more evident than any tendency to elevate Biblical music-drama to the dignity of church music. Normal Italian oratorio remains indistinguishable from serious Italian opera until as late as the boyhood of Mozart. Handel's La Resurrezione and Il Trionfo del Tempo contain many pieces almost simultaneously used in his operas, and they show not the slightest tendency to indulge in choral writing. Nor did Il Trionfo del Tempo become radically different from the musical masques of Acis and Galatea and Semele, when Handel at the close of his life dictated an adaptation of it to an English translation with several choral and other numbers interpolated from other works. Yet between these two versions of the same work lies more than half the history of classical oratorio. The rest lies in that specialized German art of which the text centres round the Passion and the music culminates in Bach; after which there is no very dignified connected history of the form, until the two streams, sadly slanted, and never afterwards quite pure, united in Mendelssohn.

One feature of the Reformation in Germany was that Luther was very musical. This had the curious result that, though the German Reformation was far from conservative in its attitude towards ancient liturgy, it retained almost everything which makes for musical coherence in a church service; while the English church, with all its insistence on historic continuity, so rearranged the liturgy that no possible music for an English church service can ever form a coherent whole. We are accustomed to think of German Passion-music as typically Protestant; yet the four Passions and the Historiae der Auferstehung Christi of H. Schütz (who was born in 1585, exactly a century before Bach) are as truly the descendants of Victoria's Passions as they are the ancestors of Bach's. The difference between them and the Roman Catholic Passions is, of course, eminently characteristic of the Reformation: the language is German (so that it may be "understood of the people"), and the narrative and dialogue is set to free composition instead of to forms of Gregorian chant, though it is written in a sort of Gregorian notation. Schütz's preface to the Historiae der Auferstehung Christi shows that he writes his recitative for solo voices, though he calls it Choral des Evangelium und Chor der Personen Colloquienten. The Marcus Passion is, on internal evidence, of doubtful authenticity, being later in style and quite stereotyped in its recitative. But in the other Passions, and most of all in the Auferstehung, the recitative is expressive. It was probably organized by the organ, though the Passions contain no hint of accompaniment at all. In the
Außerstehung; the Evangelist is accompanied by four viole da gamba in preference to the organ. In any case, Schütz tells us, the players are to "execute appropriate runs or passages" during the sustained chords. Apart from their remarkable dramatic force, Schütz's oratorios show another approximation to the Passion oratorio of Bach's time in ending with a non-scriptural hymn-chorus, more or less clearly based on a chorale-tune. But in the course of the work the Scriptural narrative is as uninterrupted as it is in the Roman Catholic Passions. And there is one respect in which the Außerstehung, although perhaps the richest and most advanced of all Schütz's works, is less realistic than either the Roman Passions or those of later times; namely, that single persons, other than the Evangelist, are frequently represented by more than one voice. In the case of the part of the Saviour, this might, to modern minds, seem natural as showing a reverent avoidance of impersonation; and it was not without an occasional analogy in Roman Catholic Passion-music (in the polyphonic settings of special words). But Schütz's Passions show no such convention; this feature is peculiar to the Außerstehung; and, while the three holy women and the two angels in the scene at the tomb and represented realistically, in two soprano voices, it is curious to see Mary Magdalene elsewhere always represented by two sopranos, even though Schütz remarks in his preface that "one of the two voices may be sung and the other done instrumentaliter, or, si placet, simply left out."

Shortly before Bach, Passion oratorios, not always so entitled, were represented by several remarkable and mature works of art, most notably by R. Keiser (1673-1739). Chorale-tunes, mostly in plain harmony, were freely interspersed in order that the congregation might take part in what was, after all, a musical church service for Holy Week. The feelings of devout contemplative Christians on each incident of the story were expressed in accompanied recitatives (arioso) leading to arias; and the Scriptural narrative was sung to dramatic recitative and ejaculatory chorus on the ancient Roman plan, exactly followed, even in the detail that the Evangelist was a tenor. The difference between Bach's Passions and those of his predecessors and contemporaries is simply the difference between his music and theirs. Where his chorus represents the whole body of Christendom it has as peculiar an epic power as it is dramatic where it represents with brevity and rapid climax the responsa tuaroe of the Scriptural narrative. Take, for example, the double chorus at the beginning of the Passion according to St Matthew, where one chorus calls to the other to "come and behold" what has come to pass, and the other chorus asks "whom?" "what?" "whither?" to each exhortation, until at last the two choruses join, while above all is heard, phrase by phrase, the hymn "O Lamm Gottes unschuldig." Still more powerful, indeed unapproached even in external effect by anything else in classical or modern oratorio, is the duet with chorus that follows the narrative of the betrayal. Its tremendous final outbreak in the brief indignant appeal to heaven for the vengeance of damnation on the traitor is met by the calm conclusion of the Evangelist's interrupted narrative and the overpowering tenderness of the great figured chorale ("O Menach bewein dein' Sünde gross"), which ends the first part with a call to repentance. Such contrasts might seem to be but the natural use of fine opportunities furnished by the librettist; but the composer appears to owe less to the librettist when we find that this chorale originally belonged to the Passion according to St John, where it was to follow Peter's denial of Christ. To modern ears the most striking device in the Matthew Passion is that by which the part of Christ is separated from all the rest by being accompanied with the string band, generally at a high pitch, though deepening at the most solemn moments with an effect of sublime euphony and tenderness. And a peculiarly profound and startling thought, which has not always met with the attention it deserves, is the omission of this musical halo at the words "Eli, Eli, lamma sabachthani." These points are aesthetically parallel with Wagnerian Lied-motif, though entirely different in method. (See Opera.)

In his amazing power of declamation Bach was not altogether unanticipated by Keiser; but no one before or since approached him in sustained elevation and variety of oratorio style. Analogies to the forms of Passion music may be found in many of Bach's church-cantatas; a very favourite form being the Dialogus; as, for instance, a dispute between a fearing and a trusting soul, with, perhaps, the voice of the Saviour heard from a distance; or a dialogue between Christ and the Church, on the lines of the Song of Solomon. The Christmas Oratorio, a set of six closely connected church-cantatas for performance on separate days, is treated in exactly the same way as the Passions, with a larger proportion of non-dramatic choruses expressive of the triumphant gratitude of Christendom. Many of the single church-cantatas are called oratorios. If it were not that Bach's idea of oratorio seems to be definitely connected with that of dialogue, there is really no reason in musical terminology why the B minor Mass should not be so called, for it can never have been liturgical either in a Roman Catholic or in a Protestant church. But in all respects it stands alone; and we must now return to Handel's far more heterogeneous work, which forms the staple of almost everything else that has been understood by oratorio until the most recent times.

Handel discovered and matured every possibility of oratorio as an art-form, except such as may now be brought to light by those composers with whom the influence of Wagner is not too overwhelming for them to consider how far his principles are applicable to an art unconnected with the stage. Handel shows us that a definite oratorio style may exist in many different degrees. He was evidently impressed by the German forms of Passion-music as combining the utmost dramatic interest, with the most intense contemplative devotion; and it is significant that it was after he came to England, and before his first English oratorio, that he set to music the famous poetic version of the Passion by Brokes, a version which had been adopted by all the German composers of the time, and which, with very necessary and interesting improvements of taste, was largely drawn upon by Bach for the text of his Johannes-Passion. Handel's Brokes-Passion does not appear ever to have been performed, though Bach found access to it and made a careful copy; and it is difficult to see what motive, except interest in the form, Handel had for composing it. There is an important connecting-link between Bach's solution of the problem of oratorio and the various other solutions which Handel afterwards produced so successfully. He soon discovered how many kinds of oratorio were possible. The freedom from stage restrictions admitted of subjects ranging from semi-dramatic histories, like those of Saul, Esther and Belshazzar, to cosmic schemes based exclusively on the words of the Bible, such as Isracl in Egypt and the Messiah. Between these types there is every gradation of organization; and it may be added, every gradation between sacred and secular subjects and treatment. The very name of Handel's first English oratorio, Esther, with the facts of its production as a masque and the origin of its libretto in Racine, show the transition from the stage to the church; and a really scandalous example of the converse transition may be found by any one rash enough to look for the source of some of Haman's music in the Brokes-Passion. Roughly speaking we may reduce the types of Handelian oratorio to a three: not divisible among works as wholes, but always evident here and there. Firstly, there is the semi-operatic method, in which the arias are the utterances of characters in the story, while the conception of the chorus rarely diverges from that of multitudes of actors (e.g. Athalia, Belshazzar, Saul, &c.). The second method is a more or less recognisable application of the forms of the Passion-music to other subjects, without, however, the conception of a special rôle of narrator, but (as, for instance, in "Envy, eldest born of Hell" in Saul) with the definite conception of the choruses as descriptive of the feelings of spectators rather than of actors. Handel's
audience demanded an inconvenient number of arias, most of which are clumsily accounted for by a conventional assignment to dramatic roles with a futile attempt at love-interest; which makes many of the best solos in Saul and Joshua rather absurd. The third Handelian method is that which has since become embodied in the modern type of sacred or secular cantata; a series of numbers and numbers on a subject altogether beyond the scope of dramatic narrative (as, for instance, the greater part of Solomon), and, in the case of the Messiah and Israel in Egypt, treated entirely in the words of Scripture.

After Bach and Handel the history of oratorio becomes disjointed. The rise of the sonata style, which brought life to the opera, was almost wholly bad for the oratorio; since not only did it cause a serious decline in choral art by distracting attention from that organization of texture which is essential even to mere euphony in choral writing (see Counterpoint and Contrapuntal Forms), but its dramatic power became more and more disturbing to the essentially epic treatment demanded by the conditions of oratorio. Bach and Handel (especially Handel) were as dramatic in characterization as the greatest epic poets, and were just as far removed from the theatre. Any doubt on this point is removed by the history of Handelian opera and the reforms of Gluck. But the power of later composers to rise above the standard of their predecessors in oratorio is wholly due to the fact that the oratorio-mongers depended largely on the balance between their theatrical and contemplative sensibilities. Academicism naturally mistrusted the theatre, but, in the absence of any contemplative depth behind that of a tactful asceticism, it has then and ever since made spasmocodic concessions to theatrical effect, with the intention of avoiding pedantry, and with the effect of encouraging vulgarity. Philipp Emanuel Bach's oratorios, though not permanently convincing works of art, achieved a remarkably true balance of style in the earlier days of the conflict; indeed, with judicial reduction to the size of a large cantata, Die Israeliten in der Wüste (1769) would perhaps bear survival almost better than Haydn's Tobias (1774), in spite of the superior musical value of that ambitious forerunner of The Creation and The Seasons. These two great products of Haydn's old age owe their vitality not only to Haydn's combination of contrapuntal and choral mastery with his unsurpassable freedom of movement in the sonata style, but also to his priceless rediscovery of the fact (well known to Bach, the composer of "Mein güt'ger Herr") that "God will not be angry with me for worshipping him in a cheerful manner." This is the very spirit of St Francis of Assisi, and it brings the naively realistic birds and beasts of The Creation into line with even the Bachcanalian parts of the mainly secular Seasons, and so removes Haydn from the dangers of a definitely bad taste, which began to beset Roman Catholic oratorio on the one hand, and those of no taste at all, which engulfed Protestant oratorio on the other.

From the moment when music became independent of the church, Roman Catholic religious music, liturgical or other, lost its high artistic position. Some of the technical hindrances to greatness in liturgical music after the Golden Age are mentioned in the article Mass; but the status of Roman Catholic non-liturgical religious music was from the outset lowered by the use of the vulgar tongue, since that implied a condescension to the laity, and composers could not but be affected by the assumption that oratorio belonged to a lower sphere than Latin church music. With this element of condescension came a reluctance to foster the fault of intellectual pride by criticizing pius verse on religious subjects. Weitlich, in his letter to the Breslau Court, has pointed out that the purest work of the purest author is, however, still causes educated people to strain tolerance of bad hymns to an extent which apostles of culture denounce as positively immoral; but the initial impossibility of basing a non-Latin Roman Catholic oratorio directly on the Bible would already have been detrimental to good taste in religious musical texts even if criticism were not disarmed. It must be confessed that Protestant taste (as shown in the texts of many of Bach's cantatas) was often unsurpassably bad; but in its most morbid phases its badness was mainly barbarian, and could either be ignored by composers and listeners, or easily improved away, as Bach showed in his alterations of Brockes's vile verses in the Passion according to St John. But the bad taste of the text of Beethoven's Christus am Oldeberge (The Mount of Olives, c. 1800) is ineradicable, for it represents the standpoint of writers who may be very devout and innocent, but whose purest source of sacred art has been the pictures of Guido Reni. It was one thing for Sir Joshua Reynolds to admire the wrong period of Italian art: he had his own access to great ideas; but for Beethoven's librettist, who had no such access, it was very different. The real sacred subject has no chance of penetrating through a trahison which is neither naïve nor ecclesiastical, but is simply that of a long-tolerated comfortable vulgarity. An operatic tenor represents the Saviour; an operatic soprano represents the ministering angel; and in the garden of Gethsemane the two sing an operatic duet. The music is brilliant and well worthy of Beethoven's early powers, but he afterwards greatly regretted it; and indeed its circumstances are intolerable, and the English attempt at a new libretto (Engedi, or David in the Wilderness) only substituted ineptitude for irreverence.

Schubert's wonderful fragment Lazarus (1820) suffers less from the sinnlichkeit of its text; for the music seizes on a certain genuine quality aimed at by all typical Roman Catholic religious literature, and even of a kind of romantic mysticism unexamled in Protestant oratorio. Modern literature shows this peculiar strain in Cardinal Newman's Dream of Gerontius, just as Sir Edward Elgar's setting of that poem to music of Wagnerian continuity and texture presents the only parallel discoverable later or earlier to the slightly oppressive aroma of Schubert's unique experiment. Lazarus also surprises us by a rather invertebrate continuity of flow, anticipating early Wagnerian opera; indeed, in almost every respect it is two generations ahead of its time; and, if only Schubert had finished it and allowed it to see publicity, the history of 19th-century oratorio might have become a more interesting subject than it is.

The ascendancy of Mendelssohn, as things happened, is really its main redeeming feature. Mendelssohn applied an unprecedented care and a wide general culture to the structure and criticism of his libretto (see his correspondence with Schubring, his principal helper with the texts of St Paul and Elijah), and was able to bear witness of his new-found gospel according to Bach by introducing chorales into St Paul as well as by discretion in his handling of these chorales; and, whereas he had not the strength to rescue oratorio from the slough into which it had now fallen, no less in Protestant than in Roman Catholic forms.

As the interest in Biblical themes becomes more independent of church and dogma, oratorio once more tends to become confused with Biblical opera. The singular fragrance and tenderness of the best parts of Berlioz's little masterpiece L'Enfance du Christ (put together from sections composed between 1847 and 1854) give it high artistic value; but if "oratorio" means "sacred music" Berlioz was incapable of anything of the sort; for the Christianity of his Grande Messe des morts and his Te Deum is the Christianity of Napoleon; and, if oratorio means a consistent treatment of a legend or subject in terms of musical epic, Berlioz can never fix his attention long enough to remember how he began by the time he has got half way through. Though Berlioz's essay in oratorio is not quite so irresponsible a vocal-symphonic-dramatic medley as his Romeo et Juliette and Damnation de Faust, it unmistakably marks a transition towards the complete secularization of the Bible for musical purposes. But the longcontinued prejudice in England against the representation of Biblical subjects in English has led to a similar confusion in the theory of their romantic treatment in music.

It may be noted as a curiosity that Saint-Saëns's Biblical opera, Samson et Dalila (written in 1877), after being known in England for many quiet years as an oratorio, suddenly, in 1910, was permitted by the censor of plays, under royal command, to be produced at Covent Garden for what it was intended. It may

1 Schubert's well-known cantata, Miriam's Siegesgesang, has been discussed as a small oratorio; but it is of slight artistic and no historic importance.
even be suggested that this occurred just early enough to prevent Strauss's Salome from being regarded by the British public as an oratorio.

The earliest efforts of César Franck prevented French oratorio from drifting entirely towards the stage; and meanwhile year by year Brahms's Deutsches Requiem (completed, except for one movement, in 1868) towers ever higher above all choral music since Beethoven's Mass in D, and draws us away from the semi-dramatic oratorio towards the musically perfectible form of an enlarged cantata in which a group of choral movements is concentrated on a set of religious ideas differing from liturgical forms only in free choice of text. Within the essentially non-theatrical limitations of dramatic or epic oratory, we may note the spirited new departures of Sir Charles Stanford in Eden (1891), and of Sir Hubert Parry in Judith (1888), Job (1892) and King Saul (1894), which showed that Wagnerian Leitmotifs and musical interest might well avail to produce an oratorio style standing to Mendelssohn as Wagner stands to Mozart, if musical interest be retained in the foreground. Freedom from the restrictions of the stage also means absence of the resources of the stage, so that Wagnerian Leitmotifs is no substitute for formal musical coherence when the audience has no action before its eyes. Accordingly these leaders of the English musical renaissance are by no means exclusively Wagnerian in their oratorios. A fine and typical example of their peculiar non-theatrical resources may be seen in the end of King Saul, where Parry (who, like Wagner, is his own librettist) makes the Witch of Endor foresee the battle of Gilboa, and allows her tale to become real in the telling; so that it is followed immediately by the final dirge.

(D. F. T.)

ORATORY (Lat. oratoria, sc. aors; from orare, to speak or pray), the art of speaking eloquently or in accordance with the rules of rhetoric (q.v.). From Lat. oratorium, sc. templum, a place of prayer, comes the use of the word for a small chapel or place of prayer for the use of private individuals, generally attached to a mansion and sometimes to a church. The name is also given to small chapels built to commemorate some special deliverance.

ORATORY OF ST PHILIP NERI, CONGREGATION OF THE, or ORATORIANS, a religious order consisting of a number of independent houses. The first congregation was formally organized in 1575 by the Florentine priest, Philip Neri. (See NERI, PHILIP.)

ORB, a circle or ring (Lat. orbis), hence a globe or disk or other spherical object. It is thus used, chiefly poetically, of any of the heavenly bodies, including the earth itself (Lat. orbis terrarum, or of the eye-ball or eye. The "orb," also known as the "mound" (Lat. mundus, "world"), consisting of a globe surmounted by a cross, forms part of many regalia, being a symbol of sovereignty (see REGALIA). In architecture the meaning to be attached to the word "orb" is doubtful. It is usually now taken to mean properly a blank or blind window, and thence a blank panel. If so the word represents Lat. orbis, "be of," "orphaned," fenestra orbis luminis. It is also identified with a circular basin concealing the intersection of arches in a vault.

ORBITELLO, a town of Tuscany, Italy, in the province of Grosseto, 4 m. S. by E. of Grosseto by rail, 7 ft. above sea level. Pop. (1901) 4,188 (town), 5,335 (commune). It is situated on a tongue of land projecting westward into a lagoon which is enclosed on the W. and S. by two long narrow sandy spits, and on the seaward (S.W.) side by the peninsula of Monte Argentario. A causeway connecting the town with this peninsula was built across the lagoon in 1842. On every side except the landward (E.) side the town is enclosed by an ancient terrace wall of polygonal work, and tombs have been discovered in the vicinity and even within the town itself. On the N. side of the promontory are the remains of a Roman villa partly below sea-level. The town must thus occupy an ancient site, the name of which is unknown. The town still has the bastions which the Spaniards built during the period (1557-1713) when they were masters of this corner of Italy. There is a large convict prison with which is connected another at Porto Ercole, on the east side of the peninsula. The mother house of the Passionist order crowns an eminence of Monte Argentario, now strongly fortified. The salt-water lagoon (11 sq. m. in extent) is the middle of which the town stands, abounds in white fish, sole, and eels. On the eastern edge of the Monte Argentario is an active manganese ore mine, yielding some 30,000 tons per annum.

After the fall of the Republic of Siena, when the territory of Siena passed to Tuscany, Philip II. of Spain retained Orbetello, Talamone, Monte Argentario and the island of Giannutri until 1713, under the name of the Reali Stati del Presidio. There are still many Spanish names among the inhabitants of Orbetello. In 1713 this district passed by treaty to the emperor, in 1736 to the king of the two Sicilies, in 1801 to the kingdom of Etruria, and in 1814 to the grand-duchy of Tuscany.

See G. Dennis, Cities and Cemeteries of Etruria (London, 1883), ii. 290; M. Carmichael, In Tuscany (London, 1901), 293, sqq. (T. As.)

ORBIGNY, ALCIDE DESSALINES D' (1802-1857), French palaeontologist, was born at Couréon, Loire Inférieure, on the 6th of September 1802. He was educated at La Rochelle, and there became interested in the natural history, and in particular of zoology and palaeontology. His first appointment was that of travelling naturalist for the Museum of Natural History at Paris. In the course of his duties he proceeded in 1826 to South America, and gathered much information on the natural history and ethnology, the results being embodied in his great work Voyage dans l'Amerique Meridionale (1839-1842). Meanwhile he had decided to devote his time and energies to palaeontology, and he dealt in course of time with various invertebrata from foraminifera to crinoids and mollusca. In 1840 he commenced the publication of Paléontologie Francaise, ou description des fossiles de la France, a monumental work, accompanied by figures of the species. Eight volumes were published by him dealing with Jurassic and Cretaceous invertebrata, and since his death many later volumes have been issued. (See notes by C. D. Sherborn, "On the Dates of the Paléontologie Francaise of D'Orbigny," Geol. Mag., 1899, p. 239.) Among his other works were Cours élémentaire de paléontologie et de géologie stratigraphiques (3 vols., 1849-1854), and Progrès de paléontologie et stratigraphie (2 vols. 1855-1857). D'Orbigny introduced (1852) a methodical system of nomenclature for geological formations based partly on the English terms—thus Batheronian for the Great or Bath Oolite, Bajocian from Bajocca or Bayeux in Calvados for the Inferior Oolite. Many of these names have been widely adopted, but some are too local application to be generally used. In 1853 he was appointed professor of palaeontology at the Museum of Natural History in Paris, but died four years later, on the 30th of June 1857, at Pierresite, near St Denis.

ORBILUS, PUPILLUS, a Latin grammarian of the 1st century A.D., who had a school at Rome, where the poet Horace was one of his pupils. Horace (Epistles, ii.) criticizes his old school-master and describes him as plagiosus (a fangler), and Orbillus has become proverbial as a disciplinarian pedagogue.

ORBIT (from Lat. orbis, a track, orbis, a wheel), in astronomy, the path of any body, and especially of a heavenly body, revolving round a centre of attraction. If the law of attraction is that of gravitation, the orbit is a conic section—ellipse, parabola or hyperbola—having the centre of attraction in one of its foci; and the motion takes place in accordance with Kepler's laws (see ASTRONOMY). But unless the orbit is an ellipse the body will never complete a revolution, but will recede indefinitely from the centre of motion. Elliptic orbits, and a parabolic orbit considered as the special case when the eccentricity of the ellipse is 1, are almost the only ones the astronomer has to consider, and our attention will therefore be confined to them in the present article. If the attraction of a central body is not the only force acting on the moving body, the orbit will deviate from the form of a conic section in a degree depending on the amount of the extraneous force; and the curve described may not be a re-entering curve at all, but one winding around as
to form an indefinite succession of spires. In all the cases which have yet arisen in astronomy the extraneous forces are so small with the gravitation of the central body that the orbit is approximately an ellipse, and the angle of inclination, as well as all determinations in which a high degree of precision is not necessary, are made on the hypothesis of elliptic orbits. Below are set forth the methods of determining and dealing with such orbits.

We begin by considering the laws of motion in the orbit itself, regarding the fundamental plane. At one of the nodes, say the ascending node, the body is at the longitude $\lambda$, and the mean anomaly $\Delta$ is the angle at the centre of the orbit of the body, when the line of the nodes is due south. It is the angle $\theta$ of the orbit of the body, when the line of the nodes is south of west. It is the angle $\theta$ of the orbit of the body, when the line of the nodes is south of east. It is the angle $\theta$ of the orbit of the body, when the line of the nodes is south of north. It is the angle $\theta$ of the orbit of the body, when the line of the nodes is south of south. It is the angle $\theta$ of the orbit of the body, when the line of the nodes is south of west. It is the angle $\theta$ of the orbit of the body, when the line of the nodes is south of east. It is the angle $\theta$ of the orbit of the body, when the line of the nodes is south of north. It is the angle $\theta$ of the orbit of the body, when the line of the nodes is south of south. It is the angle $\theta$ of the orbit of the body, when the line of the nodes is south of west. It is the angle $\theta$ of the orbit of the body, when the line of the nodes is south of east. It is the angle $\theta$ of the orbit of the body, when the line of the nodes is south of north. It is the angle $\theta$ of the orbit of the body, when the line of the nodes is south of south.
In the centre is Christ in majesty between kneeling figures of St Peter and St Thomas Aquinas, attended by angel musicians; on each side are standing figures of three other saints. It is a work of the greatest beauty both in colour and composition; it is painted with extreme miniature-like delicacy, and is on the whole very well preserved. This relatable is signed, "Aa'. d[ai]. mccvii Andreas Cionis de Florentia me pinxit."

Another fine altar-piece on panel by Orcagna, dated 1363, is preserved in the Cappella de' Medici, near the sacristy Sta Croce; it represents the four doctors of the Latin church. According to Vasari, Orcagna also painted some very fine frescoes in Sta Croce, similar in subjects to those attributed to him in the Campo Santo of Pisa, and full of fine portraits. These do not now exist. In the cathedral of Florence, on one of the northern piers, there hangs a nobly designed and highly finished picture on panel by Orcagna, representing S Zanobio enthroned, trampling under his feet Cruelty and Pride; at the sides are kneeling figures of SS Eugenius and Crescenti—-the whole very rich in colour. The relatable mentioned by Vasari as having been painted for the Florentine church of S Pietro Maggiore is now in the National Gallery of London. It is a richly decorative composition of the Coronation of the Virgin, between rows of saints, together with nine other subjects painted in miniature. Other paintings on panel by Orcagna were sent by the Pope to Avignon, but cannot now be traced. The frescoes he also have been destroyed, with which, according to Vasari, Orcagna was engaged on the facade of S Spigho in the Cappella de' Cresci in the church of the Servi in Florence.

2. Orcagna as a Sculptor and Architect.—In 1355 Orcagna was appointed architect to the chapel of Or San Michele in Florence. This curiously-planned building, with a large upper room over the vaulting of the lower part, has been begun by Taddeo Gaddi as a thank-offering for the cessation of the plague of 1348. It took the place of an earlier oratory designed by Arnolfo del Cambio, and was the gift of the united trade-gilds of Florence. As to the building itself, it is impossible to say how much is due to Taddeo Gaddi and how much to Orcagna, but the great marble tabernacle was wholly by Orcagna. This, in its combined splendour of architectural design, sculptured reliefs and statuettes, and mosaic enrichments, is one of the most important and beautiful works of art which even rich Italy possesses. It combines an altar, a shrine, a reredos and a baldacchino. In general form it is perhaps the purest and most gracefully designed of all specimens of Italian Gothic. It is a tall structure of white marble, with vaulted canopy and richly decorated gables and pinnacles, reaching almost to the vaulted roof. It is richly and delicately sculptured, and the gem-like colour is given by lavish enrichments of minute patterns in glass mosaic, inlaid in the white marble of the structure. It is put together with the greatest care and precision; Vasari especially notes the fact that the whole was put together without any cement, which might have stained the purity of the marble, all the parts being closely fitted together with bronze dowels. The spire-like summit of the tabernacle is surmounted by a figure of St Michael, and at a lower stage on the roof are statuettes of the apostles. The altar has a relief of Hope between panels with the Marriage of the Virgin and the Annunciation. On the right side, looking east, of the base of the tabernacle are reliefs of the Birth of the Virgin and her Presentation in the Temple; on the left, the Nativity and the Adoration of the Magi; and behind, the Presentation of Christ in the Temple, and the

The magnificent but much injured frescoes of the Last Judgment, Hell, and the Triumph of Death in the Pisan Campo Santo, described with great minute and enthusiasm by Vasari, are attributed by him to Orcagna; but internal evidence shows they are productions of the Sienese school. Crowe and Cavalcaselle attribute them to the two brothers Lorenzetti of Siena, but they have been so injured by wet, the settlement of the wall, and repeated retouchings that it is difficult to come to any clear decision as to their authorship. It appears, however, much more probable that they are the work of Bernardo Daddi.

3 Orcagna was admitted as a member of the Sculptors' Gild in 1352. His name occurs in the roll as "Andreas Cionis vocatus Arcagnolus, pictor."

1. Of this form, sometimes spelt Orcagnolo, Orcagna is a corruption.
Angel warning the Virgin to escape into Egypt. Above the last two subjects are large reliefs of the Death of the Virgin, surrounded by the apostles, and higher still her Assumption; she sits in a vesica, and is borne by angels to heaven. On the base of the Virgin's tomb is inscribed "Andrea Cionis pictor Florentinus oratorii archimagnetor exuitvs mccclix." Orcagna's own portrait is given as one of the apostles. In addition to these richly-composed subject-reliefs the whole work is adorned with many other single figures and heads of prophets, angels, and the Virtues, executed with wonderful finish and refinement. The shrine, which forms an ambry in the rederos, contains a miraculous picture of the Madonna. A fine bronze screen, with open geometrical tracery, encloses the whole. No work of sculpture in Italy is more magnificent than this wonderful tabernacle, both in general effect and in the delicate beauty of the reliefs and statuettes with which it is so lavishly enriched. It cost the enormous sum of 96,000 gold florins. Unfortunately it is very badly placed and insufficiently lighted, so that a minute examination of its beauties is a work of difficulty.

No mention is made by Vasari of Orcagna's residence in Orvieto, where he occupied for some time the post of "capomastro" to the duomo. He accepted this appointment on the 14th of June 1358 at the large salary (for that time) of 300 gold florins a year. His brother Matteo was engaged to work under him, receiving 8 florins a month. When Orcagna accepted this appointment at Orvieto he had not yet finished his work at Or San Michele, and so was obliged to make long visits to Florence, which naturally interfered with the satisfactory performance of his work for the Orvietans. The result was that on the 12th of September 1360 Orcagna, having been paid for his work up to that time, resigned the post of "capo-mastro" of the duomo, though he still remained a little longer in Orvieto to finish a large mosaic picture on the west front. When this mosaic (made of glass tesserae from Venice) was finished, he was to be unevan in surface, and not fixed securely into its cement bed. An arbitration was therefore held as to the price Orcagna was to receive for it, and he was awarded 60 gold florins.

Vasari mentions as other architectural works by Orcagna the design for the piers in the nave of the Florentine duomo, a cecca or mint, which appears not to have been carried out, and the Loggia dei Lanzi in the Piazza della Signoria. It is, however, more than doubtful whether Orcagna had any hand in this last building, a very graceful vaulted structure, with three semicircular open arches on the side and one at each end, intended to form a sheltered meeting-place for the Priori during elections and other public transactions. This loggia was ordered by the General Council of Florence in 1356, but was not actually begun till the year 1376, after Orcagna's death. The architects were Benci di Cione (possibly a brother of Orcagna) and Simon di Francesco Talenti, both men of considerable reputation in Florence. The sculptured reliefs of the seven Virtues in the spandrels of the arches of the loggia, also attributed to Orcagna by Vasari, were later still. They were designed by Angelo Gaddi (1383-1386), and were carried out by three or four different sculptors.

Pupils of Orcagna named by Vasari are Bernardo Nello, a Pisan, Tommaso di Marco, a Florentine, and, chief of all, Francesco Traini, whose grand painting on panel of St Thomas Aquinas enthroned with angels and saints, besides his feet still hang in the church for which it was painted—Sta Caterina at Pisa. Orcagna had, in addition to the two daughters mentioned above, a son named Cione, who was a painter of but little eminence. Some sonnets attributed to Orcagna are found in the "Scritti insinante dei Scrittori ch'abitarono in Firenze." They have been published by Trucchi (Poesie inedite, ii. p. 25, Prato, 1846). They are graceful in language, but rather artificial and over-elaborated.

Orcard-Orchardson.

ORCHARDSON, Sir William Quiller (1835-1910), British painter, was born in Edinburgh, where his father was engaged in business, in 1835. "Orchardson" is a variation of "Urquhartson," the name of a Highland seft settled on Loch Ness, from which the painter is descended. At the age of fifteen he was sent to the Trustees' Academy, then under the mastership of Robert Scott Luder, where he had as fellow-students most of those who afterwards shed lustre on the Scottish school of the second half of the 19th century. As a student he was not especially precocious or industrious, but his originality was distinguished by a peculiar reserve. By an unusual determination that his hand should be subded to his eye, with the result that his early things reach their own ideal as surely as those of his maturity. By the time he was twenty, Orchardson had mastered the essentials of his art, and had produced at least one picture which might be accepted as representative, a portrait of Mr John Hutchinson, the sculptor. For seven years after this he worked in Edinburgh, some of his attention being given to "black and white," his practice in which had been partly acquired at a sketch club, which included among its members Mr Hugh Cameron, Mr Peter Graham, Mr George Hay, Mr M'Taggart, Mr John Hutchinson and others. In 1862 he came to London, and established himself in 37 Fitzroy Square, where he was joined twelve months later by his friend John Pettie. The same house was afterwards inhabited by Ford Madox Brown.

The English public was not immediately attracted by Orchardson's work. It was too quiet to compete at the Royal Academy, and Pettie, Orchardson's junior by four years, stepped before him for a time, and became the most readily accepted member of the school. Orchardson confined himself to the simplest themes and designs, to the most reticent schemes of colour. Among his best pictures during the first eighteen years after his migration to London were "The Challenge," "Christopher Sly," "Queen of the Swords," "Conditional Neutrality," "Hard Hit"—perhaps the best of all—and portraits of Mr Charles Moxon, his father-in-law, and of his own wife. In all these good judgment and a refined imagination were united to a restrained but consummate technical dexterity. During these same years he made a few drawings on wood, turning to account his early facility in this mode. The period between 1862 and 1880 was one of quiet ambitions, of a characteristic insouciance, of life accepted as a thing of many-balanced interests rather than as a matter of storm and stress. In 1865 Pettie married, and the Fitzroy Square ménage was broken up. In 1868 Orchardson was elected A.R.A. In 1870 he spent the summer in Venice, travelling home in the early autumn through a France overrun by the German armies. In 1873 he married Miss Helen Moxon, and in 1877 he was elected to the full membership of the Royal Academy. In the same year he finished building a house at Westgate-on-Sea, with an open tennis-court and a studio in the garden. He was knighted in June 1907, and died in London on the 13th of April 1910.

Orchardson's wider popularity dates from 1881. To that year's Academy he sent the large "On the Board the Bellerophon," which now hangs in the Tate Gallery. Its success with the public was great and instantaneous, and for ten or twelve years Orchardson's work was more eagerly looked for at the Academy than any other. He followed up the "Bellerophon" with the still finer "Voltaire," now in the Kunsthalle at Hamburg. Technically, the "Voltaire" is, perhaps, his high-water mark. Fine both in design and colour, it is carried out with a supple dexterity of hand which has scarcely been equalled in the British school since the death of Gainsborough. The subject is not entirely happy, for it does not explain itself, but requires a previous knowledge on the part of the spectator of how Voltaire
was beaten by the servants of the Chevalier de Rohan-Cabot, and how the duc de Sully failed to avenge his guest. The painter was attracted by the opportunity it gave for effective opposition of character, line, colour and movement. The "Voltaire" was at the Academy of 1883; it was followed, in 1884, by the "Mariage de convenance," perhaps the most popular of all Orchardson's pictures; in 1885, by "The Salon of Madame Récamier"; in 1886, by "After," the sequel to the "Mariage de convenance," and "A Tender Chord," one of his most exquisite productions; in 1887, by "The First Cloud"; in 1888, by "Her Mother's Voice"; and in 1889, by "The Young Duke," a canvas on which he returned to much the same pictorial scheme as that of the "Voltaire." Subsequently he exhibited a series of pictures in which fine pictorial use was made of the furniture and costumes of the early years of the 19th century, the subjects, as a rule, being only just enough to suggest a title: "An Enigma," "A Social Eddy," "Reflections," "If music be the food of love, play on!" "Music, when sweet voices die, vibrates on the memory," "Her First Dance,"—in these, opportunities are made to introduce old harpsichords, spinets, early pianofortes, Empire chairs, sofas and tables, Aubusson carpets, short-waisted gowns, and diamond tiaras, in ornamented portraits. By such things and Orchardson's method as a painter the sympathy is close, so that the best among them, "A Tender Chord," for instance, or "Music, when sweet voices die," have a rare distinction.

As a portrait-painter Orchardson must be placed in the first class. His portraits are not numerous, but among them are a few which rise to the highest level reached by modern art. "Master Baby," a picture, connecting subject-painting with portraiture, is a masterpiece of design, colour and broad execution. "Mrs Joseph," "Mrs Ralli," "Sir Andrew Walker, Bart.," "Charles Moxon, Esq.," "Mrs Orchardson," "Conditional Neutrality" (a portrait of Orchardson's eldest son as a boy of six), "Lord Rookwood," "The Provost of Aberdeen," and, above all, "Sir Walter Gilhey, Bart.," would all deserve a place in any list of the best portraits of the 19th century. In this branch of art the "Sir Walter Gilhey" may fairly be called the painter's masterpiece, although the sumptuous full-length of the Scottish provost, in his robes, runs it closely. The scheme of colour is reticent; had the picture been exhibited at the time of the Boer War of 1900 the colour would have been called khaki; the design is simple, uniting nature to art with a rare felicity; and the likeness has been found satisfactory by the sitter's friends. The most important commission ever received by Orchardson as a portrait-painter was that for a group of Queen Victoria, with her son (afterwards King Edward VII.), grandchild, and great-grandson, to be painted on one canvas for the Royal Agricultural Society. The painter hit upon a happy notion for the bringing of the four figures together, and as time goes on and the picture slowly turns into history, its merit is likely to be better appreciated. He continued painting to the end of his life, and had three portraits ready for the Royal Academy in 1910.

Orchardson's method was that of one who worked under a creative, decorative and subjective impulse, rather than under one derived from a wish to observe and record. His affiliation is with Watteau and Gainsborough, rather than with those who would base all pictorial art on a keen eye for actuality and "values." Among French painters his pictures have excited particular admiration. (W. Ar.)

**ORCHESTRA**

(Fr. Orchestre; Ger. Kapelle, Orchester; Ital. Orchestra), in its modern acceptation (1) the place in a theatre or concert hall set apart for the musicians; (2) a carefully-balanced group of performers on strings, wind and percussion instruments adapted for playing in concert and directed by a conductor. In ancient Greece the ὀρχήστρα was the space between the auditorium and the prosenium or stage, in which were stationed the chorus and the instrumentalists. The second sense is that which is dealt with here.

A modern orchestra is composed of (1) a basis of strings—first and second violins, violas, violoncellos and double basses; (2) flutes, sometimes including a piccolo; (3) the reed contingent, consisting of two complete families, the oboes with their tenors and basses (the cor Anglais, the fagotto or bassoon and the contrabassoon or double bassoon), the clarinets with their tenor and basses (the bassett horn and the bass and pedal clarinets) with the addition sometimes of saxophones; (4) the brass wind, consisting of the horns, a group sometimes completed by the tenor and tenor-bass Wagner tubas, the trumpet or cornet, the trombones (tenor, bass and contrabass), the tubas (tenor, bass and contrabass); (5) the percussion instruments, including the kettle-drums, bells, Glockenspiel, cymbals, triangle, &c. Harps are added when required for special effects.

Although most of the instruments from the older civilizations of Egypt, Chaldea, Persia, Phoenicia and of the Semitic races were known to the ancient Greeks, their conception of music led them to discourage all imitation of their neighbours' love of orchestral effects, obtained by combining harps, lyres, guitars, tambours, double pipes and long flutes, trumpets, bagpipes, cymbals, drums, &c., playing in unison or in octaves. The Greeks only cultivated to any extent the various kinds of citharas, lyres and auloi, seldom used in concert. To the prediction of the Romans for wind instruments of all kinds, was added all throughout the Middle Ages and the modern orchestra, each of which had its prototype among the instrumentalists of the Roman Empire: the flute, oboe and clarinet, in the tibia; the trombone and trumpet in the buccina; the tubas in the tuba; and the French horn in cornu and buccina. The 4th century A.D. witnessed the downfall of the Roman drama and the debasement of instrumental music, which was placed under a ban by the Church. During the convulsions which the migrations of Goths, Vandals and Huns caused in Europe after the fall of Rome, instrumental music was preserved from absolute extinction by wandering actors and musicians turned a drift after the closing of the theatres by command of the Church. Later, as demand arose, reinforcements of instruments, instrumentalists and instrument makers filtered through the Byzantine Empire and the Christian East generally on the one side and from the Moors on the West. It is towards the dawn of the 11th century that we find the first definite indications of the status of instrumental music in Western and Central Europe. Everywhere there are the evidences, so conspicuously absent from the data of Rome, of a connection between the growing favour in which instrumental music was held, to instance only such sculptures as those of the Abbey of Boscherville in Normandy, of the portico of the Cathedral of Santiago da Compostella (12th century) with its orchestra of 24 musicians, and the full-page illuminations of Psalters representing David and his musicians and of the 24 elders in the Apocalypse.

The earliest instrumental compositions extant are certain 15th-century dances and pieces in contrapuntal style preserved in the libraries of Berlin and Munich. The late development of notation, which long remained exclusively in the hands of monks and troubadours, personally more concerned with vocal than with instrumental music, ensured the preservation of the former, while the latter was left unrecorded. Instrumental music was for centuries dependent on outcasts and outlaws, tolerated by Church and State but beyond the pale. Little was known of the construction and technique of the instruments, and their possibilities were undreamed. Nevertheless, the innate love and yearning of the people for tone-colour asserted itself with irresistible force in an art to which the necessities of the growing favour in which instrumental music was held, instance only such sculptures as those of the Abbey of Boscherville in Normandy, of the portico of the Cathedral of Santiago da Compostella (12th century) with its orchestra of 24 musicians, and the full-page illuminations of Psalters representing David and his musicians and of the 24 elders in the Apocalypse.
same century the *organistrum*, named after Hubald's *organum*, and specially constructed to reproduce it. Shortly after the introduction of the polyphony, instruments such as flutes à bec, fl Alias, cornets, cromorne, shawms, hunting horns, bagpipes, as well as lutes and bowed instruments began to be made in sizes approximately corresponding in pitch with the voice parts. It is probably to the same yearning of instrumentalists after a polyphonic ensemble, possible until the 14th century only on organs, hurdy-gurdies and bagpipes, that we owe the clavichord and clavicembalo, embodying the application of keys, respectively, to the dulcimer and the psaltery.

There are two reasons which account for the development of the brass wind proceeding more slowly. (1) These instruments, trumpets or busines, tubas and horns, were for many centuries mainly used in medieval Europe as military or hunting signal instruments, and as such the utmost required of them was a fanfare. Specimens of 14th-century tablature and 16th-century notation for the horn, for instance, show that for that instrument rhythm alone was taken into account.

(2) Whereas in most of the instruments named above the notes of the diatonic scale were either fixed or easily obtained, the acoustic principles of tubes without lateral holes and blown by means of a cup mouthpiece do allow of a diatonic scale, except for the octaves from the fundamental, made likely only in trumpets and horns, the notes of the common chord with the addition of the flattened seventh being the utmost that can be produced without the help of valves, keys or slides. These instruments were, therefore, the last to be added to the orchestra, although they were extensively used for special military, civil and religious functions and were the most highly favoured of all.

The earliest improvement in the status of the roving instrumentalists came with the rise of minstrelsy. The courts of the counts of Toulouse, Provence and Barcelona were the first to foster the art of improvising or composing songs known as *trobar* (or *trobador* in the north of France), and Count Guillaume of Poitiers (1087-1127) is said to have been the first troubadour. This art of song composition was therefore developed primarily by the professional minstrel, skillful in singing and in playing upon diverse instruments who interpreted and disseminated his master’s verses. In this respect the troubadour differed from his German contemporary the Minnesinger, who found himself a singer with no fixed instruments. The groups of minstrels were included under the old general term of *joueurs* or *joueurs de glènes* or *minstrels*, whose function was to entertain and amuse, but there were among them many subtle distinctions and ranks, such as *chantiers* and *estrumaniers*. Love was the prevailing theme in the south, while in the north war and heroic deeds inspired the bards. To the former was due the rapid development of bowed instruments, which by reason of their singing quality were more suitable for accompanying passionate love songs, while instruments of which the strings were plucked accorded better with the declamatory and dramatic style of the north.

The first assertive move towards independence was made by the wandering musicians in the 13th century, when some of these, tired of a roving life, settled down in cities, forming gilds or brotherhoods for the protection of their mutual interests and privileges. In time they came to be recognized by the burgomasters and municipalities, by whom they were engaged to provide music at all civic and private festivities, wandering musicians being prohibited from playing within the precincts of the cities. The oldest of these gilds was the Brotherhood of Nicolai founded in Venice in 1288. In 1354 and 1355 the first brotherhood Peter von Eberstorff, from Adi 1354 to 1376 known as *Vogt der Musikanten*, who obtained for the members an imperial charter. This example was gradually followed in other parts of Germany and elsewhere in Europe.

In England, John of Gaunt was in 1381 chosen King of the Minstrels. In France there was the Confrérie St. Julien des Menestriers, incorporated in 1321. Exalted patrons of instrumental music multiplied in the 15th century, to instance only the dukes of Burgundy, the emperors of the House of Austria, the dukes of Lorraine, of Este, Ferrara and Tuscany, the electors of Saxony and the kings of France with their renowned institutions *La Chappelle-Musique du Roi* (c. 1440), *La Musique de la Chambre*, *La Musique de la Grande Ecurie du Roi*. At the time of the revival of the drama with music, afterwards modified and known as opera, at the end of the 16th century, there was as yet no orchestra in the sense of the word, but merely an abundance of instruments used in concert for special effects, without balance or grouping; small positive organs, regals, harpsichords, lutes, theorboes, archlutes and citharrone (bag and contrabass lutes), guitars, viols, lyra *da braccio* and *da gamba*, psalteries, citerns, harps, flutes, recorders, cornets, trumpets and trombones, drums and cymbals.

Monteverde was the first to see that a preponderance of strings is necessary to ensure a proper balance of tone. With the perfected models of the Cremona violins at his disposal, a quartet of strings was established, and all other strung instruments not played with the bow were ejected from the orchestra with the exception of the harp. Under the influence of Monteverde and his successors, Cavalli and Cesti, the orchestra was for itself a separate existence with music and laws of its own. As instruments were improved, new ones introduced, and old ones abandoned, instrumentation became a new and favourite study in Italy and in Germany. Musicians began to find out the capabilities of various families of instruments and their individual value.

The proper understanding of the compass and capabilities of wind instruments, and more especially of the brass wind, was of later date (18th century). At first the scores contained but few indications for instruments other than strings; the others played as much as they could according to the compass of their instruments at the direction of the leader. The possibility of using instruments for solos, by encouraging virtuosi to acquire great skill, raised the standard of excellence of the whole orchestra.

At first the orchestra was an aristocratic luxury, performing privately at the courts of the princes and nobles of Italy; but in the 17th century performances were given in theatres, and Germany eagerly followed. Dresden, Munich and Hamburg successively built opera houses, while in England opera flourished under Purcell, and in France under Lully, who with the collaboration of Molière also greatly improved the status of the entertainments known as *ballets*, interspersed with instrumental and vocal music.

The revival of the drama seems to have exhausted the enthusiasm of Italy for instrumental music, and the field of action was shifted to Germany, where the perfection of the orchestra was continued. Most German princes had at the beginning of the 18th century good private orchestras or Kapelle, and they always endeavoured to secure the services of the best available instrumentalists. Kaiser, Telemann, Graun, Mattheson and Handel contributed greatly to the development of German opera and of the orchestra in Hamburg during the first quarter of the century. Bach, Gluck and Mozart, the reformers of opera; Haydn, the father of the modern orchestra and the first to treat it independently as a power opposed to the solo and chorus, by scoring for the instruments in well-defined groups; Beethoven, who individualized the instruments, writing solo passages for them; Weber, who brought the horn and clarinet into prominence; Schubert, who inaugurated the conversations between members of the wood wind—all left their mark on the orchestra, leading the way up to Wagner and Strauss.

A sketch of the rise of the modern orchestra would not be complete without reference to the invention of the piston or *Clavichord* by Stölzel and Billing in 1714, and the *Silberflöte* by Silbermann in 1715. A satisfactory bass for the wind, and more especially for the brass, had long been a desideratum. The effect of this invention was felt at once: instrument-makers in all countries vied with each other in making use of the contrivance and in bringing it to perfection; and the orchestra was before long enriched by a new family of valved instruments, variously known as tubas, or euphoniums and bombardons, having a chromatic scale and a full sonorous tone of great beauty and immense volume, forming a magnificent bass.

(K.S.)
ORCHESTRION, a name applied to three different kinds of instruments. (1) A chamber organ, designed by Abt Vogler at the end of the 18th century, which in a space of 9 cub. ft. contained no less than 900 pipes, 3 manuals of 63 keys each and 39 pedals (see HARMONIUM). (2) A pianoforte with organ pipes attached, invented by Thomas Anton Kunz of Prague in 1791. This orchestroon comprises two manuals of 65 keys and 25 pedals, all of which could be used either independently or coupled. There were 21 stops, 230 strings and 360 pipes which produced 105 different combinations. The bellows were worked either by hand or by machinery. (3) A mechanical instrument, automatically played by means of revolving cylinders, invented in 1857 by F. T. Kaufmann of Dresden. It comprises a complete wind orchestra, with the addition of kettle-drums, side-drums, cymbals and triangle. (K. S.)

ORCHIA, or Uchcha (also called Tehri or Tikamgarh), a native state of Central India, in the Bundelkhand agency. Orchha is the oldest and highest in rank of all the Bundel principalities, and was the only one not held in subjection by the peshwa. Area, 2080 sq. m.; pop. (1901) 321,634; estimated revenue, £47,000; no tribute. The maharaja, Sir Pratap Singh, G.S.C.I. (born in 1854, succeeded in 1874), took a great personal interest in the development of his state, and himself designed most of the engineering and irrigation works that have been executed here within recent years. He bears the hereditary title of "First of the Princes of Bundelkhand." The state exports grain, ghi, and cotton cloth, but trade suffers from imperfect communications. The town of Orchha, the capital, is on the river Betwa, not far from Jhansi. It possesses an imposing fort, dating mainly from the early 17th century. This contains a number of palaces and other buildings connected one with another. The most noteworthy are the Rajmandir, a massive square structure of which the exterior is almost absolutely plain; and the Jahangir Mahal, of the same form but far more ornate, a singularly beautiful specimen of Hindu domestic architecture. Elsewhere among the town are fine temples and tombs, among which may be noticed the Chaturbhuj temple on its vast platform of stone. The town of Tehri or Tikamgarh, where the chief now resides, is about 40 m. S. of Orchha; pop. (1901) 14,050. It contains the fort of Tikamgarh, by which name the town is generally called, to distinguish it from Tehri in the Himalayas.

ORCHIDS. The word Orchis is used in a special sense to denote a particular genus of the Orchid family (Orchidaceae); very frequently, also, it is employed in a more general way to indicate any member of that large and very interesting group. It will be convenient here to use the word Orchis as applying to that particular genus which gives its name to the order or family, and to employ the term "orchid" in the less precise sense.

The flowers of all orchids, though extremely diverse within certain limits, and although superficially very different from those of other monocotyledons, are all formed upon one common plan, which is only a modification of that observable in such flowers as those of the narcissus or snowdrop (Galanthus). The configuration of those flowers consists essentially in the presence of a six-parted perianth, the three outer segments of which correspond to a calyx, the three inner ones to a corolla. The sepals are borne apparently from the top of the ovary—the real explanation, however, being that the end of the flower-stalk or "thalamus," as it grows, becomes tube enclosing and indeed closely adhering to the ovary, so that the latter organ appears to be beneath the perianth instead of above it as in a lily, an appearance which has given origin to the term "inferior ovary." Within the perianth, and springing from its sides, or apparently from the top of the ovary, are six stamens whose anthers contain pulmonary pollen-grains. These stamens encircle a style which is the upward prolongation of the ovary, and which shows at its free end traces of the three originally separate but now blended carpels of which the ovary consists. An orchid flower has an inferior ovary like that just described, but with the ovule on the walls of the cavity (not in its axis or centre), a six-parted perianth, a stamen or stamens and stigmas. The main distinguishing features consist in the fact that one of the inner pieces of the perianth becomes in course of its growth much larger than the rest, and usually different in colour, texture and form. So different is it that it receives a distinct name, that of the "lip" or "labellum." In place of the six stamens we commonly find but one (two in Cypripedium), and that one is raised together with the stigmatic surfaces on an elongation of the floral axis known as the "column." Moreover, the pollen, instead of consisting of separate cells or grains, consists of cells aggregated into "pollen-masses," the number varying in different genera, but very generally two, four, or eight, and in many of the genera provided at the base with a strap-shaped stalk or "caudicle," ending in a flatish gland or "viscid disk" like a boy's sucker. In Cypripedium all three stigmas are functional, but in the great majority of orchids only the lateral pair form receptive surfaces (st, fig. 3), the third being sterile and forming the rostellum which plays an important part in the process of pollination, often forming a peculiar pouch-like process (fig. 4, r) in which the viscid disk of the pollen-masses is concealed till released in the manner presently to be mentioned. It would appear, then, that the orchid flower differs from the more general monocotyledous type in the irregularity of the perianth, in the suppression of five out of six stamens, and in the union of the one stamen and the stigmas. In addition to these modifications, which are common to nearly all orchids, there are others generally but not so universally met with; among them is the displacement of the flower arising from the twisting of the inferior ovary, in consequence of which the flower is so completely turned round that the "lip," which originates in that part of the flower, conventionally called the posterior or superior part, or that

---

Fig. 1. A. Floral diagram of typical orchid flower: l, labellum; t, anther; r, rudiments of barren stamens (staminodes). B. Diagram of the symmetrical trifid flower of Fritillaria (Fritillaria).
nearest to the supporting stem, becomes in course of growth turned to the anterior or lower part of the flower nearest to the bract, from whose axil it arises. Other common modifications arise from the union of certain parts of the perianth to each other, and from the varied and often very remarkable outgrowths from the lip. These modifications are associated with the structure and habits of insects and their visits to the flowers.

Cross fertilization, or the impregnation of any given flower by pollen from another flower of the same species on the same or on another plant, has been proved to be of great advantage to the plant by securing a more numerous or a more robust offspring, or one better able to adapt itself to the varying conditions under which it has to live. This cross fertilization is often effected by the agency of insects. They are attracted to the flower by its colour or its perfume; they seek, collect or feed on its honey, and while so doing they remove pollen from the anther and convey it to another flower, there to germinate on the stigma when its tubes travel down the style to the ovary where their contents ultimately fuse with the "oospore" or immature egg, which becomes in consequence fertilized, and forms a seed which afterwards develops into a new plant (see article Angiosperms).

To facilitate the operations of such insects, by compelling them to move in certain lines so as to secure the due removal of the pollen and its subsequent deposit on the right place, the form of the flower and the conformation of its several parts are modified in ways as varied as they are wonderful. Other insects visit the flower with more questionable result. For them the pollen is an attraction as food, or some other part of the flower offers an inducement to them for a like object. Such visitors are prejudicial to the flower, and so we meet with arrangements which are calculated to repel the intruders, or at least to force them to enter the flower in such a way as not to effect mischief.

See Darwin's *Fertilization of Orchids* and similar works.

In the common orchids of British meadows, *Orchis Morio, mascula* (Shakespeare's long purples), &c., the general structure of the flower is as we have described it (figs. 2, 3). In addition there is in this particular genus, as indeed in many others, a long tubular spur or horn projecting downwards from the back of the lip, whose office it is to secrete and store a honeyed juice; the forepart of the lip forms an expanded plate, usually larger and more brightly coloured than the other parts of the flower, and with hairs or ridges and spots of various kinds according to the species. The remaining parts of the perianth are very much smaller, and commonly are so arranged as to form a hood overarching the "column." This column stands up from the base of the flower, almost at right angles to the lip, and it bears at the top an anther, in the two hollow lobes of which are concealed the two pollen-masses, each with its caudicle terminating below in a roundish gland, concealed at first in the pouch-like rostellum at the front of the column. Below the anther the surface of the column in front is hollowed out into a greenish depression covered with viscid fluid—this is the united stigmas. The other parts of the flower need not detain us. Such being in general terms the mechanism of the flower of a common orchis, let us now see how it acts. A bee, we will assume, attracted by the colour and perfume of the flower, alights on that part of it which is the first to attract its attention—the lip. There, guided by the hairs or ridges before-mentioned, it is led to the orifice of the spur with its store of honeyed juice. The position of this orifice, as we have seen, is at the base of the lip and of the column, so that the insect, if of sufficient size, while bending its head to insert the proboscis into the spur, almost of necessity displaces the pollen-masses. Liberated from the anthers, these adhere to the head or back of the insect by means of the sticky gland at the bottom of the caudicle (fig. 4). Having attained its object the insect withdraws, taking the pollen-masses, and visits another flower. And now occurs another device or adaptation no less marvellous than those of which mention has been made. The two anther-cases in an orchis are erect and nearly parallel one to the other; the pollen-masses within them are of course in like case, as may be thus represented II, but immediately the pollen-masses are removed movements take place at the base of the caudicle so as to effect the bending of this stalk and the placing the pollen-mass in a more or less horizontal position, thus =, or, as in the case of *O. pyramidalis*, the two pollen-masses originally placed parallel II diverge from the base like the letter V. The movements of the pollen-masses may readily be seen with the naked eye by thrusting the point of a needle into the base of the anther, when the disks adhere to the needle as they would do to the antenna of an insect, and may be withdrawn. Sometimes the lip is mobile and even sensitive to impressions, as are also certain processes of the column. In such cases the contact of an insect or other body with those processes is sufficient to liberate the pollen often with elastic force, even when the anther itself is not touched. In other orchids movements take place in different ways and in other directions. The object of these movements will be appreciated when it is remembered that, if the pollen-masses retained the original direction they had in the anther in which they were formed, they would, when transported by the insect to another flower, merely come in contact with the anther of that flower, where of course they would be of no use; but, owing to the divergences and flexions above alluded to, the pollen-masses come to be so placed that, when transplanted to another flower of the same species, they come in contact with the stigma and so effect the fertilization of that flower. These illustrations are comparatively simple; it would have been easy to select others of a more complicated nature, but all evidently connected with the visits of insects and the cross fertilization of the flower. In some cases, as in *Calasetus*, male flowers are produced so different from the female that before the different flowers had been found on the same pike, and before the facts of the case were fully known, they were taken to be representatives of distinct genera.

The fruit is a capsule splitting generally by three longitudinal slits forming valves which remain united above and below. The seeds are minute and innumerable; they contain a small rudimentary embryo surrounded by a thin loose membranous coat, and are scattered by means of hygroscopic hairs on the inside of the valves which by their movements jerk out the seeds. The floral structure is so curious that perhaps less attention has been paid to the vegetative organs than the peculiarities of their organisation demand. We can only allude to some of these points. The orchids of British fields are all of terrestrial habit, and their roots are mostly tuberous (fig. 6), the tubers being partly optical partly bulbous in their character. There is often a marked alternation in the production of vegetative and flowering shoots respectively; and, sometimes, from various circumstances, the flowering shoots are not produced for several years in a succession. This fact will account for the profusion with which some orchids, like the common bee orchis for instance, are found in some seasons and their scarcity in others. Tropical orchids are mostly epiphytal—that is, they grow upon trees without deriving nourishment from them. They are frequently provided with "pseudo-bulbs," large solid swellings of the stem, in the tissues of which water and nutritive materials are stored. They derive this moisture from the air by means of aerial roots, developed from the stem and bearing an outer spongy structure, or velamen, consisting of empty cells kept open by spiral thickenings in the wall; this sponge-like tissue absorbs dew and rain and condenses the moisture of the air and passes it on to the internal tissues.
The number of species of orchids is greater than that of any other monocotyledonous order—not even excepting grasses—amounting to 60,000, contained in 400 genera. This large number is partly accounted for by the diligent search in all countries that has been made, six for these plants for purposes of cultivation—they being held at present in the greatest esteem by plant-lovers, and prices being paid for new or rare varieties which recall the days of the tulipomania.

The economic uses of orchids are not remarkable. When we have mentioned vanilla (g.v.), which consists of the fleshy pods of an orchid, we have mentioned about the only economic product that now comes into market. Salep (g.v.), still used in the Levant, consists of the dried tubers of a terrestrial orchid, and contains a relatively large amount of nutritious matter.

The cultivation of orchids is treated under Horticulture.

The order is divided into two main groups based on the number of the stamens and the shape, genera of Orchis consist of three stamens and three functional stigmas. It contains two small genera of tropical Asia and Africa with almost regular flowers, and the large genus Cypripedium containing about 80 species in the north-temperate zone and tropical Asia and America. In Cypripedium the ovary changes on each side of the column instead of one only at the top, as in the group Monandreae, to which belong the remaining genera in which also only two stigmas are fertile. What may be considered the normal number of stamens is, as has been already stated, three; in most genera the only stamens developed to maturity is the posterior one of the three, and the other two, as well as all three inner ones, are entirely absent, or present only in the form of rudiments. In Cypripedium two of the outer stamens are wanting; the third—the one, that is, which corresponds to the single fertile stamen in the Monandreae—forms a large sterile structure or staminode; the two lateral ones of the indeterminate stamens are present, the third being undeveloped. This arrange-ment may be understood by reference to the following diagram, representing the relative position of the stamens in orchids generally, and in Cypripedium. The letter L indicates the position of the labellum; the large figures indicate the developed stamens; the italic figures show the position of the suppressed stamens.

Arrangement of stamens in Orchis.

Arrangement of stamens in Cypripedium.

The Monandreae have been subdivided into twenty-eight tribes, based on the characters of the flowers and seeds, the nature of the inflorescence, whether terminal or lateral, the vernation of the leaf and the presence or absence of a joint between blade and sheath, and the nature of the stem. The most important are the following:

Neottiumae, with 45 genera, of terrestrial orchids, mainly north temperate, including the British genera Orchis, Aceras, Ophrys, Herminium, Gymnadenia and Habenaria. Also some genera mainly represented in South and tropical Africa, such as Satyrium, Dina and others.

Neottiumae, including 90 genera, also terrestrial, contains thirteen more or less widely distributed tropical or subtropical subtribes, of which extend into temperate zones; one, Cephalantherae, which includes our British genera Cephalanthera and Epipactis, is chiefly north temperate. The British genera Spiranthes, Listera and Neottia are also included in this tribe, as also Vanilla, the elongated stem of which by means of tendril-like aerial roots—the long yellow pod is a vanilla used for flavouring.

Collegynae, 7 genera, mostly epiphytes, and inhabitants of tropical Asia. A single internode of each shoot is swollen to form a pseudobulb.

Neottioideae, 9 genera, terrestrial, two, Malaxis and Corollorhiza, are British. Liparis is a large genus widely distributed in the tropics.

Pleurothallidinae, characterized by a thin stem bearing one leaf which separates at a distinct joint, the flowers are usually much larger than other genera. Includes genus Phaius. One of the tropical America, one of which, Pleurothallis, contains about 400 species. Masdevallia is common in cultivation and has often brilliant scarlet, crimson or orange flowers. It is native of the warmer parts of America, including three of those best known in cultivation, Epipactis, Bulbophyllum and Laelia. The jointed leaves are fleshy or leathery; the flowers are generally large with a well-developed lip. Odontoglossum, includes 44 genera chiefly tropical American, one—Phaius and Calanthe—spreading northwards into China and Japan.

Cystostylinae, includes 9 genera tropical, but extending into north temperate Asia and South Africa; Eulophia and Lisochilus are important African genera.

Catasetinae, with three tropical American genera, two of which, Catasetum and Cynorchis, have di- or tri-morph flowers. They are cultivated for their strange-looking flowers, and one, Catasetum Guatemala, with 8 genera in the tropics of the Old World. The leaves are generally long and narrow. Cymbidium is well known in cultivation.

Oncidinae, with 44 genera in the warmer parts of America. Odontoglossum and Oncidium include some of the best-known cultivated orchids.

Sarcochilinae, with 42 genera in the tropics, Vanda (Asia) and Angraecum (Africa and Madagascar) are known in cultivation. The flower of Angraecum sesquipedale has a spur 18 in. in length.

The order is well represented in Britain by 18 genera, which include several species of Orchis—Gymnadenia (fragrant orchis), Habenaria (butterfly and frog orchis), Acaena (man orchis), Herminium (musk orchis), Ophrys (bee, spider and fly orchis), Epipactis (Cephalanthera), Neottia (bird’s nest orchis), one of the few saprophytic genera, which have no green leaves, but derive their nourishment from decaying organic matter in the soil, Listeria (Tway blade), Spiranthes (lady’s tresses), Malaxis (fragrant orchis), Liparis (fern-orchis), Corallorhiza (coral root), also a saprophyte, and Cypripedium (lady’s slipper), represented by a single species now very rare in limestone districts in the north of England.

**ORCHOMENUS** (local form on coins and inscriptions, *Orchomenos*), the name borne by two cities of ancient Greece.

1. A Boeotian city, situated in an angle between the Cephissus and its tributary the Melas, on a long narrow hill which projects south from Mount Acontium. Its position is exceedingly strong, being defended on every side by precipice or marsh or river, and it was admirably situated to be the stronghold of an early kingdom. The acropolis is at the north end of the hill, on a peak which is overhung by Acontium, but at a distance sufficient to be safe from an enemy with the weapons of early warfare posted on the mountain. At the foot of the acropolis are the springs of the Melas.

In prehistoric times Orchomenos, as is proved alike by archaeological finds and by an extensive cycle of legends, was one of the principal places of Greece. It was a political, military and a maritime power. On the mainland it controlled the greater part of Boeotia and drew its riches from the fertile lowlands of Lake Copais, upon the drainage of which the early kings of Orchomenos bestowed great care. Its maritime connexions have not been as yet determined, but it is clear that its original inhabitants, the Minyae, were a seafaring nation, and in historical times Orchomenus remained a member of the Calaurian League of naval states. At the end of the second millennium the Minyae were more or less supplanted by the incoming stock of Boeotians. Henceforth Orchomenos no longer figures as a great commercial state, and its political supremacy in Boeotia passed now, if not previously, to the people of Thebes. Nevertheless, owing perhaps to its strong military position, it long continued to exercise some sort of overlordship over other towns of northern Boeotia, and maintained an independent attitude within the Boeotian League. In 447 it served as the headquarters of the oligarchic exiles who freed Boeotia from Athenian control. In the 6th century Orchomenos was acquired through an unknown agency, which may have been nothing more than a recrudescence of old-time rivalry, but seems chiefly inspired by aversion to the newly established democracy at Thebes. In the Corinthian War the city supported Lyons and Agesilaus in their attacks upon Thebes, and when war was renewed between the Thebans and Spartans in 379 Orchomenos again sided with the latter. After the battle of Leuctra it was left at the mercy of the Thebans, who first, on Epaminondas’ advice, re-admitted it into the Boeotian League, but in 368 destroyed the town and exterminated or enslaved its people. By 353 Orchomenos had been rebuilt, probably by the Phocians, who used it as a bulwark against Thebes. After the subjection of the Phocians in 346 it was again razed by the Thebans, but was restored by Philip of Macedon as a check upon the latter (338). Orchomenos springs into prominence once again in 85 B.C., when it provided the battle-field on which
the Roman general Sulla destroyed an army of Mithradates VI. of Pontus. Apart from this event its later history is obscure, and its decadence is further attested by the neglectful drainage of the plain and the occurrence of salt marshes at Lake Copais. Since medieval times the site has been occupied by a village named Skripou. Since 1867 drainage operations have been resumed, and the land thus reclaimed has been divided into small holdings. The most remarkable relic of the early power of Orchomenus is the so-called “treasury” (of “Minyas”) which resembles the buildings of similar style at Mycenae (see MYCENAE), and is almost exactly the same size as the treasury of Atreus. The admiration which Pausanias expresses for it is justified by the beautiful ornamentation, especially of the roof, which has been brought to light by Schliemann's excavations in the inner chamber opening out of the circular vaulted tomb. The monument, undoubtedly the tomb of some ancient ruler, or of a dynasty, lies outside the city walls. Other remains of early date have been found upon this site.

The worship of the Charites (see GRACES) was the great cultus of Orchomenus, and the site of the temple is now occupied by a chapel, the Κολυμπα της Αλαραγιας. The Charites were worshipped under the form of rude stones, which had fallen from heaven during the reign of Eteocles; and it was not till the time of Pausanias that statues of the goddesses were placed in the temple. This was the temple dedicated to Dionysus, in whose festival, the ‘Αφγουροι are apparent the traces of human sacrifice in early times (see AGRIOLA).

2. An Arcadian city, situated in a district of the same name, north of Mantinea and west of Stymphalus. The district was mountainous, but embraced two valleys—the northern containing a lake which is drained, like all Arcadian lakes, by a katovaltron; the southern lying under the city, separated from Mantinea by a mountain ridge called Anchisia. The old city occupied a strong and lofty situation; in the time of Strabo it was a ruin, but Pausanias mentions that a new town was built below the old. A primitive wooden image of Artemis Cede ratis stood in a large cedar tree outside the city. Orcho menus is mentioned in the Homeric catalogue with the epithet πολυμυθος.

In early history Orchomenus figures as a town of some importance, for its kings until the late 7th century B.C. held some sort of sovereignty over all Arcadia. In the 5th century it was overshadowed by its southern neighbour Mantinea, with whom it is henceforth generally found to be at variance. In 418 B.C. Orchomenus fell for a time into the hands of the Mantinians; in 370 it held aloof from the new Arcadian League which the Mantinians were organizing. About this time it further declined in importance through the loss of some possessions on the east Arcadian watershed to the new Arcadian capital Megalopolis. In the 3rd century Orchomenus belonged in turn to the Aetolian League, to the Lacedaemonians, and, since 222, to the Achaean League. Though a fairly extensive settlement still existed on the site in the 2nd century A.D., its history under the Roman rule is quite obscure.

See Pausanias, viii. chs. 5, 11-13, 27; B. V. Head, Historia nemorum (Oxford, 1887), pp. 577-578.

**ORCIN** a dioxytoluene, \( \text{C}_8\text{H}_8\text{(CH}_3\text{)}\text{(OH)}_2 \) (1 : 3 : 5), found in many lichens, e.g. **Rocella tinctoria**, **Lecanora**, and formed by fused extract of aloes with potash. It may be synthesized from toluene; more interesting is its production when acetone dicarboxylic ester is condensed with the aid of sodium. It crystallizes in colourless prisms with one molecule of water, which reddens on exposure. Ferric chloride gives a bluish-violet colouration with the aqueous solution. Unlike resorcin it does not give a fluorescein with phthalic anhydride. Oxidation of the ammoniacal solution gives orcein, \( \text{C}_9\text{H}_8\text{N}_2\text{O}_4\), the chief constituent of the natural dye archil (q.v.). Homo-pyrocathechin is an isomer (\( \text{CH}_3\text{OH} : \text{OH} = 1 : 3 : 4 \)), found as its methyl ether (creosol) in beech-wood tar.

**ORDEAL** (O.Eng. ordele, ordele, judgment), a term corresponding to modern Ger. **Urteil**, but bearing the special sense of the medieval Lat. **Dei judicium**, a miraculous decision as to the truth of an accusation or claim. The word is adopted in the late Lat. **ordalium, Fr. ordale**. The ordeal had existed for many ages before it was thus named in Europe. In principle, and often in the very forms used, it belongs to ancient culture, thence flourishing up to the medieval European and modern Asiatic levels, but dying out before modern civilization. Some ordeals, which possibly represent early stages of the practice, are simply magical, being processes of divination turned to legal purpose. Thus in Burma suits are still determined by plaintiff and defendant being each furnished with a candle, equal in size and both lighted at once—he whose candle outlasts the other being adjudged, amid the acclamations of his friends, to have won his case (Shway Yoe, The Burman, ii. 254).

Even quainter is a Dyak ordeal in Borneo, where the two parties are represented by two shell-fish on a plate, which are irritated by pouring on some lime-juice, and the one first moving settles the guilt or innocence (as has been before arranged) of its owner (St John, Forests of the Far East, i. 89). The administration of ordeals has been much in the hands of priests, and they are more often than not worked on a theological basis, the intent being that of a fairy being involved and assumed to take place even when the process is in its nature one of symbolic magic. For instance, an ancient divining instrument consisted of a shield suspended by a thread or by a pair of shears with the points stuck into its rim, and considered to move at the mention of the name to be discovered, &c. Thus girls consulted the “sieve-witch” (κορωναίας) about lovers (Theocr., Idyl. iii. 31). This coccinomancy served in the same way to discover a thief, when, with prayer to the gods for direction, the names of the suspected persons were called over to it (Potter, Greek Antiquities, i. 352). When a suspended hatchet was used in the same way to turn to the guilty, the process was called axinomancy. The sieve-ordeal remained popular in the middle ages (see the description and picture in Cornelius Agrippa, De Occ. Phil.); it is mentioned in Hudibras (ii. 3):

"... th' oracle of sieve and shears
That turns as certain as the spheres."

From this ancient ordeal is evidently derived the modern Christian form of the key and Bible, where a Psalter or Bible is suspended by a key tied in at Psalm 1. 18: "When thou sawest a thief, then thou consorted with him"; the bow of the key being balanced on the head. The names of those suspected being called over, he or she at whose name the bow turns or falls is the culprit (see Brand, Popular Antiquities, ed. Bohn, i. 351).

One of the most remarkable groups of divinations passing into ordeals are those which appeal to the corpse itself for discovery of its murderer. The idea is rooted in that primitive state of mind which has not yet realized the full effect of death, but regards the body as still able to hear and act. Thus the natives of Australia will ask the dead man carried on his bier of boughs, who bewitched him; if he has died by witchcraft he will make the bier move round, and if the sorcerer who killed him be present a bough will touch him (Eyre, Australia, ii. 344). That this is no isolated fancy is shown by its recurrence among the negroes of Africa, where, for instance, the corpse causes its bearers to dash against some one's house, which accuses the owner of the murder (J. L. Wilson, Western Africa, p. 231; Waltz, ii. 193). This somewhat resembles the well-known ordeal of the bier in Europe in the middle ages, which, however, seems founded on a different principle, the imagination that a sympathetic action is occurring between the corpse and the head of the murderer. Apparently the liquefaction of the blood which in certain cases takes place after death may have furnished the ground for this belief. On Teutonic ground, this ordeal appears in the Nibelungenlied, where the murdered Siegfried is laid on his bier, and Hagen is called on to prove his innocence by going to the
corps, but at his approach the dead chief's wounds bleed afresh. The typical instance in English history is the passage of Matthew Paris, that after Henry II. 's death at Chinon his son Richard came to view the body. "Quo superveniret, confestim erupit sanguis ex naribus regis mortui; ac si indignaretur spiritus in adventu ejus, qui ejusdem mortis causa esse credebatur, ut videreetur sanguis clamare ad Deum." In Shakespeare (Rich. III., act 1, sc. 2): "O gentlemen, see, see! dead Henry's wounds Open their congeald mouths, and bleed afresh!

At Hertford assizes (1628) the deposition was taken as to certain suspected murderers being required to touch the corpse, when the murdered woman thrust out the ring finger three times and it dropped blood on the grass (Brand, iii. 231); and there was a case in the Scottish High Court of Justiciary as late as 1668 (T. F. Thistleton Dyer, Folkslore of Shakespeare, p. 487). Durham peasants, apparently remembering the old belief, still expect those who come to look at a corpse to touch it, in token that they bear no ill-will to the departed (W. Henderson, Folklore of Northern Counties, p. 57).

Certain ordeals are closely related to oaths, so that the two shade into one another. Let the curse which is to fail on the oath-bearer take effect, but he has sworn to administer the medicine—in fact, an ordeal. Thus the drinking of water on which a curse or magical penalty has been laid is a mere oath so long as the time of fulfilment is unfixèd (see OATH). But it becomes an ordeal when, as in Brahmanic India, the accused drinks three handfuls of water in which a sacred image has been dipped; if he is innocent nothing happens, but if he is guilty sickness or misfortune will fall on him within one to three weeks (for accounts of these and other Hindu ordeals see Ali Ibrahim Khan in Asiatic Researches, i. 380, and Stenzler's summary in Z. D. M. G., vol. ix.). The earliest account of such an ordeal is in Numbers v., which describes the mode of administering to a woman charged with unfaithfulness the bitter water mixed with the dust of the tabernacle floor, with the curse laid on it to cause her belly to swell and her thigh to fall if guilty. Ewald (Antiquities of Israel, 326) regards the draught as in itself harmlessness, and the operation of this curse on the guilty as due to the influence of the mind on the body. But the term "bitter" is applied to the water before it has been cursed, which suggests that it already has a degree of virtue in it. Thus in the earlier disputes an ordeal still in constant use over a great part of Africa. Thus the red water of Guinea is a decoction made by pounding in a wooden mortar and steeping in water the inner bark of one of the nkomas, producing a liquor like that of a tan-vat, astringent, narcotic, and when taken in sufficient quantity emetic. The accused, with solemn ceremony and invocation, drinks freely of it; if it nauseates him and he throws it up he is triumphantly acquitted, but if he becomes dizzy he is guilty, and the assembly fall on him, pelt him with stones and even drag him over the rocks till he is dead. Here the result of the ordeal depends partly on the patient's constitution, but more on the sorcerer who can prepare the proper dose to prove either guilt or innocence. Among the various drugs used in different parts of Africa are the mbundu root, the Calabar bean, the tangena nut (Tanghinia venenifisa, a strong poison and emetic). The sorcerers who administer this ordeal have in their hands a power of inflicting or remitting judicial murder, giving them boundless influence (details in J. L. Wilson, Western Africa, pp. 225, 308; Burton, Lake Regions of Central Africa, 1857; Bosman, "Guinea," in Pinkerton's Voyages, xvi. 398, &c.). The poison-ordeal is also known to Brahmanic law, deiction of aconite root being one of the poisons given, and the accused if not sickness being declared free (Stenzler, l.c.). Theoretically connected with the ordeal by cursed drink is that by cursed food, which is, however, distinguished among this black catalogue by being sometimes an effectual means of discovering the truth. The ordeal by bread and cheese, practised in Alexandria about the 2nd century, was practically the same as that known to English law five to ten centuries later as the corsnæd or "trial slice" of consecrated bread and cheese which was administered from the altar, with the curse that if the accused were guilty God would send the angel Gabriel to stop his throat, that he might not be able to swallow that bread and cheese. In fact, if guilty and not a hardened offender he was apt to fall, drink-muffled and choking through terror, to get it down. The remembrance of this ancient ordeal still lingers in the popular phrase. "May this bit choke me if I lie!" In India the corresponding trial by rice is prescribed in the old laws to be done by suspected persons chewing the consecrated grains of rice and spitting them out, moist and untinged with blood, on a banyan leaf; or this or the mere chewing and swallowing of a mouthful of rice-grains is often used even by the English as a means of detecting a thief. A classical mention of the ordeals by carrying hot iron in the hands and by passing through the fire is made more interesting by the guards who offer to prove their innocence in this way offering further to take oath by the gods, which shows the intimate connexion between oaths and ordeals (Soph. Ant. 264, see also Aeschyl., fr. 284).

The passing through the fire is described in the Hindu codes of Vajavalkya and others, and is an incident in Hindu poetry, where in the Rāmāyana the character of Sita thus proves her innocence to her jealous husband Rāma (Stenzler, p. 669; Pictet, Origines Indo-Européennes, part ii. p. 437). It was not less known to European law and chronicle, as where Richardis, wife of Charles the Fat, proves her innocence by going into a fire clothed in a waxed shield, and is unhurt by the fire (Grimm, Deutsche Rechtsalterthümer, p. 912). Yet more minutely prescribed in the Hindu ordeal-books is the rite of carrying the glowing hot iron seven steps, into the seven or nine circles traced on the ground, the examination of the hands to see if they show traces of burning, and the binding them up in leaves. The close historical connexion of the Hindu ordeal laws with the old European is shown by the correspondence of minute details, as where in a Scandinavian law it is prescribed that the red-hot iron shall be carried nine steps (Grimm, op. cit., p. 918). In Anglo-Saxon laws the iron to be carried was at first only one pound weight, but Athelstan's law (in Ancient Laws and Institutes of England, iv. 6) enacts that it be increased to weigh three pounds. The purpose of the ordeal is to demonstrate that the accused is innocent; in all the countries of Germany and England was the walking barefoot over glowing hot coals, generally nine. The law-codes of the early middle ages show this as an ordinary criminal procedure (see the two works last referred to), but it is perhaps best remembered in two non-historical legends. The German queen Kunigunde, "haec dicens stupendius et fientibus universis qui aerant, voveres candentes nudo vestigio calcavit et sine adustionis molestia transit." (Vista Henrici, ap. Canisium, vi. 387). Queen Emma, mother of Edward the Confessor, accused of familiarity with Alwyn bishop of Winchester, triumphantly purges herself and him by the help of St Swithin—of the two thus acquitted giving nine manors to the church of Winchester, in memory of the nine ploughshares, and the king being corrected with stripes (John Bromton, see Freeman's Norm. Conq., vol. ii. App.). To dip the hand in boiling water or oil and melted lead and take out a stone or ring is another ordeal of this class. The traveller may find some of these fiery trials still in use, or at least in recent memory, in barbaric regions of Africa or further Asia—the negro plunging his arm into the cauldron of boiling oil, the Burman doing feats with melted lead, while the Hindus still make evidence by the opposing witnesses licking a glowing hot-iron spoon (Burchhardt, Arabien, pp. 98, 233). This latter feat may be done with safety by any one, provided the iron be clean and thoroughly hot white, while if only red-hot it would touch and burn the tongue. Probably the administrators of the ordeal are aware of this, and of the possibility of dipping the hand in melted metal; and there are stories of arts of protecting the skin (see the recipe in Albertus Magnus, De Mirabilibus), though it is not known what can be really done beyond making it horny like a smith's, which would serve as a defence in stepping on
ORDER

hot coals, but not in serious trials like that of carrying a heavy red-hot iron. The fire-ordeals are still performed by mountebanks, who very likely keep up the same means of trickery which were in official use when the accused was to be acquitted. The actual practice of the fire-ordeal contrasts shamefully with its theory, that the fire rather than the innocent restrained its natural action. Thus it stands in the Hindu code of Manu (viii. 115): “He whom the flame does not burn, whom the water does not cast up, or whom no harm soon befals, is to be taken as truthful in his oath.” The water-ordeal here referred to is that well known in Europe, where the accused is thrown bound into the water, which receives him if innocent, but rejects him if guilty. The manner of carrying out this test is well explained in the directions given by Archbishop Hincmar in the 9th century: he who is let down into the water for trial is to be fastened by a rope, that he may not be in danger if the water receives him as innocent, but may be pulled out. In the later middle ages this ordeal by “swimming” or “fleeting” became the most approved means of trying a suspected witch: she was stripped naked and cross bound, the right thumb to the left toe, and the left thumb to the right toe. In this state she was cast into a pond or river, in which it was thought impossible for her to sink (Brand iii. 21). The cases of “ducking” witches which have occurred in England within the last few years are remains of the ancient ordeal.

If there is one thing that may be predicated of man in a state of nature it is that two disputants tend to fight out their quarrel. When in the warfare of Greeks and Trojans, of Jews and Philistines, of Vandals and Alamans, heroes come out from the two sides and their combat is taken to mark the powers of the opposing war-gods and decide the victory, then the principle of the ordeal by battle has been practically called in. Among striking instances of the Teutonic custom which influenced the whole of medieval Europe may be cited the custom of the Franks that the princes, if they could not quell the strife, had to fight it out between themselves, and Wipo’s account of the quarrel between the Christian Saxons and the Pagan Slavs as to which broke the peace, when both sides demanded of the emperor that it should be settled by duel, which was done by choosing a champion on each side, and the Christian fell. The Scandinavian term “holmgang” refers to the habit of fighting duels on an island. A passage from old German law shows the single combat accepted as a regular legal procedure: “If there be dispute concerning fields, vineyards, or money, that they avoid perjury let two be chosen to fight, and decide the cause by duel” (Grimm, Rechtsaltert., p. 926). In England, after the Conquest, trial by combat superseded other legal ordeals, which were abolished in the time of Henry III. Among famous instances is that of Henry de Essex, hereditary standard-bearer of England, who fled from a battle in Wales, in 1158, threw from him the royal standard, and cried out that the king was slain. Robert de Montfort afterwards, accusing him of having done this with treasonable intent, offered to prove his accusation by battle, and they fought in presence of Henry II. and his court, when Essex was defeated, but the king spared his life, and, his estate being confiscated, he became a monk in Reading Abbey. A lord often sent his man in his stead to such combats, and priests and women were ordinarily represented by champions. The wager of battle died out so quietly in England without being legally abolished that in the court of king’s bench in 1818 it was claimed by a person charged with murder, which led to its formal abolition (Ashford v. Thornton in Barnewall and Alderson 457; see details in H. C. Lea, Superstition and Force, ii.). A distinct connexion may, however, be traced between the legal duel and the illegal private duel, which has disappeared from England, but still flourishes in France and Germany (see DUEL).

ORDER (Fr. ordre, for earlier ordeone, from Lat. ordo, ordinis, rank, service, arrangement; the ultimate source is generally taken to be the root seen in Lat. oriri, rise, arise, begin; cf. “origin”), a row or series, hence grade, class or rank, succession, sequence or orderly arrangement; from these, the original meanings of ordo, have developed the numerous applications attached to the word, many, if not most, of which appear in classical and medieval Latin. In the sense of a class or body of persons or things united by some common status, rank or distinguishing characteristics, or as organized and living under some common rule or regulations, the word finds, in such expressions as “lower” or “higher” orders, to the class divisions of society; to the various grades of persons exercising spiritual functions in the Christian church (see ORDER, HOLY, below); to the bodies of persons bound by vows to a religious life (see MONASTICISM, and separate articles on the chief religious orders); to the military and monastic fraternities of the middle ages, such as the Templars, Hospitallers, &c., and to those institutions, founded by sovereigns or states, in part imitation of these fraternities, which are conveniently divided into orders of knighthood, or orders of merit (see KNIGHTHOOD). The term “order” is thus used, in an easily transferred sense, for the various insignia, badge, star, collar, worn by the members of the institution. As applied to a group of objects, an “order” in zoological, botanical and mineral classification ranks next below a “class,” and above a “family.” The use of the word in architecture is treated in a separate article below.

The word has several technical mathematical usages. In number-theory it denotes a relative rank between the elements of an aggregate so that the collection becomes an ordered aggregate (see NUMBER). The order of a plane curve is the number of points (real or imaginary) in which the curve is intersected by a straight line; it is equal to the degree (or coefficient of the highest power) of the Cartesian equation expressing the curve. The order of a non-plane curve is the number of points (real or imaginary) in which the curve intersects a plane (see CURVE). The order of a surface is the number of points in which the surface intersects a straight line. For the order of a congruence and complex see SURFACE. The order of a differential equation is the degree of its highest differential coefficient (see DIFFERENTIAL EQUATION).

Another branch of the sense-development of the word starts from the meaning of orderly, systematic or proper arrangement, which appears in the simplest form in such adverbial expressions as “in order,” “out of order” and the like. More particular instances are the use of the word for the customary procedure observed in the conduct of the business of a public meeting, or of parliamentary debates, and for the general maintenance and due observance of law and authority, “public order.”

In liturgical use “order” is a special form of divine service prescribed by authority, e.g. the “Order of Confirmation,” in the English Prayer Book.

The common use of “order” in the sense of a command, instruction or direction is a transference from that of arrangement in accordance with intention to the means for attaining it. It is a comparatively late sense-development; it does not appear in Latin, and the earliest quotations in the New English Dictionary are from the 16th century. Particular applications of the term are, in commercial usage, to a direction in writing to a banker or holder of money or goods, by the person in whom the legal right to them lies, to pay or hand over the same to a third person named or to his order. A bill or negotiable instrument made “payable to order” is one which can be negotiated by the payee by endorsement. At common law a negotiable instrument must contain words expressly authorising transfer. By the Bills of Exchange Act 1882, § 8, “a bill is payable to order which is expressed to be so payable, or which is expressed to be payable to a particular person, and does not contain words prohibiting transfer or indicating an intention that it should not be transferable.” Other applications are to a direction for the supply of goods and to a pass for free admission to a place of amusement, a building, &c.

In law an “order of the court” is a judicial direction on matters outside the record; as laid down by Esher, M.R., in Onslow v. Inland Revenue, 55, L.J.Q.B. 556, a “judgment” is a decision obtained in an action and every other decision is an “order.” For “Order in Council” see below.
ORDER

in, classic architecture the term employed (Lat. genus, Ital. ordine, Sp. orden, Ger. Ordnung) to distinguish the varieties of column and entablature which were employed by the Greeks and Romans in their temples and public buildings. The first attempt to classify the architectural orders was made by Vitruvius, who, to those found in Greek buildings, viz. the Doric, Ionic and Corinthian, added a fourth, the Tuscan. On the revival of classic art in Italy, the revivalists translated Vitruvius's work De Architectura, and added a fifth example, the Composite, so that nominally there are five orders. The Tuscan, however, is only an undeveloped and crude modification of the Doric order, and the Composite is the same as the Corinthian with the exception of the capital, in which the volutes of the Ionic order were placed above the acanthus leaves of the Corinthian.

An order in architecture consists of several parts, constructive in their origin, but, as employed afterwards, partly constructive and partly decorative; its principal features are the column, consisting of base (except in the Greek Doric order), shaft and capital, and the entablature, subdivided into the architrave (the supporting member), the frieze (the decorative member) and the cornice (the crowning and protecting member). Two only of the orders were independently evolved, viz. the Doric in Greece and the Composite in Rome; the Greek Doric order, the Greeks borrowed with slight variations the entablature for their Ionic order, and the Romans employed this modified entablature for their Composite order. Owing to a certain resemblance in form, it was at one time thought that the Greeks owed the origin of the Doric order to Egypt, but the Egyptian column has no echinus under its abacus, which in the earliest Doric examples is an extremely important element in its design, owing to its great size and projection; moreover, the Doric column ceased to be employed in Egypt after the XIXth Dynasty, some seven or eight centuries before the first Greek colony was established there. Dr Arthur Evans's discoveries in the palace of Cnosus in Crete have shown that the earliest type of the Doric column (c. 1500 B.C.) is that painted in a fresco which represents the façades of three temples or shrines, the truth of this representation being borne out by actual remains in the palace; the columns were in timber, tapering from the top downwards, and were crowned by a projecting abacus supported by a large tortoise moulding, probably moulded in stucco. The next examples of the Doric order are those in stone, which flank the entrance doorway of the temple of Minerva at Agrigentum (c. 1200 B.C.), the capitals of which are now set up in the British Museum; and here both capital and shaft are richly decorated with the chevron pattern, probably derived from the metal plates which in Homeric times sheathed the wood columns. The columns of the Mycenae tombs are semi-detached only, and of very slender proportions, averaging 10 to 11 diameters in height; as isolated columns, therefore, they would have been incapable of carrying any weight, so that in the next examples known, those of the temple at Corinth, where the columns had to carry an entablature in stone supporting a stone ceiling over the peristyle, the relation of diameter to height is nearly one to four, so different were the Greek architects as to the bearing power of the stone. In the temple of Apollo at Syracuse, also a very archaic example, the projection of the capital was so great that the abaci nearly touched one another, and the columns are less than one diameter apart. The subsequent development which took place was in the lightening of the column and the introduction of many refinements, so that in the most perfected example known, the Parthenon capital of the Erechtheum at Athens (c. 460 B.C.), the columns are nearly 55 diameters high. In a somewhat later example, the temple of the Nemean Zeus (Argos) the columns are 65 diameters high. A similar lightening of the structure took place in the entablature, which in the earliest temple in Sicily is about half the height of the columns, in the Parthenon less than a third, and in the Temple of the Nemean Zeus a little over a fourth.

The origin of the Ionic order is not so clear, and it cannot be traced beyond the remains of the archaic temple of Diana at Ephesus (c. 560 B.C.), now in the British Museum, in which the capitals and the lower drum of the shaft enriched with sculpture in their design and execution suggest many centuries of development. Here again attempts have been made to trace the source to Egypt, but the volute capital of the archaic temple of Diana at Ephesus and the decorative lotus bud of Egypt are entirely different in their form and object. The latter is purely decorative and vertical in its tendency, the former is a feature intended to carry a superincumbent weight, and is extended horizontally so as to perform the function of a bracket-capital, viz. to lessen the bearing of the architrave or beam which it carries. A similar constructive expedient is found in Persian work at Persepolis, which, however, dates about forty years later than the Ephesian work. The volutes of the capitals of the Lycian tombs are none of them older than the 4th century, being copies of Greek stone examples. As with the Doric order, the columns became more slender than at first, those of the archaic temple being probably between 6 and 7 diameters high, of the temple on the Ilius (c. 450 B.C.) 8½, and of the temple of Athena Polias at Priene (c. 345 B.C.) over 10 diameters high.

The employment of the two orders in Athens simultaneously, and sometimes in the same building, led to a reciprocal influence on one on the other: in the Doric order to an increased refinement in the contour of its mouldings, in the Ionic order to greater weight, as it was now borrowed from the Egyptians. The frequent members of which were reduced in number and simplified, the dentil course (which in Ionion was a very important feature) being dispensed with in the temple on the Ilius and in that of Nike Apteros, and employed only in the caryatide portico of the Erechtheum. The capital of the Corinthian order, its only original feature, may have been derived from the Egyptian bell-capital, which was constantly employed there, even in Roman times; its decoration was, however, purely Greek, and would seem to have been based on the application to the bell of foliage and ornament derived from metallic forms. The inventor of the capital is said to have been Callimachus of Corinth, who was a craftsman in metal and designed the bronze lamp and its cover for the Erechtheum in Corinthian bronze, which may account for the origin and title of the capital. The earliest example of the Corinthian capital is that found at Bassae by Cockerell, dating from about 430 B.C., and the more perfected type is that of the Tholos of Epidaurus (400 B.C.).

Whilst the entablatures of the Doric and Ionic orders suggest their origin from timber construction, that of the Corinthian is probably a simple expedient in the case of the Romans affords the only instance of their improvement of a Greek order (so far as the independent treatment of it was concerned) by the further enrichment of the bed mould of the corincne, where the introduction of the modillion gave an increased support to the corona and was a finer crowning feature.

The Greek Doric order was not understood by the Romans, and was, with one or two exceptions, utilized by them only as a decorative feature in their theatres and amphitheatres, where in the form of semi-detached columns they formed divisions between the arches; the same course was taken with the Ionic order, which, however, would seem to have been employed largely in porticoes. On the other hand, the Corinthian order, in consequence of its rich decoration, appealed more to the Roman taste; moreover, all its faces were the same, and it could be employed in rectangular or in circular buildings without any difficulty. The earliest examples are found in the temple of Castor and Pollux at Cora, near Rome, which is Greek in the style of its carving, and is the abacus of the Parthenon. The subsequent development by the Romans is fully described. The next developments of the orders are those which followed the revival of classic architecture in the 16th century, and these were largely influenced by the discovery in 1456 of the manuscript of Vitruvius, an architect who flourished in the latter half of the 1st century B.C. In his work De Architectura he refers constantly to drawings which he had prepared to illustrate his descriptions; these, however, have never been found, so that the translators of his work put their own interpretation on his text and published woodcuts representing

ORDER

ORDER
the Roman orders as defined by him. They did not, however, confine themselves to the actual remains, which in their day were in much better preservation than at present, but attempted to complete the orders by the addition of pedestals to the columns, which were not employed by the Greeks, and only under special conditions by the Romans; as, however, they are included in the two chief authorities on the subject, Palladio and Vignola, the text-book of the former being the standard in England, and that of the latter in France, the rules and proportions set forth in them for pedestals, as also for the employment of the superposing of the orders with arches between, will follow the analysis of the Greek and Roman orders.

The Greek Doric Order.—The Doric was the favourite order of the Greeks, and the one in which they introduced all their principal refinements; these were of so subtle a nature that until the site was cleared in 1837 their existence was not known, and the earlier explorers, though recognizing the extreme beauty of the proportions and some of the refinements, were unable to grasp the extent to which they were carried, and it was reserved for Penrose in 1846 to verify by micrometrical studies the theories put forward by Pennethorne and other authors. The whole structure of the Doric temple (which consisted of the column, architrave, and the entablature, subdivided into architrave, frieze and cornice) rested on a plan of three steps, of which the upper step was the stylobate or column base (fig. 1). The tread and rise of the steps varied in accordance with the diameter of the column; in temples of great dimensions, therefore, supplementary steps were provided for access to the stylobate, or, as found in many temples, slight inclined planes. Resting on the stylobate was the shaft of the column, which was either monolithic or composed of frusta or drums. The shaft tapered as it rose, the diminution of the upper diameter being more pronounced in early examples, as in one of the temples at Selinus and in the great temple at Paestum. In the Parthenon at Athens the lower diameter is 6 ft. 3 in. and the upper 4 ft. 9 in., which gives a diminution slightly over one-quarter of the lower diameter. The shaft was always fluted, with two or three exceptions, where the temples were not completed, and there were usually twenty flutes. In two temples at Syracuse, the most ancient temple at Selinus, the temple at Assos, and the temple at Sunium there are only sixteen flutes; the flutes were elliptic in section and intersected with an arris. In order to correct an optical illusion, which arises in a diminishing shaft, a slight entasis or swelling in the centre was given, the greatest departure from the straight line being about one-third up the shaft. The shaft was ornamented by the capital, the juncture of the two being marked by a groove, and in the Parthenon, but up to three in more ancient examples) known as the hypotrachelion. Above this the trachelion or necking curves over, constructing what is known as the apophyge up to the fillets, round the base of the echinus, which forms the transition to the square abacus. The varying curve of the echinus, from the earliest times down to the later examples, is shown in the article on mouldings. The relative proportions of the lower diameter and the height of the columns vary according to the date of the example, in the early examples the column being just on 4 diameters high, in the Parthenon nearly 5¾ diameters, and in the Temple of Jupiter Nemaeus 6¾ diameters high. The distance between the columns or intercolumniation varied also according to the date, that of the earliest examples in Sicily being about 1 diameter (that between the angle columns being always less), in the Parthenon in the proportion of 1 to 1:24, and in the temple at Argos as 1 to 1:53.

Above the columns rested the entablature (fig. 2), of which the lower member, the architrave, was plain and crowned by a projecting fillet, known as the regular; under which, and below the triglyph, was a fillet (taenia), with six guttae underneath. The proportional height of the architrave, which was the chief supporting member, varied according to date, in one of the earliest examples at Syracuse being of greater depth than the diameter of the column, and in the Parthenon about two-thirds of the diameter. Above the architrave was the frieze, divided into triglyphs, so called because they are divided into three bands by two vertical grooves, and metopes or spaces between the triglyphs. It is known that the triglyphs represented the beams in the primitive cella before the peristyle was added, the spaces between being filled with shutters or boards to prevent the temple being entered by birds. The face of the metopes, which are nearly square, is set back behind that of the triglyphs, and is sometimes decorated with sculpture in high relief. There is generally one triglyph over each column and one between, but at each end of the temple there is a triglyph at the angle, so that the intercolumniation of the angle columns is less than that of the others, which gives a sense of increased strength. Above the frieze is the cornice, which projects forward about one-third of the diameter of the column and slopes downwards at an angle generally the same as the slope of the roof. On its under surface are mutules, one over each triglyph and one between, which are studded with guttae, probably representing the wood pins which secured the rafters in their position generally speaking, in the Doric temples there is no cymatium or gutter, and the rain fell directly off the roof; in order to prevent it trickling down there was an upper moulding, throught, with a bird's beak moulding behind and a second throrating near the bottom, so that the corna had an upper fillet projecting, and a lower fillet receding, from its fascia plane. The roof itself was covered with tiles in terra-cotta or marble, which consisted of flat slabs with raised edges and covering tiles over the joints; the lower ends of the covering tiles were decorated with antefixae, and the top of the roof was protected by ridge tiles, on the top of which was a beak or beakwork.
which were sometimes additional antefixae placed parallel with the ridge tile. As the mouldings of the pediment were returned for a short distance along the side, there was a small cymatium or gutter with lions' heads, through the mouth of which the water ran. In the principal and rear front of the temple the lines of the cornice were repeated up the slope of the pediment, which coincided with that of the roof, and the tympanum, which they enclosed, was enriched with sculpture. On the centre of the pediment and at each end were pedestals (acroteria), on which figures, or conventional ornaments, were placed. Supplementary to the order at the back of the peristyle were antae, slightly projecting pilasters which terminated the walls of the pronaos; these had a small base, were of the same diameter from the top to the bottom, and had a simple moulded capital.

The Greek Ionic Order.—The Ionic order, like the Doric, owes its origin to timber prototypes, but varies in its features; the columns are more slender, being from 8 to 9 diameters high, with an intercolumniation of sometimes as much as 2 diameters; the architrave also is subdivided into three fascia, which suggests that in its origin it consisted of three beams superposed, in contradistinction to that of the Doric architrave, which consisted of a single beam. As in the Doric order, the Ionic temple rested on a stylobate of three steps (fig. 3). The columns consisted of base, shaft and capital. In the actual examples of the base consisted of a torus moulding projected horizontally, beneath which were three double astragals divided by the scotia, sometimes, as in the temple at Priene, resting on a square plinth. In the Attic base employed in Athens, under the upper torus, which is either plain, fluted or carved with the guilloche, is a fillet and deep scotia, with a second torus underneath. The shaft tapers much less than in the Doric order; it has a slighter entasis, and is fluted, the flutes being elliptical in section but subdivided by fillets. The number of flutes is generally 24. The lower and upper parts of the shaft have an apophyge and a fillet, resting on the base in the former case and supporting the capital in the latter. The capital consists of an astragal, sometimes carved with the bead and reel, and another moulding above, enriched with the egg-and-dart, on which rests the capital with spiral volutes at each end, and from front to back with cushions which vary in design and enrichment. In the capitals of the angle columns the end volute is turned round on the diagonal, so as to present the same appearance on the front and the side; this results in an awkward arrangement at the back, where two half-volutes intersect one another at right angles. A small abacus, generally carved with ornament, crowns the capital. In early examples the channels between the fillets of the spiral are convex, in later examples concave. In the capitals of the Erechtheum (fig. 4), a greater richness is given by intermediate fillets. In all great examples the second fillet dips down in the centre of the front and a small anthemion ornament marks the receding of the echinus moulding, which is circular and sometimes nearly merged into the cushion. In the Erechtheum the enrichment of the capital is carried further in the necking, which is decorated with the anthemion and divided off from the upper part of the shaft by a bead and reel. The entablature is divided, like that of the Doric order, into architrave, frieze and cornice. The architrave is subdivided into three fasciae, the upper one projecting slightly beyond the lower, and crowned by small mouldings, the lower one sometimes carved with the Lesbian leaf. Above this is the frieze, sometimes plain and at other times enriched with figure sculpture in low relief. In the Ionic examples there was no frieze, its place being taken by dentils of great size and projection. The cornice consists of bedmould, corona and cymatium; in the Ionic examples the bedmould is of great richness, consisting of a lower moulding of egg-and-dart with bead and reel, a dentil course above, and another egg-and-dart with bead and reel above, sinking into the sofit of the corona, which projects in the Ionic examples more than half a diameter. The corona consists of a plain fascia with moulding and cymatium above, and as the cymatium or gutter is carried through from end to end of the temple it is provided with lions' heads to throw off the water, and sometimes enriched with the anthemion ornament. In the Attic examples much greater simplicity, ascribed to Doric influence, is given to the bedmould, in which only the cymatium is similar to the Lesbian leaf carved on it and the bead and reel are retained. The mouldings of the cornice, including the cymatium, are carried up as a pediment, as in the Doric temple, and the roofs are similar. The base and capital of the antae are more elaborate than in those of the Doric order, and are sometimes, both in Ionic and Attic examples, richly carved with the Lesbian leaf and egg-and-dart, in both cases with the bead and reel underneath. The chief variation from the usual entablature is found in that of the caryatide portico of the Erechtheum, where the frieze is omitted, dentils are introduced in the bedmould, paterae are carved on the upper fascia of the architrave, and the covering was a flat marble roof. The caryatide figures, the drapery of which recalls the fluting of the columns, stood on a podium which enriched cornice and base.

The Greek Corinthian Order (fig. 5).—As the entablature of this order was adapted by the Greeks from that of the Ionic order, the capital only need be described, and its evolution from the earliest examples known, that in the temple at Bassae, to the fully developed type in the temple of Zeus Olympius at Athens, can be easily traced. It consisted of either a small range of leaves at the bottom, or of a bead-and-reel moulding, a bell decorated in various ways and a moulded abacus, the latter as a rule being concave in plan on each face and generally terminating in an arris or point. In the Bassae capital we find the first example of the spiral tendrils which rise up to and support the abacus with other spirals crossing to the centre and the acanthus leaf and flower. In the more perfected example of the Choragic
monument of Lysicrates (fig. 6), there is a lower range of small leaves of some river plant, between which and the tops of the flutes (which here are turned over as leaves) is a sinking which was probably filled with a metal band. From the lower range of leaves spring eight acanthus leaves, bending forward at the top, with small flowers between, representing the heads of nails which in the metal prototype fastened these leaves to the bell; from the caiiculae, on the right and left, spring spiral tendrils rising to the angles under the abacus, and from the same caiiculae double spirals which cross to the centre of the bell, the upper ones carrying the anthemion flower, which rises across the abacus. The abacus in this capital has a deep scotia with fillet, and an echinus above, and is one of the few great examples in which the angles are canted. The architrave, frieze and cornice are adaptations from the Ionic order. The corona has in the place of the cymatium a cresting of antefixae, which is purely decorative, as there are no covering tiles, the roof of the monument being in one block of marble carved with leaves. Set back and on the same plane as the architrave and frieze is a second cresting with the Greek wave scroll. There are other types of Greek Corinthian capital, of which the finest example is in the interior of the Tholos at Epidaurus (c. 400 B.C.), with two rows of leaves round the lower part, angle and central spirals, and a flower in the centre of the abacus. Of other examples the capitals of the interior of the temple of Apollo Branchidae in Asia Minor, and of the vestibule at Eleusis, and of the two porches of the temple of the Winds at Athens, are the best known. Except for the pointed ends of the abacus, which are Greek, the capital of the temple of Zeus Olympus might almost be classed among the Roman examples, and it is thought to have been the model copied by the Romans from those which Sulla took to Rome for the temple of Jupiter Capitolinus.

The Roman Doric Order.—The earliest example of this order is probably that of the temple at Cora, about 20 m. from Rome, attributed to Sulla (80 B.C.), in which the leading features of the Greek Doric order are employed, but extremely degraded in style. The temple was raised on a podium with a flight of steps in front; the shaft has 20 flutes and is carried on a small torus base, and the echinus of the capital is very poor. The architrave and triglyph-frieze are cut out of the same stone, the former being much too shallow to allow of its carrying the frieze and cornice. Two other early examples are those employed in the decoration of the arcades of the Tabularium and of the theatre of Marcellus (fig. 5); they are only semi-detached. The Doric order was not a favourite with the Romans, and did not appeal to their tastes for rich decoration; the only other examples known are those at Praeneste, at Albano, and in the temple of Diocletian. At Albano the echinus of the capital is carved with the egg and anchor, and in the thermae a cyma-recta carved with a leaf ornament takes the place of the echinus. There is no base to any of these examples, the Albano base consisting only of an apophyge and fillet, and only the Diocletian example is fluted.

The Roman Ionic Order.—The complete degradation of the Ionic order is clearly shown in the so-called temple of Fortuna Virilis (ascribed to about 100 B.C.), in the profuse decoration of architrave, frieze and cornice with coarse ornament, and, in the capital, the raising of the echinus to the same level as the top of the second fillet of the volute, so that it is no longer visible under the cushion. The shaft has twenty flutes, the fillet being much wider than in the Greek examples, and the flute is semicircular. Much more refinement is shown in the order as employed on the upper storey of the theatre of Marcellus (fig. 6), where the only part enriched with ornament is in the egg and tongue of the bed-mould. In the capital the fillet of the volute runs across above the echinus, and the canalis is stopped at end over the volute, an original treatment. The most corrupt example of the Roman Ionic capital is that of the temple of Saturn on the Forum Romanum, which fortunately does not seem to have been copied later. The base of all the Roman Ionic columns is that known as the Attic base, viz. a lower and upper torus with scotia and fillets between, always raised on a square plinth.

The Roman Corinthian Order.—The great varieties of design in the Greek Corinthian capital (fig. 7), and the fact that its entablature was copied from Ionic examples, suggests that no definite type sufficient to constitute an order had been evolved by the Greeks; it remained therefore a problem to be worked out by the Romans, who, with the assistance of Greek artists,
employed generally by the Romans, not only in Rome but throughout Greece, Asia Minor and Syria, developed an order which, though wanting in the refinement and subtlety found in Greek work, is one of the most monumental kind, and has in its adoption by the Italian revivalists had more influence than any other in the raising of palatial structures. Even in Rome itself the portico of the Pantheon, erected by Agrippa (27 B.C.), and the temple of Castor (rebuilt by Domitian A.D. 86) in the Forum, are remarkable instances of early work, which hold their own with some of the later examples even of Greek art.

The development of the Roman Corinthian order will be best understood by a description in detail similar to that given of the great Doric and Ionic orders. Taking the Pantheon portico as the earlier example, the base consists of an upper and a lower astragal, separated by a double astragal with scotia and fillet above and below, and resting on a square plinth. The shaft, a monolith, is unfluted, tapering upwards, 9\(\frac{1}{2}\) diameters in height, with apophyge and fillet at the bottom, and an apophyge, fillet and astragal at the top. The capital consisted of a square abacus with concave sides carried on a circular inverted bell, two rows of anthemion leaves, rising three-fifths of the bell, being carved round it (fig. 10), the stems of the upper range of eight leaves lying in the axis of each face and of the diagonals, and those of the lower range between them; the stems of the caulicolae from which spring the spirals, which rise to support the angles of the abacus, and to the centre of the capital, carrying the central flower, start from between the upper range of leaves. The abacus has concave sides, canted angles, and is moulded, with a quarter round, fillet and cavetto. The architrave, like that of the Greek Ionic order, has three fasciae, but they are further elaborated by a small cyma-reversa under the upper fascia and a bead under the second fascia. The architrave is crowned with a moulding, consisting of a fillet with cyma-reversa and bead underneath. The frieze is plain, its only decoration being the well-known inscription of Agrippa. The bedmould consists of a beaded, cyma-reversa and fillet, under a plain dentil course, in which the dentils are not carved; bead-and-reel and egg-and-dart above these carried a plain face on which is found the new feature introduced by the Romans, viz. the modillion. This, though carved out of one solid block with the whole bedmould, suggested an appropriate support to the projecting cornice. The modillion was a bracket, a horizontal version of the ancones which supported the cornice of the Greek doorway cornice, and was here crowned by a small cyma-reversa carved with leaves which profiled round the modillion and along the upper part of the plain face. The cornice is simple, consisting of a corona, fillet and cymatium, the latter omitted across the front of the temple, but carried up over the cornice of the pediment. All the columns are equidistant with an intercolumniation of 2\(\frac{1}{2}\) diameters. The order of the interior of the rotunda built by Hadrian (A.D. 121) is similar to that of the portico, the lower moulding of the bedmould and the bead being carved, and the tongue or anchor taking the place of the dart between the eggs.

The order of the temple of Castor (fig. 11) was enriched to a far greater extent, and parts were carved with ornament, which Greek examples was probably only painted. The base was similar, but the columns (10 diameters high) had twenty-four flutes, with fillets between. The capital was further enriched with foliage, which rising from the caulicolae was carried along the cavetto of the abacus, whose upper moulding was carved with the egg-and-dart. The middle fascia of the architrave was carved with a version of the Greek anthemion, the cyma-reversa under the upper fascia being carved with leaves and bead-and-reel under. The lower moulding of the bedmould was carved with the egg-and-tongue; the dentil course was carved with finely proportioned dentils, the cyma-reversa and mouldings above being similar to those of the Pantheon portico. In the latter, on the soffit of the corona, square panels are sunk with a flower in the centre. In the temple of Castor the panel is square, but there is a border in front and back, which shows that the cornice had a greater projection. The corona was carved with fluting, departing from the simplicity of the Pantheon example, but evidently more to the taste of the Romans, as it is found in many subsequent examples. The intercolumniation is only two and one-third of the diameter. Though not quite equal to Greek foliage, that of the capitals of the temple of Castor is of great beauty, and there is one other feature in the capital
which is unique; the spirals of the centre are larger than usual and interlace one another. A variety of the bedmould of the cornice is found in the so-called Temple of the Sun on the Quirinal Hill; although of late date, the entablature has the character of the Renaissance of the Augustan era, so fine and simple are the capitals examples. The architrave, of its half-way cornice which is about 1 ft. high in one-half the aisles, was found in the interior of Trajan's basilica; in Asia Minor at Aizani (1st century A.D.) a single row of leaves was employed round the capitals of the pronaoi under the volutes of an Ionic capital; the architect of the Arch of Titus (A.D. 81) went one step farther and introduced the double row of leaves; both examples exist in the Arch of Septimus Severus (fig. 12), in the tepidarium of the thermae of Diocletian, and, to judge by the numerous examples still existing in the churches at Rome, it would seem to have been the favourite capital. The Byzantine architects also based most of their capitals on the Roman Composite examples. There are other hybrid Roman capitals, in which figures of a winged Victory, rams' heads or cornucopias, take the place of the angle spirals of the Corinthian capital.

The Arcade Order.—This, which was defined by Fergusson as the true Roman order, is a compound of two distinct types of construction, the arcuated and the trabeated, the former derived from the Etruscans, the latter from the Greeks. Whilst, however, the arcade was a constructive feature, the employment of the semi- or three-quarter detached column with its entablature complete, as a decorative screen, was a travesty of its original constructive function, without even the excuse of its adding in any way to the solidity of the structure, for the whole screen could be taken off from the Roman theatres and amphitheatres without in any sense interfering with their stability. The employment of the attached column only, as a vertical decorative feature subdividing the arches, might have been admissible, but to add the entablature was a mistake, on account of the intercolumniation, which was far in excess of that employed in any order, so that not only was it necessary to cut the architrave into voussoirs, thus forming a flat arch, but the stones composing it had to be built into the wall to ensure their stability; the entablature thus became an element of weakness instead of strength (fig. 13). The earliest example of the Arcade order is the Tabularium in Rome (80 B.C.) where it was employed to light a vaulted corridor running from one end to the other of the structure and raised some 50 ft. from the ground. The column is semi-detached, 7½ diameters high with an intercolumniation of nearly 4 diameters, and an entablature with an architrave which is less than half a diameter, quite incapable, therefore, of carrying itself, much less than the rest of the entablature; the impost pier of the arch is a diameter, and the height of the open arcade a little more than half its width. The shaft

Fig. 12.—The Composite Order; Arch of Septimus Severus.
semi-detached columns of the Ionic order, and these are found in the upper storey of the theatre of Marcellus, the earliest example existing of the superposed orders. A certain proportion exists between the orders employed; thus the upper diameter of the Doric column (which is \(\frac{3}{5}\) diameters high with a diminution of between one-fifth and one-sixth of the lower diameter) is the same as the lower diameter of the Ionic column, which is \(\frac{3}{8}\) diameters high and a much slighter diminution. In the Colosseum and Palladio, the former in France and the latter in England, the dates of the publication of their works being 1563 and 1570 respectively. In 1759 Sir William Chambers published a treatise on civil architecture, in which he set forth his interpretation of the five orders, and his treatise is still consulted by students. They all of them based their conjectural restorations on the descriptions given by Vitruvius, who, however, avoids using the same term throughout, the words genus, ratio, species, mores being employed, from which it may be concluded that the Greeks themselves had no such term as that which is now defined as "order," especially as in his book he invariably quotes the Greek name when describing various parts of the temple. In the preface to the fourth book he speaks only of the three orders (genus), so that the Tuscan described in Book IV. chap. vii. would seem to have been an afterthought, and his description of the entablature shows that it was entirely in wood and therefore an incomplete development. The Italian revivalists, however, evolved one of their orders out of it and added a fifth, the Composite, of which there was no example in Rome before A.D. 82. In the description which follows it must be understood that it refers only to the Italian version of what the revivalists considered the Tuscan orders to consist of, and Vignola's interpretation will be given, because he seems to have kept closer to Vitruvius's descriptions and to have taken as his model the finest examples then existing in Rome.

The Tuscan Order.—The base consists of a torus moulding, resting on square plinths; the shaft is terminated below by an apophyge and fillet and tapers upwards, the diminution being between one-quarter and one-fifth of the lower diameter, with an apophyge, fillet and astragal at the top, the capital consists of a square abacus with fillet and cavetto, an echinus, fillet and a necking; the whole column being 7 diameters high. The intercolumniation given by Vignola is \(\frac{3}{4}\) diameters, instead of the \(\frac{3}{5}\) diameters of Vitruvius's acrostyle. The architrave, frieze and cornice, are simple versions of the Doric, except that there are no triglyphs in the frieze.

The Doric Order.—In his Doric order Vignola has followed the Roman Doric order of the theatre of Marcellus, but he gives it a base consisting of an astragal and torus resting on a square plinth; in his shaft he copies the fluting (24 flutes) with the area of the columns of the thermes of Diocletian; his capital, except the flowers decorating the necking and his entablature, are entirely taken from the theatre of Marcellus; in a second study he introduces an Attic base, carves the echinus of the capital with the egg-and-tongue, introduces two fasciae in his architrave, and to support the cornice provides shallow plain modillons with guttae on the soffits. In both the examples given the columns taper upwards and are 8 diameters high.

The Ionic Order.—For the Ionic order Vignola discards the temple of Fortuna Virilis, but enriches the order of the theatre of Marcellus, adopting the base of the temple of Castor and the fluted columns of the same; in his frieze he introduces that of the Corinthian temple of Antoninus and Faustina, and in the bedmould and cornice copies that of the thermes of Diocletian. Palladio in his entablature introduces the convex friezes and adopts a single uncarved modilion under the cornice. In both cases the columns are fluted and 5 diameters high.

The Corinthian Order.—In this order Vignola, for his base, returns to the temple of Castor, makes his columns 10 diameters high, copies the capital of the portico of the Pantheon, introduces a rib frieze with winged female figures and a bull about to be sacrificed, and adopts the bedmould of the temple of Castor, reversing the carving of two of the mouldings and the cornice, and omitting the fluting of the corona of that temple. In Palladio's Corinthian order the frieze is too narrow and the bedmould, though copied from the temple of Castor, is of smaller scale.

The Composite Order.—As in the Roman Composite order the only original feature was the capital, there were no new versions to be given of the entablature, but unfortunately they were unable to copy the many examples in Rome. In the three best-known capitals, those of the arches of Titus and Septimus
Severus and in the thermae of Diocletian, the upper fillet of the volute runs straight across the capital, being partially sunk in the cavetto of the abacus; in the canalis of the volutes of all these examples is a band of foliage which dips down to carry the centre flower, and, on account of its projection, it hides, from those looking only from below, the upper fillet of the volute. The architects of the Revival, therefore, in their studies of the capital, turned the volutes (which they would seem, like Ruskin, to have thought were horns) down on to the top of the echinus, producing a composition which is not in accordance with ancient examples and shows ignorance of the origin and development of the Ionic volute; unfortunately their interpretations of the Composite capital were followed by Inigo Jones, and are employed even in Regent Street, London, at the present day; there are, however, two or three Renaissance examples in Paris, in which the true Composite capital has been retained.

The Pedestal.—The architects of the Revival would seem to have conceived the idea that no order was complete without a pedestal. The only Roman examples of isolated columns with pedestals known are those of the columns of Trajan, Marcus Aurelius, Antoninus Pius and others of less importance, but they carried statues only and had no structural functions as supports to an entablature; the pedestals under the columns which decorated the arches of triumph were built into and formed part of the structure of the arch. The columns of the tepidarium of the Roman thermae had pedestals of moderate height (about 3 to 4 ft.) which bore no proportional relation to the diameter of the column. Vignola, however, gave definite proportions for the pedestal, which in the Doric order was to be 2 diameters in height, in the Ionic 2½ diameters, and in the Corinthian order 3 diameters, the result being that in the front of the church of St John Lateran, where the Corinthian pilasters are of great height, the pedestals are 12 to 13 ft. high. In conjunction with the arcade there was more reason for pedestals to the semi-detached columns on the upper storeys, but none was employed on the ground storey, either in the theatre of Marcellus or in the Colosseum.

ORDER, HOLY. “Holy Orders” (ordines sacri) may be defined as the rank or status of persons empowered by virtue of a certain form or ceremony to exercise spiritual functions in the Christian church. Thus Tertullian (Idol. 7, Monog. 11) mentions the “ecclesiastical order,” including therein those who held office in the church, and (Exhort. Cast. 71) he distinguishes this ordo from the Christian plebs or laity. We may compare the common use of the word ordo in profane writers, who refer, e.g., to the ordo senatorius, ordo equester, &c. It is true that the evidence of Tertullian does not carry us back farther than the close of the 2nd or opening of the 3rd century A.D. But a little before Tertullian, Irenaeus, though he does not use the word ordo, anticipates in some measure Tertullian’s abstract term, for he recognizes a magisterii locus, “a place of magistracy” or “presidency” in the church. Indeed, phrases more or less equivalent occur in the sub-apostolic literature, and even in the New Testament itself, such as those who are “over you in the Lord” (1 Thess. v. 12), those “that bear the rule” (Heb. xiii. 7; cf. 1 Clem. i. 3; Herm. Vis. ii. 2, 6). Here we pause to remark that in Tertullian’s view the church as a whole possesses the power of self-government and administration, though in the interest of discipline and convenience it delegates that power to special officers. It is, he says, the “authority of the church” which has constituted the difference between the governing body and the laity, and in an emergency a layman may baptize and celebrate (Exhort. Cast. 7), nor can this statement be lightly set aside on the plea that Tertullian, when he so wrote, had lapsed into Montanism. The fact is that the Montanists represented the conservatism of their day, and even now the Roman Church admits the right of laymen to baptize when a priest cannot be had. The Apostolic Constitutions (viii. 32).
ORDER, HOLY

allow a layman to preach, if he be skilful and reverent, and the language of St Ignatius (Ad Smyrn. 8), "Let that be esteemed a valid Eucharist which is celebrated in the presence of the bishop or of some one commissioned by him," is really inconsistent with any firmly established principle that celebration by a layman was in itself absolutely null (see Eucharist).

When we go on to inquire what special offices the church from the beginning, or almost from the beginning, adopted and recognized, two points claim preliminary attention. In the first place, much would be done in practical administration by persons who held no definite position formally assigned to them, although they wielded great influence on account of their age, talents and character. Next, it must be carefully remembered that the early church was, in a sense for us even to understand, ruled and edified by the direct action of the Holy Spirit. St Paul (1 Cor. xii. 28) furnishes us with a list of church offices very different from those which obtain in any church at the present day. 

"God," he says, "hath set some in the church, first apostles, secondly prophets, thirdly teachers, then miracles, then gifts of healing, helps, governments, (divers) kinds of tongues." Ministry of this sort is not to be confounded with "order," of which this article treats. It died out very gradually, and the Didache or Teaching of the Apostles, compiled probably between A.D. 130 and 160, gives clear information on the nature of this prophetic or charismatic ministry. The title of "apostle" was limited to the immediate disciples of our Lord but it was given to missionaries or evangelists who went about founding new churches; the prophets spoke by revelation; the teachers were enabled by supernatural illumination to instruct others.

All of these men were called to their work by the internal voice of the Holy Spirit: none of them was appointed or elected by their fellows: none of them, and this is an important feature, was necessarily confined to a local church. Nevertheless, side by side with this prophetic ministry there was another, mediatly at least of human appointment, and local in its character. Here we have the germ of orders in the technical sense. At first this local ministry was twofold, consisting of presbyters or bishops and deacons. Christian presbyters first appear (Acts xiii. 30) in the church of Jerusalem, and most likely the name and office were adopted from the Jewish municipalities, perhaps from the Jewish synagogues (see Priest). Afterwards St Paul and St Barnabas in their first missionary journey "appointed" (Acts xiv. 23) presbyters in every church. Further, we find St Paul about A.D. 62 addressing the "saints" at Philippi "with the bishops and deacons." The word ἔπισκοπος or overseer may be of Gentile origin, just as presbyter may have been borrowed from the Jews. There is strong proof that presbyter and episcopus are two names for the same office. It has indeed been maintained by eminent scholars, chiefly by Hatch and Harnack, that the word episcopus was given originally to the chief officer of a club or a confraternity, so that the episcopus was a financial officer, whereas the presbyters regulated the discipline. To this it may be objected that presbyters and bishops are never mentioned together, and that the names were interchangeable (Acts xx. 17 and 28; 1 Pet. v. 1, 2; 1 Tim. iii. 1-7 and v. 17-19; Tit. i. 5-7). The work of the presbyter or bishop was concerned at first with discipline rather than with teaching, which was largely in the hands of the charismatic ministry; nevertheless, the Pastoral Epistles (1 Tim. iii. 2) insist that an episcopus must be "apt to teach," and some presbyters (1 Tim. v. 17) not only ruled but also "laboured in the word and in teaching." They also "offered the gifts " (1 Clem. 44), i.e. to adopt Bishop Lightfoot's interpretation, "they led the prayers and thanksgivings of the congregation, presented the alms and contributions to God and asked His blessing on them in the name of the whole body." Under the bishops or presbyters stood the deacons or "helpers" (Philipp. i. 1, 1 Tim. iii. 8-13). Whether they were the successors, as most of the Fathers believed, of the seven chosen by the church of Jerusalem to relieve the apostles in the administration of alms (Acts vi.) is a question still disputed and uncertain. Be that as it may, the deacon was long considered to be the "servant of the widows and the poor." (Jerome, Ep. 146), and the archdeacon, who first appears towards the end of the 4th century, owes the greatness of his position to the fact that he was the chief administrator of church funds (see Archdeacon). This ancient idea of the diaconate, ignored in the Roman Pontifical, has been restored in the English ordinal. The growth of sacerdotal theories, which were fully developed in Cyprian's time, fixed attention on the bishop as a sacrificing priest, and on the deacon as his assistant at the altar.

Out of the twofold grew the threefold ministry, so that each local church was governed by one episcopus surrounded by a council of presbyters. James, the Lord's brother, who, partly because of his relationship to Christ, stood supreme in the church at Jerusalem, as also Timothy and Titus, who acted as temporary delegates of St Paul at Ephesus and in Crete, are justly considered to have been forerunners of the monarchical episcopate. The episcopal rule in this new sense probably arose in the lifetime of St John, and may have had his sanction. At all events the rights of the monarchical bishop are strongly asserted in the Ignatian epistles (about A.D. 110), and were already recognized in the contemporary churches of Asia Minor. We may attribute the origin of the episcopate to the need felt of a presiding officer to preside at the Eucharist, to represent the church before the magistrate and in the face of rising heresy, and to carry on correspondence with sister churches. The change of constitution occurred at different times in different places. Thus St Ignatius in writing to the Romans never refers to any presiding bishop, and somewhat earlier Clement of Rome in his epistles to the Corinthians uses the terms presbyter and episcopus interchangeably. Hermas (about A.D. 140) confirms the impression that the Roman Church of his day was under presbyteral rule. Even when introduced, the monarchical episcopate was not thought necessary for the ordination of other bishops or presbyters. St Jerome (Ep. 146) tells us that as late as the middle of the 3rd century the presbyters of Alexandria, when the see was vacant, used to elect one of their own number and without any further ordination set him in the episcopal office. So the canons of Hippolytus (about A.D. 250) decree that a confessor who has suffered torment for his adherence to the Christian faith should merit and obtain the rank of presbyter for such "Immo confesso est ordinatione ejus." Likewise in A.D. 314 the thirteenth canon of Anzera (for the true reading see Bishop Wordsworth's Ministry of Grace, p. 140) assumes that city presbyters may with the bishop's leave ordain other presbyters. Even among the medieval schoolmen, some (Gore, Church and Ministry, p. 377) maintained that a priest might be empowered by the pope to ordain other priests.

The threefold ministry was developed in the 2nd, a sevenfold ministry in the middle of the 3rd century. There must, says Cornelius (apud Euseb., H. E. vi. 43), be one bishop in the Catholic Church; and he then enumerates the church officers subject to himself as bishop of Rome. These are 46 presbyters, 7 deacons, 7 subdeacons, 42 acolytes, 52 exorcists and readers, together with doorkeepers. The subdeacons, no doubt, became a necessity when the deacons, whose number was limited to seven in memory of their original institution, were no longer equal to their duties in the "regions" of the imperial city, and left their lower work, such as preparation of the sacred vessels, to their subordinates. The office of acolyte may have been suggested by the attendant assigned to heathen priests. The office of doorkeeper explains itself, though it must be remembered that it was the special duty of the Christian ostiarius to exclude the unbaptized and persons undergoing penance from the more solemn part of the Eucharistic service. But readers and exorcists claim

1 A partial exception may be made in favour of the "Catholic Apostolic Church" founded by Edward Irving.

2 Josephus, e.g. Antiq. vi. 4. 2, abundantly justifies this translation.
ORDER, HOLY

185

special notice. The reader is the only minor official mentioned by Tertullian (Præser. 41). An ancient church order which belongs to the latter part of the 2nd century (see Harl. and Sources of Apostolic Canons, Eng. Transl. p. 54 seq.) mentions the reader before the deacon, and speaks of him as filling "the place of an evangelist." We are justified in believing that both exorcists and readers, whose functions differed essentially from the mechanical employments of the other minor clerics, belonged originally to the "charismatic" ministry, and sank afterwards to a low rank in the "orders" of the church (see Exorcist and Lector). There were also other minor orders in the ancient church which have fallen into oblivion or lost their clerical character. Such were the copiatae or grave-diggers, the psalmistae or chanters, and the parabolani, who at great personal risk—whence the name—visited the sick in pestilence. The modern Greek Church recognizes only two minor orders, viz. those of subdeacons and readers, and this holds good of the Oriental churches generally, with the single exception of the Armenians. The Anglican Church is content with the threecfold ministry of bishops, priests and deacons, but in recent times the bishops have appointed lay-readers, licensed to read prayers and preach in buildings which are not consecrated. The Latins, and Armenians who have borrowed from the Latins, have subdeacons, acolytes for exorcists, readers and chanters. Since 1379, at the Council of Constance, the Latin Church has placed the subdeacon among the greater or sacred orders, the subdeacon being obliged to the law of celibacy and bound to the daily recitation of the breviary offices. The minor orders, and even the subdiaconate and diaconate, are now regarded as no more than steps to the priesthood. Roman theologians generally reckon only seven orders, although, if we count the episcopate an order distinct from the presbyterate, the sum is not seven, but eight. The explanation given by St Thomas (Suppl. xi. 5) is that, whereas all the orders have reference to the body of Christ present on the altar, the episcopate, so far forth, is not a separate order, since a simple priest no less than a bishop celebrats the Eucharist. The Council of Trent takes the same view; it enumerates (Sess. xxiii. cap. 2) only seven orders, and yet maintains (cap. 4) the ecclesiastical hierarchy of bishops, priests and ministers, the bishops as successors of the Apostles holding the highest place. The Roman Church forbids ordination to higher grades unless the candidate has received all the inferior orders. Further, a cleric is bound to exercise the minor orders for a year before he can be ordained subdeacon; he must be ordained subdeacon for a year before he is ordained deacon for a year before he is made priest. However, instances of men elevated at once from the condition of laymen to the priesthood were known in the early church, and Chardon (Hist. des sacrements, vol. v. part 1, ch. v.) shows that in exceptional cases men were consecrated bishops without previous ordination to the priesthood.

Passing to the effect of ordination, we meet with two views, each of which still finds advocates. According to some, ordination simply entitles a man to hold an office and perform its functions. It corresponds to the form by which, e.g., a Roman official was put in possession of his magistracy. This theory is clearly stated by Cranmer: "In the New Testament he that is appointed bishop or priest needed no consecration, by the Scripture, for election or appointment thereto is sufficient." This view, widely held among modern scholars, has strong support in the fact that the words used for ordination in the first three centuries (κατακολουθείν, καθαρτισμόν, κηρυσσεῖν, constitui, ordinare) also expressed appointment to civil office. Very different is the medieval theory, which arose from the gradual acceptance of the belief that the Jewish was the prototype of the Christian priest. According, then, to the Roman view,

2 Cranmer's works are to be found in Burnet, "Collection of Records," appended to his History of the Reformation (ed. Pocock), iv. 478. Cranmer also maintained that "bishops and priests are but both one office in the beginning of Christ's religion," ib. p. 471.

3 This word is a sacrament, and as such instituted by Christ;it confers grace and power, besides setting a mark or character upon the soul, in consequence of which ordination to the same office cannot be reiterated. Such is the teaching of the Roman Church, accepted by the Greeks and with certain modifications by Anglicans of the High Church school, who appeal to 1 Tim. iv. 14, 2 Tim. i. 6. We may conclude with brief reference to the most important aspects of the Roman doctrine.

The ordinary minister of orders is a bishop. The tonsure and minor orders are, however, still sometimes conferred by abbots, who, though simple priests, have special faculties for the ordination of their monks. Some account has been already given of scholastic opinion on presbyteral ordination to the diaconate and even to the priesthood. Can a heretical or schismatical bishop validly ordain? Is a simoniacal ordination valid? All modern theologians of the Roman Church answer these questions in the affirmative, but from the 8th to the beginning of the 13th century they were fiercely agitated with the utmost diversity of opinion and practice. Pope Stephen reconsecrated bishops consecrated in the usual way by his schismatical predecessor Constantine. Pope Nicholas declared orders given by Photius of Constantinople null. St Peter Damian was grievously perplexed about the validity of simoniacal ordinations. Similarly, the Council of Lateran held that degradation deprived a priest of power to consecrate. St Thomas, on the other hand, considered that "heretics and persons cut off from the church" (Summ. Suppl. xxxvii. 2) may ordain validly, and that a priest who has been degraded can still celebrate the Eucharist (Summ. iii. 82. 8) validly, though of course not lawfully. This opinion, defined by Bonaventure, Alexander of Hales, Scotus and others, soon became and is now generally accepted.

The Schoolmen had no historical sense and little historical information; hence they fell into one error after another on the essentials in the rite of ordination. Some of them believed that the essential matter in the consecration of a bishop consisted in the placing the book of the gospels on his head and shoulders. True, this rite was used both in East and West as early as the 4th century; it was not, however, universal. According to common opinion, the matter and form of ordination to the episcopate were the imposition of the consecrating bishop's hands with the words, "Receive the Holy Ghost." The words in question, and indeed any imperative form of this kind, are still unknown to the East and were of very late introduction in the West. The final imposition of hands and the bestowal of power were not regarded as the sole effect of ordination. The reverse was the case, and the Roman Pontifical is later even than the tradition of instruments. For like reasons the tradition of the instruments, i.e. the handing over of paten and chalice in ordination to the priesthood, are admittedly non-essential, unless we adopt the opinion of some Roman theologians that our Lord left the determination of matter and form to the church, which has insisted on different rites at different times.

The necessity of reference to sacerdotal power in the ordination of priests and bishops will be considered a little farther on in connexion with Anglican orders.

Deaconesses in the East received the imposition of the bishop's hands, but could not ascend to the priesthood. The Roman theologians regard them as incapable of true ordination, alleging 1 Tim. ii. 12. An unbaptized person is also incapable of valid ordination. On the other hand, St Thomas holds that orders may be validly conferred on children who have not come to the use of reason. For lawful ordination in the Roman Church, a man must be confirmed, tonsured, in possession of all orders lower than that which he proposes to receive, of legitimate birth, not a slave or notably mutilated, of good life and competent knowledge. By the present law (Concil. Trib. Sess. xxiii. de Ref. in Ordin.) a subdeacon must have begun his twenty-second, a deacon his twenty-third, a priest his twenty-fifth year. The reality this is a survival of the primitive view that holy order is institution for an office which the local church confers and can therefore take away.

4 The canon law fixes the thirtieth year as the lowest age for episcopal consecration.
Council of Trent also requires that any one who receives holy orders must have a "title," i.e. means of support. The chief titles are poverty, i.e. solemn profession in a religious order, and the See of Peter. Holy orders are to be conferred on the Ember Saturdays, on the Saturday before Passion Sunday or on Holy Saturday (Easter Eve). The ancient and essential rule that a bishop must be "chosen by all the people" (Con. Hipp. ii. 7) has fallen into disuse, partly by the right of confirmation allowed to the bishops of the province, partly by the influence of Christian emperors, who controlled the elections in the capital where they resided, most of all by the authority exercised by kings after the invasion of the northern tribes and the dissolution of the empire (see Church History).

Such in brief were the doctrine and use of the early churches, gradually systematized, developed and transformed in the churches of the Roman obedience. The Reformation brought in radical changes, which were on the whole a return to the primitive type. Calvin states his views clearly in the fourth book of his Institutes, cap. iii. Christ, as he holds, has established in his Church certain offices which are always to be retained. First comes the order of priests or elders. These are subdivided into pastors, who administer the word and sacraments, doctors, who teach and expound the Bible, elders pure and simple, who exercise rule and discipline. The special care of the poor is committed to deacons. Ordination is to be effected by imposition of hands. The monarchical episcopate is rejected. This view of order was accepted in the Calvinistic churches, but with various modifications. Knox, for example, did away with the imposition of hands (McCrie's Knox, period vii.), though the rite was restored by the Scottish Presbyterian Church in the Second Book of Discipline. Knox also provided the Church of Scotland with superintendents or visitors, as well as readers and exhorters, offices which soon fell into disuse. Nor do Scottish presbyterians now recognize any special class of doctors, unless we suppose that these are represented by professors of theology. Independents acknowledge the two orders of presbyters and deacons, and differ from the Calvinistic presbyterians chiefly in this, that with them the church is complete in each single congregation, which is subject to no control of presbytery or synod.

Luther was not, like Calvin, a man of rigid system. He refused to look upon any ecclesiastical constitution as binding for all time. The keys, as he believed, were entrusted to the church as a whole, and from the church as a whole the "ministers of the word and sacraments" are to derive their institution and authority. The form of government was not essential. Provided that the preaching of the gospel was free and full, Luther was willing to tolerate episcopacy and even papacy. Hence the Lutheran churches exhibit great variety of constitution. In Scandinavia they are under episcopal rule. The Lutheran Bugenhagen, who was in priest's orders, ordained seven superintendents, afterwards called bishops, for Denmark in 1527, and Norway, then under the same crown, derives its present episcopate from the same source. Sweden stands in a different position. There three bishops were consecrated in 1528 by Peter Magnusson, who had himself been consecrated by a cardinal with the approval of the Roman Council of 1514, for the see of Westrid, to which he had been elected by the chapter. J. A. Nicholson (Apostolic Succession in the Church of Sweden, 1886) seems to have proved so much from contemporary evidence. A reply to Mr Nicholson was made in Swedish by a Roman priest, Bernhard, to whom Mr Nicholson replied in 1887. Unfortunately Mr Nicholson gives no detailed account of the form used in consecration, and on this and other points fuller information is needed. We may say, however, that Mr Nicholson has presented a strong case for the preservation of episcopal succession in the Swedish Church.

If the Swedish Church has preserved the episcopal succession, it does not make much of that advantage, for it is in communion with the Danish and Norwegian bodies, which can advance no such claim. On the other hand, the Church of England adhers closely to the episcopal constitution. It is true that in articles xix. and xxvi. she defines the church, without any express reference to the episcopate, as a "congregation of faithful men in which the pure word of God is preached and the sacraments be duly administered according to Christ's ordinances," and simply adds that the ordinal of Edward VI. for the consecration of bishops, priests and deacons, contains all that is necessary for such ordination and nothing which is of itself superstitious. The preface to the ordinal (1550) goes farther. Therein we are told that the threefold ministry of bishops, priests and deacons may be traced back to apostolic times, and in the final revision of 1662 a clause was added to the effect that no one is to be accounted "a lawful bishop, priest or deacon in the Church of England," unless he has had episcopal consecration or ordination. The words "in the Church of England" deserve careful notice. Nothing is said to condemn the opinion of Hooker (Eccl. Pol. viii. 14, 11) that "there may be sometimes very just and sufficient reason to allow ordination made without a bishop," or of the High Church Thornelip (apud Gibson in the Articles, i. 74), who "neither justifies nor condemns the orders of foreign Protestants." The church lays down a rule of domestic policy, and neither gives nor pretends to give any absolute criterion for the validity of ordination.

But while the Church of England has declined communion with non-episcopal churches, she has been involved in a long controversy with the Church of Rome in the validity of her own orders. It will be best to give first the leading facts, and then the inferences which may be drawn from them.

The English Church derives its orders through Matthew Parker, archbishop of Canterbury, who was consecrated in 1559 by William Barlow, bishop-elect of Chichester. We may assume that the rite employed was serious and reverent, and there is no longer any need to refute the fable of a ludicrous consecration at the "Nag's Head" tavern. We may further take for granted that Barlow was a bishop in the Catholic sense of the word. He had been nominated bishop of St Asaph in 1556, translated to St David's in the same year, and to Bath and Wells in 1547. He also sat in the upper house of Convocation and in the House of Peers. Now if Barlow all this time was not consecrated—and so far the only form of consecration known in England was according to the Roman rite—he would have incurred the penalties of praemunire, let alone the fact that Henry VIII. would not have tolerated such a defiance of Catholic order for a moment. The registers at St David's make no mention of his consecration, but this counts for nothing. No reference in the registers can be produced for many ordinations of undoubted validity. Parker thus was consecrated by a true bishop according to the Edwardine ordinal, i.e. he received imposition of hands with the words, "Take the Holy Ghost and remember that thou stir up the grace of God which is in thee by imposition of hands." The corresponding form for the ordination of a priest was "Receive thou the Holy Ghost: whose sins thou dost forgive," &c. These were the sole forms in use from 1553 to 1562.

Roman authorities have from the beginning and throughout consistently repudiated orders given according to the Edwardine ordinal. The case first came under consideration when Cardinal Pole returned to England early in Mary's reign with legatine authority for reconciling the realm to the Holy See. In his instructions to the bishops (Burnet Collect. pt. iii., bk. v., ch. 33; see also Dixon, Hist. Ch. of England, v. 238 seq.) he clearly recognizes orders schismatical but valid, i.e. those conferred in Henry's reign, and so distinguishes them by implication from invalid orders, i.e. those given according to the Edwardine book. In the former alone were "the form and intention of the church preserved." He could not doubt for a moment the utter invalidity of Edwardine ordinations to the priesthood. He knew very well that the theologians of his church almost without exception held that the handing over of the paten and chalice with the words, "Receive power of offering sacrifice," &c., were the essential matter and form of ordination to the priesthood; indeed he published the decree of Eugenius IV. to that effect

1 Compare also the article on Anglican orders in the Catholic Encyclopedia, vol. i., especially at p. 492.
ORDER IN COUNCIL

(The Anglican priesthood being gone, the episcopate also lapses. For according to the Pontifical, the episcopate is the "sumnum sacramentum"; the bishop in consecration receives "the sacerdotal grace"; it is "his office to ordain, ordain, offer, baptize, confirm." Thus in the Pontifical the words "Receive the Holy Ghost" are determined and defined by the context. There is nothing in the Anglican ordinal to show that the Holy Ghost is given for the consecration of a bishop in the Roman sense. In 1704 John Gordon, formerly Anglican bishop of Galloway, gave to the Holy Office an account of the manner in which he had been consecrated. The Sacred Congregation, with the pope's approval, declared his orders to be null. The constant practice has been to reorder unconditionally Anglican priests and deacons. In 1866 Leo XIII. summoned eight divines of his own communion to examine the question anew. Four of those divines were, it is said, decidedly opposed to the admission of Anglican orders as valid; four were more or less favourably disposed to them. The report of this commission was then handed over to a committee of cardinals, who pronounced unanimously for the nullity of the orders in question. Thereupon the pope published his bull Apostolicae curae. In it he lays down the infallible nature of the Roman Catholic doctrine of the form "Receive the Holy Ghost," at least from 1552 till the addition of the specific words, "for the office and work of a bishop (or priest) in the church of God," as also on the changes made in the Edardine order "with the manifest intention... of rejecting what the church does." His conclusion is that Anglican orders are "absolutely null and utterly void." Moreover, in a letter to Cardinal Richard, archbishop of Paris, the pope affirms that this his solemn decision is "firm, authoritative and irrevocable."

For Roman Catholics the decision necessarily carries great weight, and it may perhaps have its influence on Anglicans of the school which approximates most closely to Roman belief. It need not affect the opinion of dispassionate students. It is not the judgment of experts. The rejection of Anglican orders in the 16th and 17th centuries was based on a theory about the "tradition of institutions," which has long ceased to be tenable in the face of history, and is abandoned by Romanists themselves. The opinion of a liturgical scholar like Mgr. Louis Duchesne, who was a member of the papal commission on the general question would be interesting in the highest degree. Unfortunately we know nothing of his vote or of the reasons he gave for it, and outside of the Roman pale the 'unanimous decision of a committee of cardinals counts for very little. We may grant the pope's contention that the Edardine church had no belief in priests who offered in sacrifice the body and blood of Christ or in bishops capable of ordaining such priests. We may grant further that the medieval offices have been deliberately altered to exclude this view. But then the liturgy of Serapio, the friend of Athanasius, recently discovered, contains forms for the ordination of priests and bishops which do not say a word about power to sacrifice, much less about power to sacrifice Christ's literal body and blood. The canons of Hippolytus, which are about 150 years older, and indeed all the oldest forms for celebration, absolutely ignore any such power of sacrifice. If they speak of sacrifice at all, it is a sacrifice of the gifts brought by the faithful and distributed in the congregation and among the poor, or again there refers to those spiritual sacrifices which a bishop is to offer "day and night." The Didache and Justin Martyr are no less unsatisfactory from the Roman point of view. In short, the English reformers knew very well that the ordinal and communion office which they drew up could not satisfy the requirements of medieval theology. They appealed not to the school divines, but to Scripture and primitive antiquity. That is the standard by which we are to test their work."

AUTHORITIES.—For holy order in the apostolic and sub-apostolic age the reader may consult R. Rothe, Anfänge der christlichen Kirche (1837); A. Rüsch's Entstehung der althälsischen Kirche (2nd ed.; 1857); J. B. Lightfoot's dissertation on the "Christian Ministry" in his commentary on the Philippians (1868). A new era was opened by E. Hatch's Organization of the Early Christian Church (1880); to this Bishop C. Gore's Church and Ministry (1888) is a reply. The facts are judicially stated and weighed in Bishop J. Wordsworth's Ministry of Grace (1902). Dr. T. M. Lindsay's Church and Ministry in Early Centuries (1902) on the whole agrees with Hatch, but is too eager to find modern Presbyterianism in the early church. A. Harnack's edition of the Didache (1884), his essential truth of the Apostolic Canons (Eng. trans., 1895), the edition of the Canons of Hippolytus by H. Achelis, in Texte und Untersuchungen, vol. vi. (191), the translation of Serapion's Prayer-book (translated by Bishop J. Wordsworth, 1895), are indispensable for serious study of the subject. Joann Morinus, De sacris ordinatibus (1635) and A. C. Chardon, Histoire des sacraments, vol. v. (1745), are rich in material chiefly regarding to the patriarchal and early legal orders. For the controversy on Anglican orders see P. F. Courayer, Validité des ordinations anglaises (1732), and two works in reply by M. Le Quien, Nullité des ordinations anglicanes (1725), Nullité des ordres... Serapion's demonstré de nouveau (1730). In recent times Anglican orders have been defended by A. W. Haddam, Apostolical Succession in the Church of England; F. W. Puller, The Bull Apostolicae Curae and the Edardine Ordinal. They have been attacked by E. E. Courtry, Question of Anglican Ordinations (1873), and by A. W. Hutton, The Anglican Ministry, with a preface by Cardinal J. H. Newman (1879). (W. E. A.*)

ORDER IN COUNCIL, in Great Britain, an order issued by the sovereign on the advice of the privy council, or more usually on the advice of a few selected members thereof. It is the modern equivalent of the medieval ordinance and of the proclamation so frequently used by the Tudor and Stewart sovereigns. It is opposed to the statute because it does not require the sanction of parliament; it is issued by the sovereign by virtue of the royal prerogative. But although theoretically orders in council are thus independent of parliamentary authority, in practice they are only issued on the advice of ministers of the crown, who are, of course, responsible to parliament for their action in the matter. Orders in council were first issued during the 18th century, and their legality has sometimes been called in question, the fear being evidently prevalent that they would be used, like the earlier ordinances and proclamations, to alter the law. Consequently in several cases parliament has subsequently passed acts of indemnity to protect the persons responsible for issuing them, and incidentally to assert its own authority. At the present time the principle seems generally accepted that orders in council may be issued on the strength of the royal prerogative, but they must not seriously alter the law of the land.

The most celebrated instance of the use of orders in council was in 1807 when Great Britain was at war with France. In answer to Napoleon's Berlin decree, the object of which was to destroy the British shipping industry, George III. and his ministers issued orders in council forbidding all vessels under penalty of seizure to trade with ports under the influence of France. Supplementary orders were issued later in the same year, and also in 1808. Orders in council are used to regulate the matters which need immediate attention on the death of one sovereign and the accession of another.

In addition to these and other orders issued by the sovereign by virtue of his prerogative, there is another class of orders in council, viz. those issued by the authority of an act of parliament, many of which provide thus for carrying out their provisions. At the present day orders in council are extensively used by the various administrative departments of the government, who act on the strength of powers conferred upon them by some act of parliament. They are used for regulating the details of local government and matters concerning the navy and the army, while a new bishopric is sometimes founded by an order in council. They are also employed to regulate the affairs of the crown colonies, and the lord-lieutenant of Ireland, the viceroy of India, the governor-general of Canada, and other representatives of the sovereign may issue orders in council under certain conditions.

In times of emergency the use of orders in council is indispensable to the executive. In September 1766, a famine being feared, the export of wheat was forbidden by an order in council, and the Regulation of the Forces Act 1871 empowers the government in a time of emergency to take possession of the railway system of the country by the issue of such an order.
ORDERIC VITALIS (1075-1142), the chronicler, was the son of a French priest, Odeler of Orleans, who had entered the service of Roger Montgomery, earl of Shrewsbury, and had received from his patron a chapel in that city. Orderic was the eldest son of his parents. They were learned men; his father was an English priest, Swarday by name, who kept a school in the church of SS Peter and Paul at Shrewsbury. When eleven years old he was entered as a novice in the Norman monastery of St Evroul en Ouche, which Earl Roger had formerly persecuted but, in his later years, was loading with gifts. The parents paid thirty marks for his son's admission; and he expresses the conviction that they imposed this exile upon him from an earnest desire for his welfare. Odeler's respect for the monastic profession is attested by his own retirement, a few years later, into a religious house which Earl Roger had founded at his persuasion. But the young Orderic felt for some time, as he tells us, like Joseph in a strange land. He did not know a word of French when he reached Normandy; his book, though written many years later, shows that he never lost his English cast of mind or his attachment to the country of his birth. His superiors rechristened him Vitalis (after a member of the legendary Theban legion) because they found a difficulty in pronouncing his baptismal name. But, in the title of his Ecclesiastical History he prefixes the old to the new name and proudly adds the epithet Angligena. His cloistered life was uneventful. He became a deacon in 1095, a priest in 1107. He left his cloister on several occasions, and speaks of having visited Croyland, Worcester, Cambrai (1105) and Cluny (1132). But he turned his attention at an early age to historical records. For many years he appears to have spent his summers in the scriptorium. His superiors (at some time between 1099 and 1122) ordered him to write the history of St Evroul. The work grew under his hands until it became a general history of his own age. St Evroul was a house of wealth and distinction. War-worn knights chose it as a resting-place of their last years. It was constantly entertaining visitors from southern Italy, where it had planted colonies of monks, and from England, where it had extensive possessions. Thus Orderic, though he witnessed no great events, was often well informed about them. In spite of a cumbersome and affected style, he is a vivid narrator; and his character sketches are admirable as summaries of current estimates. His narrative is badly arranged and full of unexpected digressions. But he gives us much invaluable information for which we should search the more methodical chroniclers in vain. He throws a flood of light upon the manners and ideas of his own age; he sometimes comments with surprising shrewdness upon the broader aspects and tendencies of history. His narrative breaks off in the middle of 1141, though he added some finishing touches in 1142. He tells us that he was then old and infirm. Probably he did not long survive the completion of his great work.

The Historia ecclesiastica falls into three sections: (1) Bks. i., ii., which are historically valueless, give the history of Christianity from the birth of Christ. After 865 this becomes a bare catalogue of popes, ending with the name of Innocent I. These books were added, as an afterthought, to the original scheme; they were composed in the years 1126-1141. (2) Bks. iii., iv., v., vi., dealing with St Evroul, the original nucleus of the work. Planned before 1122, they were mainly composed in the years 1123-1131. The fourth and fifth books contain long digressions on the deeds of William the Conqueror. The sixth book, of 1126, is a reprint of a short Latin work of little value, being chiefly derived from two extant sources. William of Jumièges' Historia Normannorum and William of Poitiers' Gesta Guilhelm. For the years 1067-1071 Orderic follows the last portion of the Gesta Guilhelm, and is the more trustworthy in his first important facts. But his notices of political events in this part of his work are far less copious than in (3) Bks. vii.-xiii., where ecclesiastical affairs are relegated to the background. In this section, after sketching the history of France under its various monarchs, and especially under the first truly independent authority. But his notices of political events in this part of his work are far less copious than in the later years of his own times, starting from about 1082. He has much to say concerning the empire, the papacy, the Normans in Italy and Apulia, the First Crusade (for which he follows Fulcher of Chartres and Baudri of Bourgpre). But his chief interest is in the histories of Duke Robert of Normandy, William Rufus and Henry I. He plans his work in the form of annals, up to the defeat and capture of Stephen at Lincoln in 1141.

The Historia ecclesiastica was edited by Duchesne in his Historiae Normannorum scriptores (Paris, 1619). This is the edition cited by Freeman and in many standard works. It is, however, inferior to that of A. le Prévost in five vols. (Soc. de l'histoire de France, Paris, 1838-1855). The fifth volume contains excellent critical studies by M. Leopold Delisle, and is admirably indexed. Migne's edition (Patrologiae cursus completus, Paris, 1890-1914) is a reprint of Duchesne's. There is a French translation (by L. Dubois) in Guizot's Collection des mémoires relatifs à l'histoire de France (Paris, 1852-1872); and one in English by T. Forester in Bohn's Antiquarian Library (4 vols., 1853-1866). In addition to the Historia there exists in the library at Rouen, a manuscript edition of William of Jumièges' Historia Normannorum which Leopold Delisle assigns to Orderic (see this critic's Lettres à M. Jules Laisn (1873).

(From History of England by W. C. D.)

ORDINANCE, or Ordonnance, in architecture, a composition of some particular order or style. It need not be restricted to columnar composition, but applies to any kind of design which is subjected to conventional rules for its arrangement.

ORDINANCE, in medieval England, a form of legislation. The ordinance differed from the statute because it did not require the sanction of parliament, but was issued by the sovereign by virtue of the royal prerogative, although, especially during the reign of Edward I, the king frequently obtained the assent of his barons and earls. His or their ordinances define the ordinance as "a regulation made by the king, by himself or in his council or with the advice of his council, promulgated in letters patent or in charter, and liable to be recalled by the same authority." But after remarking that "these generalisations do not cover all the instances of the use of ordinance," he adds: "The statute is primarily a legislative act, the ordinance is primarily an executive one." Legislation by ordinance was very common during the reigns of Henry III. and Edward I. when laws were issued by the king in council or enacted in parliament indifferently. Both were regarded as equally binding. Soon, however, legislation by ordinance aroused the jealousy of parliament, especially when it was found that acts of parliament were altered and their purpose defeated by this means. Consequently in 1389 the Commons presented a petition to King Richard II. asking that no ordinance should be made contrary to the common law, or the ancient customs of the land, or the statutes ordained by parliament. For this and other reasons this form of legislation fell gradually into disuse, becoming obsolete in the 15th century. The modern equivalent of the ordinance is the order in council.

In 1310, when Edward II. was on the throne and England was in a very disturbed condition, a committee of twenty-one bishops, earls and barons was chosen to make certain ordinances for the better government of the country. These men were called ordainers.

In the 17th century the use of the word ordinance was revived, and was applied to some of the measures passed by the Long Parliament, among them the famous self-denying ordinance of 1645. This form was used probably in conformity with the opinion of Sir Edward Coke, who says in his Fourth Institute "an ordinance in parliament wanteth the threefold consent, and is ordained by one or two of them" (i.e., kings, lords and commons). The ordinances of the Long Parliament did not, of course, obtain the assent of the king. At the present time the word ordinance is used to describe a body of laws enacted by a body less than sovereign. For example, the ordinances of Southern Nigeria are issued by the governor of that colony with the assent of his council.

Before 1780 the kings of France frequently issued ordonnances. These were acts of legislation, and were similar to the ordinances of the English kings in medieval times.

ORDINARY (med. Lat. ordinarius, Fr. ordinaire), in canon law, the name commonly employed to designate a superior ecclesiastic exercising "ordinary" jurisdiction (jurisdictionem ordinariam), i.e., in accordance with the normal organization of the church. It is usually applied to the bishop of a diocese and to those who exercise jurisdiction in his name or by delegation of his functions. Thus, in Germany, the term ordinariat is applied to the whole body of officials, including the bishop, through whom a diocese is administered. In English law, however, the term ordinary is now confined to the bishop and the chancellor
ORDINATE—ORDNANCE 189

of his court. The pope is the ordinarius of the whole Roman Catholic Church, and is sometimes described as ordinarius ordinariorum. Similarly in the Church of England the king is legally the supreme ordinary, as the source of jurisdiction.

The use of the term ordinary is not confined to ecclesiastical jurisdiction. In the civil law the judex ordinarius is a judge who has regular jurisdiction as of course and of common right as opposed to persons extraordinarily appointed. The term survived throughout the middle ages wherever the Roman law gained a foothold. In the Byzantine empire it was applied to any one filling a regular office (e.g. ἱερατος ὁδηγός = consul ordinarius, ἥγεως ὁδηγός = praefectus ordinarius); but it also occasionally implied rank as distinct from office, all those who had the title of clarissimus being sometimes described as ὁδηγὸς. In England the only case of the term being employed in its civil use was that of the office of judge ordinary created by the Divorce Act of 1857, a title which was, however, only in existence for the space of about eighteen years owing to the incorporation of the Divorce Court with the High Court of Justice by the Judicature Act 1875. But in Scotland the ordinary judges of the Inner and Outer Houses are called lords ordinary, the junior lord ordinary of the Outer House acts as lord ordinary of the bills, the second junior as lord ordinary on teneds, the third junior as lord ordinary on Exchequer causes. In the United States the ordinary possesses, in the states where such an officer exists, powers vested in him by the constitution and acts of the legislature identical with those usually vested in the courts of probate. In South Carolina he was a judicial officer, but the office no longer exists, as South Carolina has now a probate court.

In the German universities the Professor ordinarius is the occupant of one of the regular and permanent chairs in any faculty.

ORDINATE, in the Cartesian system of co-ordinates, the distance of a point from the horizontal axis (axis of x) measured parallel to the axis of y. Thus PR is the ordinate of P. The word appears to have been first used by René Descartes, and to be derived from linea ordinata, a term used by Roman surveyors for parallel lines. (See Geometry: Analytical.)

ORDINANCE (a syncopated form of “ordinance” or “ordonnance,” so spelt in this sense since the 17th century), a general term for great guns for military and naval purposes, as opposed to “small arms” and their equipment; hence the term also includes miscellaneous stores under the control of the ordnance department as organized. In England the Master-General of the Ordnance, from Henry VIII.'s time, was head of a board, partly military, partly civil, which managed all affairs concerning the artillery, engineers and matériel of the army; this was abolished in 1855, its duties being distributed. The making of surveys and maps (see Map) was, for instance, handed over eventually (1889) to the Board of Agriculture, though the term “ordnance survey” still shows the origin.

I. HISTORY AND CONSTRUCTION

The efficiency of any weapon depends entirely on two factors: (1) its power to destroy men and material, and (2) the moral effect upon the enemy. Even at the present day the moral effect of gunfire is of great importance, but when guns were first used the noise they made on discharge must have produced a bewildering fear in those without previous experience of them; more especially would this be the case with horses and other animals. Villani wrote of the battle of Cressy that the “English guns made a noise like thunder and caused much loss in men and horses” (Hime, Proc. R. A. Institution, vol. 26). Now, the moral effect may be considered more or less constant, for, as men are educated to the presence of artillery, the range of guns, their accuracy, mobility and on shore their invisibility, so increase that there is always the ever present fear that the stroke will fall without giving any evidence of whence it came.

On the other hand, the development of the gun has always had an upward tendency, which of late years has been very marked; the demand for the increase of energy has kept pace with—or rather in recent times may be said to have caused—improvements in metallurgical science.

The evolution of ordnance may be divided roughly into three epochs. The first includes that period during which stone shot were principally employed; the guns during this period (1313 to 1520) were mostly made of wrought iron, although the art of casting bronze was then well known. This was due to the fact that guns were made of large size to fire heavy stone shot, and, in consequence, bronze guns would be very expensive, besides which wrought iron was the stronger material. The second epoch was that extending from 1520 to 1854, during which cast iron round shot were generally employed. In this epoch, both bronze and cast iron ordnance were used, but the progress achieved was remarkably small. The increase of power actually obtained was due to the use of corn, instead of serpentine, powder, but guns were undoubtedly much better proportioned towards the middle and end of this period than they were at the beginning. The third or present epoch may be said to have commenced in 1854, when elongated projectiles and rifled guns were beginning to be adopted. The rapid progress made during this period is as remarkable as the unproductiveness of the second epoch. Even during recent years the call for greater power has produced results which were believed to be impossible in 1890.

The actual date of the introduction of cannon, and the country in which they first appeared, have been the subject of much antiquarian research; but no definite conclusion has been arrived at. Some writers suppose (see Brackenbury, “Ancient Cannon in Europe” in Proc. Royal Artillery Inst., vol. iv.) that gunpowder was the result of a gradual development from incendiary compounds, such as Greek and sea fire of far earlier times, and that cannon followed in natural sequence. Other writers attribute the invention of cannon to the Chinese or Arabs. In any case, after their introduction into Europe a comparatively rapid progress was made. Early in the 14th century the first guns were small and vase shaped; towards the end they had become of huge dimensions firing heavy stone shot of 300 to 500 lb weight.

The earliest known representation of a gun in England is contained in an illuminated manuscript “De Officis Regum” at Christ Church, Oxford, of the time of Edward II. (1326). This clearly shows a knight in armour firing a short primitive weapon shaped something like a vase and loaded with an incendiary arrow. This type of gun was a muzzle loader with a vent channel at the breech end. There seems to be undoubted evidence that in 1338 there existed breech-loading guns of both iron and brass, provided with one or more moveable chambers to facilitate loading (Proc. R. A. I., vol. iv. p. 291). These firearms were evidently very small, as only 2 lb of gunpowder were provided for firing 48 arrows, or about seven-tenths of an ounce for each charge.

The great Bombarde of Ghent, called “Dulle Griete” (fig. 1) is believed to belong to the end of the century, probably about

![Fig. 1.—Dulle Griete, Ghent.](1382, and, according to the Guide des voyageurs dans la ville de Gand (Voisin) the people of Ghent used it in 1411. This gun,
which weighs about 13 tons, is formed of an inner lining of wrought iron longitudinal bars arranged like the staves of a cask and welded together, surrounded by rings of wrought iron, driven or shrunk on. The chamber portion is of smaller diameter, and some suppose it to be screwed to the muzzle portion.

The length of the gun is 197 in., the diameter of the bore 25 in., and the chamber 10 in. at the front and tapering to 6 in. diameter at the breech end. It fired a granite ball weighing about 700 lb. Two wrought iron guns left by the English in 1423 when they had to raise the siege of Mont St Michel in Normandy belong to about the same period; the larger of these guns has a bore of 19 in. diameter. “Mons Meg” (fig. 2) in Edinburgh Castle is a wrought iron gun of a little later period; it is built up in the same manner of iron bars and external rings. It has a calibre of 20 in. and fired a granite shot weighing 330 lb.

Bronze guns of almost identical dimensions to the “Dulle Griete” were cast a little later (1468) at Constantinople (see Lefroy, Proc. R. A. I., vol. vi.). One of these is now in the Royal Military Repository, Wollwich. It is in two pieces screwed together: the front portion has a calibre of 25 in. and is for the reception of the stone shot, which weighed 672 lb.; and a rear portion, forming the powder chamber, of 10 in. diameter. The whole gun weighs nearly 132 tons.

To give some idea of the power of these guns, the damage done by them to Sir John Duckworth’s squadron in 1807 when the Dardanelles were forced may be instanced. In this engagement six men-of-war were more or less damaged and some 126 men were killed or wounded. The guns were too unwieldy to lay for each round and were consequently placed in a permanent position; they were often kept loaded for months.

The 16th century was remarkable from the fact that the large bombard type was discarded and smaller wrought iron guns were made. This was due to the use of iron projectiles, which enabled a blow to be delivered from a comparatively small gun as destructive as that from the very weighty bombards throwing stone shot.

Bronze guns also now came into great favour. They were first cast in England in 1521 (Henry VIII.), and iron cannon about 1540, foreign founders being introduced for the purpose of teaching the English the art. The “Mary Rose,” which sank off Spithead in 1545, had on board both breech-loading wrought-iron and muzzle-loading bronze guns.

The smaller guns cast at this period were of considerable length, probably on account of the large charges of gunpowder which were fired. The long bronze gun in Dover Castle known as “Queen Elizabeth’s pocket pistol” has a calibre of 4·75 in.; its bore is 23 ft. 1 in. long or 58 calibres, but its total length including the cascable is 24 ft. 6 in. It was cast at Utrecht in 1544 and presented by Charles V. to Henry VIII.

Little or no classification of the various types of guns was attempted during the 15th century. The following century saw some attempt made at uniformity and the division of the several calibres into classes, but it was not until about 1730, when Maritz of Geneva introduced the boring of guns from the solid, that actual uniformity of calibre was attained, as up to this date they were always cast hollow and discrepancies naturally occurred. In France organization was attempted in 1732 by Vallière, but to Gribéauval (t.e.) is due the credit of having simplified artillery and introduced great improvements in the equipment.

It is not possible to compare properly the power of the earlier guns; at first small and feeble, they became later large and unwieldy, but still feeble. The gunpowder called “serpentine” often compounded from separate ingredients on the spot at the time of loading, burnt slowly without strength and naturally varied from round to round. The more fiercely burning granulated or corned powder, introduced into Germany about 1429, and

FIG. 2.—Mons Meg.

Redrawn from Mallet’s Construction of Artillery.

Fig. 3.—Primitive Gun-mounting.

secured thereto by iron straps or ropes. The ponderous weight to be moved and the deficiency of mechanical means prevented these large cannon and their cradles from being readily moved when once placed in position. Laying was of the most primitive kind, and the bombard was packed up in its wood cradle to the required elevation once for all. When it was desired to breach a wall the bombard with its bed would be laid on the ground at about 100 yds. distance, the breech end of the gun or the rear end of the bed abutting against a solid baulk of wood fixed to the ground. “Mons Meg” was originally provided with a wood cradle.

It is by no means certain when wheeled carriages were
introduced. They must have gradually appeared as a means of surmounting the difficulties engendered by the recoil of the piece and of transport of the early guns and their cradles. Andrea Redusio mentions in Chronicon Tarvisinum the use of two wheeled bombard carriages at the siege of Quero by the Venetians in 1376. It does not follow that these weapons were of large dimensions, as the term "bombard" was applied to small guns as well as to the more ponderous types.

The ancient carriages used on land are remarkable from the fact that in general design they contain the main principles which have been included in field carriages up to the present day. Until 1870 the body of all field carriages was made of wood. In an early type the trail portion was made of a solid baulk of timber supported at the front by a hard wood axletree, on the arms of which the wheels were placed (iron axletrees were introduced by Gribbeauval in 1765). The gun resting in its wooden cradle was carried in the bearings on the trail immediately over the axletree (fig. 4), the cradle being provided with an axle or trunnions for the purpose. For giving elevation a wood arc was fixed to the trail towards the rear end, and the breech end could be moved up and down along this arc and fixed at certain positions by a pin passing through both cradle and arc.

About the middle of the 15th century the trunnions were formed with the gun—the wooden cradle therefore became unnecessary and was discarded. The carriage was then formed of two strong cheeks or sides of wood fastened together by four wood transoms. At the front end the cheeks were secured to the wooden axletree, which was strengthened by a bar of iron let into its under side. Trunnion bearings were cut in the upper surface of the cheeks over the axletree, and these were lined with iron, while the trunnions were secured in position by iron cap-squares. Elevation was given by a wedge or "quin" being placed under the breech and supported by a transom or stool bed. For transport the trail end of the carriage was supported on a limber, a pinte on the limber body passing through a hole in the trail. One set of shafts were fixed to the limber, and a single horse was harnessed to them; the remainder of the team were attached in pairs in front. A driver was provided for every two pairs of horses. In Italy oxen were often yoked to the larger guns instead of horses. Tartaglia mentions in his Novæ scientiae (1562) that 28 oxen were required for a gun 15 ft. in length and weighing 13,000 lb.; horses were used for small guns only.

For service on board ship the difficulties of the cramped situation seem to have been surmounted in an ingenious manner. In the "Mary Rose," sunk in the reign of Henry VIII., the brass guns with trunnions were mounted on short wood carriages provided with four small wood wheels called "trucks" and fastened to the gun ports by rope breechings. The iron breech-loading guns were employed in restricted positions where loading at the muzzle would be difficult. They had no trunnions and were mounted in a wood cradle, the under side of which was grooved to enable it to slide on a directing bar.

At the end of the 17th century not much progress had been made. The larger guns were mounted on short wood carriages having two or four "trucks." The guns and carriages recolled along the vessel's deck, and where this endangered the masts or other structures the recoil was hindered by soft substances being laid down in the path of the recoil.

The small guns were mounted in iron Y pieces—the upper arms being provided with bearings for the gun trunnions—and the stalk formed a pivot which rested in a socket in the vessel's side or on a wall, so that the gun could be turned to any quarter.

Similar carriages (fig. 5) existed until the advent of rifled guns, but a few small improvements, such as screw elevating gear in place of the quin, had been approved. Cast iron standing carriages were also, about 1825, used on land for hot climates and situations not much exposed.

The earliest guns were not provided with sights or other means for directing them. This was not important, as the range seldom exceeded 100 yds. As, however, ranges became longer, some means became necessary for giving the correct line and elevation (see also Scourrs). The direction for line was easily obtained by looking over the gun and moving the carriage trail to the right or left as was necessary. For elevation an instrument invented by Tartaglia called a Gunner's Quadrant (sometimes also called a Gunner's Square) was used; this was a graduated quadrant of a circle (fig. 6) connecting a long and short arm forming a right angle; a line with a plummet hung from the angle in such a manner that on the long arm being placed along the bore near the muzzle the plummet hung down against the quadrant and indicated the degrees of elevation given to the piece. The quadrant was divided into 90° and also into 12 parts; it was continued past the short arm for some degrees to enable depression to be given to the gun. The instrument was also used for surveying in obtaining the heights of buildings, and is still much employed for elevating guns in its clinometer form, in which a level takes the place of the plummet.

For short range firing a dispar sight was in use early in the 17th century. A notch was cut on the top of the breech or base ring, and on the muzzle ring a notched fore sight (called the dispar sight) was placed in the same vertical plane as the notch, and of such a height that a line stretched from the top of the breech ring notch to the notch of the foresight was parallel to the axis of the bore. These sights were well enough for close, horizontal fire and so long as the enemy were within what was called "point blank" range; that is the range to the first graze, on a horizontal plane, of the shot when fired from a gun the axis of which is horizontal. As this range depends entirely, other things being equal, on the height of the gun's axis above the horizontal plane, it is not very definite. When, however, the enemy were at a greater distance, elevation had to be given to the gun and, as a quadrant was slow and not easy to use, there was introduced an instrument, called a Gunner's Rule (see The Art of Gunnery, by Nathanael Nye, 1670), which was really a primitive form of tangent sight. This was a flat brass
scale 12 or 14 in. long divided on its flat surface into divisions proportional to the tangents of angles with a base equal to the distance from the notch on the base ring to the dispar part. A slit was made along the rule, and a thread with a bead on it was mounted on a slider so that it could be moved in the slit to any required graduation. By sighting along the bead to the dispar the gun could be laid on any object. Later still, the requisite elevation was obtained by cutting a series of notches on the side of the base ring and one on the muzzle ring. These were called "Quarter Sights" and allowed of elevations up to 5°; the lowest notch with the one on the muzzle swell gave a line parallel to the axis of the bore but above it so as to clear the cap-squares of the trunnions. This system was also used in bronze field guns and in all cast-iron guns up to the 32-pdr. Difficulties in laying occurred unless the direction was obtained by looking over the top or dispar sight and the elevation then given by the quarter sights. This was the system of sighting in use during the great naval actions of the end of the 18th century and the beginning of the 19th century. A pointed dispar sight was often used, and for naval purposes it was fixed on the reinforce near the trunnion as the recoil of the gun through the port would destroy it if fixed on the muzzle swell.

The double sighting operation was rendered unnecessary by the use of "tangent scales" introduced by Gribeauval. Similar scales were soon adopted in the English land service artillery, but they were not fully adopted in the English navy until about 1854 (see Naval Gunnery, by Sir Howard Douglas, p. 390), although in the United States navy a system of sighting, which enabled the guns to be laid at any degree of elevation, had been applied as early as 1812. These tangent scales were of brass fitting into sockets on the breech end of the gun; they were used in conjunction with the dispar fore sight and gave elevation up to 4° or 5° over the top of the gun. For greater elevation a wooden tangent scale was provided which gave elevation up to 8° or 10°.

In the British navy, before tangent sights were used, the plan often adopted for rapidly laying the guns was by sighting, with the notch on the breech ring and the dispar sight, on some part of the masts of the enemy's ship at a height corresponding to the range.

With sailing ships about the middle of the 19th century the angle of heel of the vessel when it was sailing on a wind was ascertained from the ship's pendulum, and the lee guns elevated or the weather guns depressed to compensate by means of a graduated wooden stave called a "heel scale" of which one end was placed on the deck or last step of the carriage whilst the upper end read in connection with a scale of degrees engraved on the flat end of the casable.

Subsequently the term "tangent sight" was given to the "tangent scales," and they were fitted into holes made in the body of the gun—the foresight usually being fitted to a hole in the gun near the trunnions. Two pairs of sights—one at each side—were generally arranged for, and in rioted guns the holes for the tangent sight bars were inclined to compensate for the drift of the projectile. As the drift angle varies with the muzzle velocity, the tangent sights of howitzers were set vertically, so that for the various charges used the deflection to the specimen for drift had to be given on the head of the sight bar. Modern forms of sights are described and illustrated in the article SIGHTS.

Breech-loading ordnance dates from about the end of the 14th century, or soon after the introduction of cannon into England (Brackenbury, Proc. R.A.I. v. 32). The gun body, in some cases, was fixed to a wood cradle by iron straps and the breech portion kept in position between the muzzle portion and a vertical block of wood fixed to the end of the cradle, by a wedge. Accidents must have been common, and improvements were made by dropping the breech or chamber of the weapon into a receptacle, solidly forged on or fastened by lugs to the rear end of the gun (fig. 7). This system was used for small guns only, such as wall pieces, &c., which could not be easily loaded at the muzzle owing to the position in which they were placed, and in order to obtain rapidity each gun was furnished with several chambers.

Guns of this nature, called Petriere's a Braza, were used in particular positions even at the end of the 17th century. Moretall states that they carried a stone ball of from 2 lb to 14 lb, which was placed in the bore of the gun and kept in position by wads. The chambers, resembling an ordinary tankard in shape, had a spigot formed on their front end which entered into a corresponding recess at the rear end of the bore and so formed a rude joint. Each chamber was nearly filled with powder and the mouth closed by a wood stopper driven in; it was then inserted into the breech of the gun and secured by a wedge. Even with feeble gunpowder this means of securing the chamber does not commend itself, but as powder improved there was a greater probability of the breech end of the gun giving way; besides which the escape of the powder gas from the imperfect joint between the chamber and gun must have caused great inconvenience. To these causes must be attributed the general disuse of the breech-loading system during the 18th and first half of the 19th centuries.

Robins mentions (Tracts of Gunnery, p. 337) that experimental breech-loading rifled pieces had been tried in 1745 in England to surmount the difficulty of loading from the muzzle. In these there was an opening made in the side of the breech which, after the loading had been completed, was closed by a screw. The breech arrangement (fig. 8) of the rifled gun introduced by Major Cavalli, a Sardinian officer, in 1845, was far superior to anything tried previously. After the projectile and charge had been loaded into the gun through the breech, a cast iron cylindrical plug, cupped on the front face, was introduced into the chamber; a copper ring was placed against its rear face; finally a strong iron wedge was passed through the body of the gun horizontally just in rear of the plug, and prevented it being blown out of the gun. In England the breech of one of the experimental guns was blown off after only a few rounds had been fired. In Wahrendorf's gun, invented in 1846, the breech arrangement (fig. 9) was very similar in principle to the Cavalli gun. In addition to the breech plug and horizontal wedge there was an iron door, hinged to the breech face of the gun, which carried a rod attached to the rear of the breech plug. The horizontal wedge had a slot cut from its right side to the centre, so that it might freely pass this rod. After loading,
HISTORY AND CONSTRUCTION

ORDNANCE

Up to about 1850 the dimensions of cannon had been proportioned by means of empirical rules, as the real principles underlying the construction of ordnance had been little understood. It was known of course that a gun was subjected to two fundamental stresses—a circumferential tension tending to split the gun open longitudinally, and a longitudinal tension tending to pull the gun apart lengthwise; the longitudinal strength of a gun is usually greatly in excess of any requirements. It is easy to demonstrate that any so-called homogenous gun, i.e. a gun made of solid material and not built up, soon reaches a limit of thickness beyond which additional thickness is practically useless in giving strength to resist circumferential stress. This is due to the fact that the stress on the metal near the bore is far higher than that on the outer portion and soon reaches its maximum resistance which additional thickness of metal does not materially increase. The gun can, however, be arranged to withstand a considerably higher working pressure by building it up on the principle of initial tensions. The inner layers of the metal are thereby compressed so that the gas pressure has first to reverse this compression and then to extend the metal. The gun barrel supported by the contraction of the outer hoops will then be able to endure a gas pressure which can be expressed as being proportional to the initial compression plus the extension, whereas in the old type solid gun it was proportional to the extension only. The first to employ successfully this important principle for all parts of a gun was Lord Armstrong (q.v.), who in 1855-1856 produced a breech-loading field gun with a steel barrel strengthened by wrought iron hoops. In this system (fig. 11) wrought iron coils were shrunk over one another so that the inner tube, or barrel, was placed in a state of compression and the outer portions in a state of tension—the parts so proportioned that each performs its maximum duty in resisting the pressure from within. Further, by forming the outer parts of wrought iron bar coiled round a mandril and then welding the coil into a solid hoop, the fibre of the iron was arranged circumferentially and was thus in the best position to resist this stress. These outer coils were shrunk over a hollow breech-piece of forged iron, having the fibre running lengthwise to resist the longitudinal stress. The several cylinders were shrunk over the steel inner tube or barrel. To obtain the necessary compression the exterior diameter of the inner portion is turned in a lathe slightly greater than the interior diameter of the outer coil. The outer coil is heated and expands; it is then slipped over the inner portion and contracts on cooling. If the strength of the two parts has been properly adjusted the outer will remain in a state of tension and the inner in a state of compression.

Every nation has adopted this fundamental principle which governs all systems of modern gun construction. The winding, at a high tension, of thin wire or ribbon on the barrel or on one of the outer coils may be considered as having an exactly similar effect to the shrinking of thin hoops over one another. The American, Dr Woodbridge, claims to have originated the system of strengthening guns by wire in 1850; Brunel, the great railway engineer, also had similar plans; to Longridge, however, belongs the credit of pointing out the proper mode of winding on the wire with initial tension so adjusted as to make the firing tension (i.e. the tension which exists when the gun is fired) of the wire uniform for the maximum proof powder pressure. Great
success attended the early introduction of the coil system. Large numbers (about 3,000) of breech-loading Armstrong guns from 2.5 in. to 7 in. calibre were manufactured for England alone; most of these had barrels of coiled iron, but solid forged iron barrels were also employed and a few were of steel. This manufacture continued until 1867, when M.L. guns built up on the coil system (fig. 12) with the French form of rifling were adopted; but as the knowledge of the proper treatment and the quality of the steel had improved, steel barrels bored from a solid steel forging were mostly used; the exterior layers were still iron hoops with the fibre of the metal disposed as in the original type. In order to cheapen manufacture the coils were thickened by Mr Fraser of Woolwich Arsenal, so that a few thick coils were used instead of a number of thin ones (fig. 13).

In the Fraser system an attempt was made to obtain rigidity of construction and additional longitudinal strength by interlocking the various coils from breech to muzzle; this feature still exists in all designs adopted by the English government, but foreign designers do not favour it altogether, and many of their guns of the latest type have a number of short independent hoops shrunk on, especially over the chase. Their view is that movements—such as stretching of the inner parts—are bound to take place under the huge forces acting upon the tubes, and that it is better to allow freedom for these to take place naturally rather than to make any attempt to retard them. On the other hand it cannot be denied that the rigid construction is conducive to strength and durability, but it is essential that massive tubes of the highest quality of steel should be employed.

The actual building up of a gun entails operations which are exactly similar, whether it be of the M.L. or B.L. system; and the hardening treatment of the steel is also the same—the coiled iron hoops when welded, of course, received no such treatment.

Fig. 12.—M.L. Gun Construction.

Fig. 13.—M.L. Gun Construction (Fraser).

Fig. 14 shows the various stages of building up a B.L. gun and illustrates at the same time the principle of the interlocking system.

The steel barrels of the M.L. guns were forged solid; the material was then tested so as to determine the most suitable temperature at which the oil hardening treatment should be carried out after the barrel had been bored. The bored barrel was simply heated to the required temperature and plunged vertically into a tank of oil. The subsequent annealing process was not introduced until some years after; it is therefore not to be wondered at that steel proved untrustworthy and so was used with reluctance.

Since 1880 the steel industry has made so much progress that this material is now regarded as the metal most to be relied on. The long high-power guns, however, require to be worked at a greater chamber pressure than the older B.L. guns, with which 15 tons or 16 tons per square inch was considered the maximum. With the designs now produced 18.5 tons to 20 tons per square inch working pressure in the chamber is the general rule.

A stronger material than ordinary carbon gun steel was consequently demanded from the steel-makers, in order to keep the weights of the heavier types of guns within reasonable limits. The demand was met by the introduction of a gun having about 4% of nickel in addition to about 0.4% of carbon. This alloy gives great toughness and endurance under a suitable oil hardening and annealing process, the yielding stress being about 26 tons to 28 tons and the breaking stress from 45 tons to 55 tons per square inch, with an elongation of 16%. The tests for ordinary carbon gun steel are: yield not less than 21 tons, breaking stress between 34 tons and 44 tons per square inch, and elongation 17.5%.

The toughness of nickel steel forgings renders them much more difficult to machine, but the advantages have so far been great that practically all barrels and hoops (except jackets) of modern guns are now made of this material.

The gun steel, whether of the carbon or nickel quality, used in England and most foreign countries, is prepared by the open hearth method in a regenerative gas furnace of the Martin type (see iron and steel). The steel is run from the furnace into a large ladle, previously heated by gas, and from this it is allowed to run into a cast iron ingot mould of from 10 to 12 ft. high and 2 ft. or more in diameter. With very large ingots two furnaces may be the centre; from two to four moulds may be the centre. The external shape of these ingots varies in different steel works, but they are so arranged that, as the ingot slowly cools, the contraction of the metal shall not set up dangerous internal stresses. The top of the ingot is generally porous, and consequently, after cooling, it is usual for about one-third of the length of the ingot to be cut from the top and remelted; a small part of the bottom is also often discarded. The centre of the larger ingots is also inclined to be unsound, and the pressure amounts to, for ordinary purposes, from 1000 tons to 5000 tons, while for the manufacture of armour plates it may amount to as much as 10,000 or 12,000 tons.

For forgings of 6-in. internal diameter and upwards, the bored out ingot, just mentioned, is forged hollow on a tubular mandrel, kept cool by water running through it; under this treatment forging work can be performed before the metal has cooled down too much. Generally one end of the ingot is forged down to the proper size; it is then reheated and the other end similarly treated. The forging of the steel and the subsequent operations have a very marked influence on the structure of the metal, as will be seen from the micro-photographs shown in the article ALLOYS, where (a) and (b) show the structure of the cast steel of the actual ingot; from this it will be noticed that the crystals are very large and prominent, but, as the metal passes through the various operations, these crystals become smaller and less pronounced. Thus (c) and (d) show the metal after forging; (e) shows the pearlite structure with a magnification of 1000 diameters, which disappears on the steel being oil hardened, and (f) shows the oil hardened and annealed crystals. At the Bofors Works in Sweden, gun barrels up to 24 cm. (9.5 in.) calibre have been formed of an unforged cast steel tube; this is a very expensive gun, is not followed by other nations.

After the forging is completed, it is annealed by reheating and cooling slowly, and test pieces are cut from each end tangentially.
Fig. 15.—FORGING PROCESS.
Fig. 18.—SHRINKING-ON PROCESS.
to the circumference of the bore; these are tested to ascertain the quality of the steel in the soft state.

It is found that the quality of the steel is greatly improved by forging, so long as this is not carried so far as to set up a laminar structure in the metal, which is thereby rendered less suitable for gun construction—being weaker across the laminas than in the other directions. It is then termed over-forged.

If the tests are satisfactory the forging is rough-turned and bored, then reheated to a temperature of about 1600 °F, and hardened by plunging it into a vertical tank of rape oil. This process is a somewhat critical one and great care is observed in uniformly heating, to the required temperature, the whole of the forging in a furnace in close proximity to the oil tank into which it is plunged and completely submerged as rapidly as possible. In some cases the oil in the tank is circulated by pumping, so that uniformity of cooling is ensured; and, in addition, the oil tank is surrounded by a water jacket which also helps to keep it at a uniform heat. The forging is subsequently again heated to about 1200 °F, and allowed to cool slowly by being placed in warm sand, &c. This last operation is termed annealing, and is intended to dissipate any internal stress which may have been induced in the forging by any of the previous processes, especially that of oil-hardening. After this annealing process a second set of test pieces, two for tensile and two for bending test, are cut from each end of the forging in the positions above mentioned; for guns of less than 3-in. calibre only half this number of test pieces is taken, and with hoops of less than 48 in. in length the test pieces are taken only from the end which formed the upper part of the cast ingot.

In all cases of annealed steel the test pieces of 2 in. length and 0.533 in. diameter must give the stipulated results according to the character of the steel. For breach screws the steel is made of a harder quality, as it has to resist a crushing stress; these are the tests required in England, but they differ in different countries; for instance in France a harder class of carbon steel is employed for hoops, in which the tensile strength must not be less than 44.5 tons, nor the elastic limit less than 28.5 tons per square inch, neither must the elongation fall below 12%.

Assuming that the tests of the annealed forging are satisfactory, the forging, which we will suppose to be a barrel, is tested for straightness and if necessary rectified. It is then rough-turned in the lathe (fig. 16) "to break the skin" (as it is termed technically) and so prevent warping during the subsequent operations. It is then bored out to nearly the finished dimension and afterwards fine turned for the part to enter the barrel. The other portions of the gun are in progress, and as it is far easier to turn down the outside of a tube than to bore out the interior of the superimposed one to the exact measurements required to allow for shrinkage, the interior of the jacket and other hoops are bored out after the breech and the exterior of the internal tubes or of the barrel is fine turned. The process of boring is illustrated in fig. 17. The barrel or hoop A, to be bored, is passed through the revolving headstock B and firmly held by jaws C, the other end being supported on rollers D. A head E, mounted on the end of a boring bar F, is driven gradually through the barrel, as it revolves, by the leading screw K actuated by the gear G. The boring head is provided with two or more cutting tools, and also with a number of brass pins or pieces of hard wood to act as guides, in order to keep the boring head central and to prevent warping. The revolving headstock B is driven by a belt and suitable gearing.

With wire guns the procedure is somewhat different. The wire is wound on to its tube, which has been previously fine turned; the exterior diameter of the wire is then carefully measured and the interior of the covering tube or hoop finished to suit. The covering hoop is allowed usually only a small shrinkage, or sometimes none, as it is simply intended as a protection to the wire and to give longitudinal strength; but in order to place it over the wire it must be heated and thus some little contraction always does take place on cooling. The best to which these hoops are brought for shrinking never exceeds that used in annealing, otherwise the modifying effects of this process would be interfered with.

In the earliest modern type B.L. guns, the breech screw engaged directly with a screw thread cut in the barrel, which thus had to resist a large portion, if not all, of the longitudinal stress. This was also the system first adopted in France, but there are certain objections to it, the principal being that the barrel must be made of large diameter to meet the longitudinal stress, and this in consequence reduces the circumferential strength of the gun. Again, the diameter of the screw is always considerably larger than the breech opening, and so an abrupt change of section takes place, which it always best to avoid in structures liable to sudden shocks. The thick barrel, however, need not be so thickly bored as before, and does not materially lengthen with firing; thin barrels on the other hand are gradually extended by the drawing out action of the shot as it is forced through the gun. In some large guns with excessively thin barrels this action was so pronounced as to entail considerable inconvenience. In the English system the breech screw is engaged either in the breech piece, i.e. the hoop which is shrunk on over the breech end of the barrel, or in a special bush screwed into the breech piece. This latter method suits the latest system of construction in which the breech piece is put on the barrel from the muzzle, while with the earlier type it was put on from the breech end.

With the earlier modern guns short hoops were used whenever possible, as, for instance, over the chase, principally because the steel in short lengths was less likely to contain flaws, but as the metallurgical processes of steel making developed the necessity for this disappeared, and the hoops became gradually longer. This has however, increased correspondingly the difficulties in boring and turning, and to a measure greater building up the gun. In this operation the greatest care has to be taken, or warping will occur during heating. The tubes are heated in a vertical cylindrical furnace, gas jets playing both on the exterior and interior of the tube. When sufficiently hot, known by the diameter of the tube expanding to equal previously prepared gauges, the tube is raised out of the furnace and dropped vertically over the barrel or other portion of the gun (fig. 18, Plate II). In cooling it shrinks longitudinally as well as circumferentially, and in order to allow gaps between adjoined tubes the tube is, after being placed in position, cooled at one end by a ring of water jets to make it gripe, while the other portions are kept hot by rings of burning gas flames, which are successively extinguished to allow the hoop to shorten gradually and thus prevent internal longitudinal stress. A stream of water is also directed along the interior of the gun during the building up process, in order to ensure the hoop cooling from the interior. After the building up has been completed, the barrel is fine-bored, then chambered and rifled. The breech is then screwed either for the bush or breech screw and the breech mechanism fitted to the gun.

In order to obtain additional longitudinal strength the outer tubes are so arranged that each hooks on to its neighbour far from breech. Thus, the chase hoop hooks on to the barrel by a step, and the succeeding hoops hook on to each other until the jacket is reached which is then secured to the breech piece by a strong screwed ring. In all the latest patterns of English guns there is a single chase hoop covering the forward portion of the
gun and a jacket covering the breech portion, an arrangement which simplifies the design but increases the difficulties of manufacture.

Wire guns are now made of almost all calibres, ranging from 3 in. to 12 in. Many authorities objected to guns of less calibre than necessary, in order to prevent the fatigue of the material, to make the barrel comparatively thick, or, better still, to have an outer barrel superimposed on the inner one. This latter arrangement is now used in all guns of 4 in. calibre and upwards. It is not so important with smaller guns as the barrel is always relatively thick, and therefore meets the conditions.

With many modern guns the interior of the outer barrel, termed the "A" tube, is taper bored, the larger end being towards the breech; and the exterior of the inner barrel or liner, called the "inner A tube," is made tapered to correspond. The latter is, after careful fitting, inserted in the outer barrel while both are cold, and forced into position by hydraulic pressure or other mechanical means.

The details of the machines for winding on the wire (see fig. 20) differ somewhat in different works, but all are arranged so that any desired tension can be given to the wire as it is being wound on to the gun. The wire is manufactured in much the same way as ordinary wire. A red-hot bar of steel, gradually rolled down between rollers to a section about double that which it is finally intended to have, is annealed and carefully pickled in an acid bath to detach any scale. It is then wound on a drum, ready for the next process, which consists in drawing it through graduated holes made in a hardened steel draw-plate, the wire being often annealed and pickled during this process. The drawplate holes vary in size from slightly smaller than the rolled bar section to the finished size of the wire, and, as a rule, the sharp corners of the wire are only given by the last draw. It is found that considerable wear takes place in the holes of the draw-plate, and a new plate may be required for each hank of 500 or 600 yds. of wire. Great importance is attached to the absence of scale from the wire when it is being drawn, and, after pickling, the rolled bar and wire are treated with lime or some similar substance to facilitate the drawing. The tests for the finished wire are as follows: it has to stand a tensile stress of from 90 to 110 tons per square inch of section, and a test for ductility in which a short length of wire is twisted a considerable number of times in one direction, then unwound and re-twisted in the opposite direction, without showing signs of fracture. It will be seen that the wire is extremely strong and the moderate stress of from 35 to 50 tons per square inch, which at most it is called upon to withstand in a gun, is far less than what it could endure with perfect safety.

The wire after being manufactured is made up into hanks for storage purposes; but when required for gun construction it is thoroughly cleaned and wound on a drum R about 3 ft. 6 in. in diameter, which is placed in one portion of the machine in connexion with a powerful band friction brake M. The wire is then led to the gun A placed between centres or on rollers B.B, parallel to the axis of the wire drum. By rotating the gun the wire is drawn off from the drum against the resistance of the band brake, which is so designed that, by adjusting the weight S suspended from the brake strap, any desired resistance can be given in order to produce the necessary tension in the wire as it is being wound on the gun. The stress on
the wire is indicated on a dial, and the headstock, containing the drum of wire, is capable of being moved along the bed G by a leading screw H, driven by a belt through variable speed cones I; the belt is moved along the cones by forks J, traversed by screws K, which in their turn are actuated by chain belts from the hand wheel L. The traversing speed is regulated to suit the speed of winding by moving the belt along the speed cones.

The wire is rectangular in section, 0.25 in. wide and 0.06 in. thick, and after it has been wound on to the gun it presents a very even surface which requires little further preparation. The diameter over the wire is gauged and the jacket or other covering hoop is carefully bored equal to this, if no shrinkage is to be allowed; or the dimension is diminished in accordance with the amount of shrinkage to be arranged for.

The gun is built up, after wiring, in the same manner as a gun without wire, the jacket or other hoop being heated in the vertical gas furnace and when hot enough dropped into place over the wire, cooled by the ring of water jets at the end first required to grip and keep the other, exactly as before described.

The machine arranged for rifling modern guns is very similar to that employed for the old muzzle-loaders; it is a special tool used in gun construction only (fig. 21), and in reality copying machine. A steel or cast-iron bar J which forms the copy of the developed rifling curve is first made. The copying bar—which is straight if the rifling is to be uniform but curved if it is to be increasing—is fixed, inclined at the proper angle, to standards K on the machine. The cutting tool is carried at one end C of a strong hollow cylindrical rifling bar B, the other end of which is fixed to a saddle M. This is moved along the bed of the machine by a long screw N, and the rifling bar is consequently either pushed into the gun or withdrawn by the motion of the saddle along the machine. During this motion it is made to rotate slowly by being connected to the copying bar by suitable gearing L. It will thus be seen that the cutting tool will cut a spiral groove along the bore of the gun in strict conformity with the copy. In most English machines the cutting tool cuts only as the rifling bar is drawn out of the gun; during the reverse motion the cutter F is withdrawn out of action by means of a wedge arrangement actuated by a rod passing through the centre of the rifling bar, which also pushes forward the cutter at the proper time for cutting. One, two or more grooves may be cut at one time, the full depth being attained by slowly feeding the tool after each stroke. After each set of grooves is cut the rifling bar or the gun is rotated so as to bring the cutters to a new position. In some foreign machines the cut is taken as the rifling bar is pushed into the gun.

Rifling is the term given to the numerous shallow grooves cut spirally along the bore of a gun; the rib between two grooves is called the "land." Rifling has been known for many years; it was supposed to increase the range, and no doubt did so, owing to the fact that the bullet having to be forced into the gun during the loading operation became a mechanical fit and prevented to a great extent the loss of gas by windage which occurred with ordinary weapons. Kotter (1520) and Danner (1552), both of Nuremberg, are respectively credited as being the first to rifle gun barrels; and there is at the Rotunda, Woolwich, a muzzle-loading barrel dated 1547 rifled with six fine grooves. At this early period, rifling was applied only to small arms, usually for sporting purposes. The disadvantage of having, during loading, to force a soft lead (or lead-covered) ball down a bore of smaller diameter prevented its general employment for military use. In 1661 Prussia experimented with a gun rifled in thirteen shallow grooves, and in 1666 the elliptical bore—similar to the Lancaster—had been tried in Germany. In 1745 Robin was experimenting with rifled guns and elongated shot in England. During the Peninsular War about 1800, the only regiment (the "Rifle Brigade," formerly called the 95th) equipped with rifled arms, found considerable difficulty in loading them with the old spherical lead bullet, from the muzzle. In 1835 Russia made a large number of experiments with a rifled gun invented by Montigny, a Belgian; this was not a success, but in England the guns invented by Major Cavalli, in 1845, and by Baron Wahrendorff in 1846, obtained some measure of favour. Both these guns were breech-loaders. The Cavalli gun had a bore of 6.5 in. diameter; it was rifled in two grooves having a uniform twist of 1 in 25 calibres, and the elongated projectile had two ribs cast with it to fit the grooves, but no means were taken to prevent windage. The Wahrendorff gun had an enlarged chamber and the bore of 6.37 in. diameter was rifled in 2 grooves; the projectile had ribs similar to that for the Cavalli gun; but Wahrendorff had also tried lead-coated projectiles, the coating being attached by grooves undercut in the outside of the shell. In 1854 Lancaster submitted his plan of rifling; in this (fig. 22) the bore was made of an oval section which twisted round the axis of the gun from the breech to the muzzle; a projectile having an oval section was fired. Several old cast-iron guns bored on this system burst in the Crimean War from the projectile wedging in the gun. In 1855 Armstrong experimented with a breech-loading rifled gun, firing a lead-coated projectile. The rifling consisted

**FIG. 21.—Rifling Machine.**

![Diagram of Rifling Machine](image)

of a large number of shallow grooves having a uniform twist of 1 in 38 calibres. When the gun was fired the lead-coated projectile, which was slightly larger in diameter than the bore of the gun, was forced into the rifling and so gave rotation to the elongated projectile. Whitworth in 1857 brought out his hexagonal bore method of rifling and a projectile which was a good mechanical fit to the bore. Good results were obtained,
but although this system had certain advantages it did not fulfill all requirements.

In 1863, England re-opened the whole question, and after exhaustive trials of various inventions decided on the adoption of the muzzle-loading type for all guns, with the French system of rifling. This system was invented in 1842 by Colonel Tretille de Beaulieu and consisted of a few wide and deep grooves which gave rotation to a studded projectile. At the first trials two grooves only were tried, but the number was afterwards increased to three or more, as it was found that two grooves only would not correctly centre the projectile. The adoption of the muzzle-loading system with studded shot was a distinctly retrograde step, as a considerable amount of clearance was necessary between the bore and projectile for the purposes of loading, and this resulted in the barrel being seriously eroded by the rush of gas over the shot, and also led to a considerable loss of energy. In the Wahrendorff and Armstrong systems however the lead-coated projectiles entirely prevented windage, besides which the projectile was perfectly centred and a high degree of accuracy was obtained.

Shunt rifling was a brief attempt to make loading by the muzzle easy without forfeiting the centring principle; in this the rifling varied in width and in depth, at different portions of the bore in such a manner that, during loading, the studs on the projectile could move freely in the bore. When the gun was fired the studs of the projectile were forced to travel in the shallow part of the rifling, thus gripping and centring the projectile as it left the muzzle.

With uniform rifling on the French system, the few studs—generally two per groove—had to bear so high a pressure to produce rotation that they sometimes gave way. This subject was investigated by Captain (Sir Andrew) Noble, who showed that by making the rifling an increasing twist, commencing with no twist and gradually increasing until the necessary pitch was obtained, the maximum pressure due to rotation was much reduced. Increasing rifling was consequently adopted, with beneficial results.

In order to prevent the heavy erosion due to windage, a gas check was adopted which was attached to the base end of the studded projectiles. In some guns the number of grooves of the rifling was sufficiently great to admit of rotation being insured by means of the gas check alone; in these guns studded projectiles were not employed, but the gas check, called "automatic," to distinguish it from that fitted to studded projectiles was usually indented around its circumference to correspond with the rifling of the gun. It was found that the studdless projectile had considerably greater range and accuracy than the studded projectile, with the additional advantage that the shell was not weakened by the stud holes.

The introduction of the plain copper driving band for rotating projectiles with breech-loading guns included a return to the polygon system with shallow grooves; this still exists, but the continuous demand for greater power has had the effect of increasing the number of grooves from that at first considered necessary, in order to keep the rotating pressure on the driving band within practical limits.

Many ingenious devices for giving rotation and preventing the escape of gas past the projectile were tried in the early days of modern rifling. Experiments of this nature still continue to be made with a view to improving the shooting and to prevent the erosion of the bore of the gun. Briefly considered, without going into any detail of the numerous plans, all rotating devices fitted to projectiles can be divided into three classes—the "centring," the "compressing" and the "expansion" systems. The two last named almost invariably include the "centring" type. Studded (fig. 23) and Whitworth (fig. 24) hexagonal projectiles, which can freely slide in the bore, come under the first system.

In the compression class the coating or rings on the projectile are larger in diameter than the bore and when fired the coating (or rings) is squeezed or engraved by the rifling to fit the bore—the projectile is consequently also centred. The old-fashioned lead-coated shell (fig. 25), and the modern system of plain copper driving bands (fig. 26), come under this class. Most variety exists in the expansion type, where the pressure of the powder gas acts on the base of the projectile on the driving ring and compresses a lead, copper or asbestos ring into the rifling grooves. One of the earliest was the Hotchkiss (1862) shell (fig. 27), in which a separate base end B was driven forward by the gas pressure and squeezed out the lead ring L into the rifling. The automatic gas check (fig. 28), and the gas check driving band (fig. 29), belong to this system; in the last the lip L is expanded into the rifling groove. In fig. 30 a copper driving band is associated with an asbestos packing A, contained in a canvas bag or copper casing made in the form of a ring on the principle of the de Bange obturator; but the results of this have not been entirely satisfactory.

It will be seen that with breech-loading guns the projectile is better centred, and the copper driving band forms a definite stop for the projectile; and, in consequence, the capacity of the gun chamber is practically constant. In addition, the use of a copper driving band ensures a uniform resistance while this is being engraved and the projectile forced through the gun, and also prevents the escape of gas. These elements have a very great influence on the accuracy of the shooting, and fully account for the vastly superior results obtained from breech-loading ordnance when compared with the muzzle-loading type. Driving bands of other materials such as cupro-nickel and ferro-nickel have also been tried.

Many authorities believe that the best results are obtained when the projectile is fitted with two bands, one near the head and the other near the base, and no doubt it is better centred when so arranged, but such shot can only be fired from guns rifled with a uniform twist, and it must also not be forgotten that the groove formed for the front band in the head of the projectile necessarily weakens that part of the projectile which should be strongest.

Projectiles with a driving band at the base only can be fired from guns rifled either uniformly or with increasing twist.

The introduction of cordite (q.v.) about 1890 again brought into special prominence the question of rifling. The erosion caused by this explosive soon obliterated the rifling for some 4 or 5 calibres at the breech end. The driving band of the shell consequently started with indifferent engraving, and with the increasing twist, then in general use, it was feared that the wear would quickly render the gun useless. To remedy this the late Commander Younghusband, R.N., proposed straight rifling, which was adopted in 1895, for that portion of the rifling mostly affected by the erosion, with a gradual increase of the twist thence to the required pitch at the muzzle. Thus, any erosion of the straight part of the rifling would not affect that portion giving rotation, and it was argued that the gun would remain efficient for a longer period. The defect in this system is that when the projectile arrives at the end of the straight rifling it has a considerable forward velocity and no rotation. Rotation is then imparted by the increasing twist of rifling, and the
resulting pressure on the engraved ribs of the driving band rises suddenly to a maximum which, in high velocity guns, the driving band is unable to resist. For this reason the straight portion at the commencement of the rifling has been discarded, and with high powder guns firing a slow burning propellant uniform rifling has again found favour.

It is evident that in order that a projectile may have a definite amount of spin as it leaves the gun a determinate amount of work must be imparted to rotate it during its passage along the rifled portion of the bore. Put briefly, this work is the sum of the products of the pressure losses between the engraved grooves, the lands of the rifling in the gun multiplied by the length of the rifling over which this pressure acts. Sir Andrew Noble has proved theoretically and experimentally (see Phil. Mag., 1863 and 1873; also use of the valve) that this work is not so detrimental to the propelling pressure of the powder gas on the base of the projectile and on the curve of the rifling. If this curve was so proportioned as to make the rotating pressure approximately constant along the bore, the result was an increasing or progressive curve parakting of the nature of a parabola, in which case it was usual to make the last two or three calibres of rifling at the muzzle of uniform twist for the purpose of steadying the projectile and aiding accuracy.

In uniform rifling the curve is a straight line and the rotating pressure is consequently proportional to the propelling gas pressure. The pressure for rotation with uniform rifling therefore rises to a maximum with the propelling pressure and falls as it becomes less towards the muzzle.

With increasing rifling, owing to the angle of twist continually changing as the projectile travels along the bore, the ribs originally engraved by the rifling on the driving band are forced to change direction correspondingly, and this occurs by the surface of the rib revolving along the bore. They are therefore weakened considerably, and it is found that with high velocities the engraved part of the band often entirely disappears through this progressive action.

It will thus be seen that although an increasing twist of rifling may be used to give uniform pressure, it is in the band and if wear takes place, the engraved rib becomes weaker to resist shearing as the shot advances, and the rate of wear also increases owing to the increase of heat by friction. With the very narrow driving bands used for very large guns it is therefore not so detrimental.

With the long modern guns and the high muzzle velocities required, the propelling gas pressures along the bore rise comparatively slowly to a maximum and gradually fall until the muzzle is reached. The pressure of the gas at the muzzle of the barrel is now considerably higher than with the older patterns of B.L. guns.

For modern conditions, in order to obtain an increasing curve giving an approximately constant driving pressure between the rifling and driving band, this pressure must be comparatively high. The maximum rotating pressure, with uniform rifling, is certainly somewhat higher, but not to a very great extent, and as it occurs when the projectile is still moving slowly, the pressure due to friction will be correspondingly low, the pressure gradually falls until the muzzle is reached, and it is therefore lower than with increasing rifling. The projectile then leaves the gun without any great disturbance from the rifling pressure. Further, as the band is engraved once for all with the angle it will have all along the bore the pressure is distributed equally over the driving face of the engraved ribs instead of being concentrated at the front of the ribs as in progressive or increasing rifling.

The following formulae giving the driving pressures for increasing and uniform rifling are calculated from Sir Andrew Noble's formula, which Sir G. Greenhill has obtained independently by another method.

Let \( R \) = total pressure, in tons, between rifling and driving band.

\( G \) = gaseous pressure, in tons, on the base of the projectile.

\( r \) = radius, in feet, of the bore.

\( \mu \) = coefficient of friction.

\( \rho \) = radius of gyration of projectile.

\( \delta \) = angle between the normal to the driving surface of groove and radius.

\( a \) = pitch of the rifling, in feet.

\( k \) = tangent of angle of rifling at any point of rifling.

\( M \) = weight of the projectile in pounds.

\( s \) = the length, in feet, travelled by the projectile.

For parabolic rifling

\[
R = \frac{2\rho(G + Mt)}{((2\rho + \mu)\sin \delta + 2\mu k_2 a (\rho - r) + (4\rho^2 s^2 k^2 + K^2))^{1/2}}
\]

For uniform rifling

\[
R = \frac{2\rho G}{((2\rho + \mu - r k) + (2\rho + \mu - r k) \sin \delta) + (1 + K^2))^{1/2}}
\]

For modern rifling \( \delta = 0^\circ \); therefore \( \sin \delta = 1 \); by which the above expressions may be considerably simplified.

For parabolic rifling

\[
R = 2(2(\rho^2 + k^2))(G + Mt) \]

For uniform rifling we can write \( h = 2\pi r \) and the expression reduces to

\[
R = \frac{\rho(1 + k^2)^{1/2}}{\mu}.
\]

Fig. 31 shows graphically the calculated results obtained for a 4-7-in. 50-calibre gun which has shot a travel of 173 ft.; the pressure

curve A is for a rifling twist increasing from 1 in 60 calibres at the breech to 1 in 30 calibres at the muzzle; curve B is for rifling having a uniform twist of 1 in 30 calibres.

In this example, with the increasing twist there is a loss of energy of about 11% of the total muzzle energy, and for the uniform rifling a loss of about 8%. This explains the reason for uniformly rifled guns giving a higher muzzle velocity than those with increasing rifling, supposing the guns to be otherwise similar.

The pitch of the rifling or the amount of twist to be given to it depends altogether on the length of the projectile; if this is short a small amount of twist only is necessary, if long a greater amount of twist must be arranged for, in order to spin the shell more rapidly.

Sir G. Greenhill has shown that the pitch of the rifling necessary to keep a projectile in steady motion is independent of the velocity, of the calibre, or of the length of the gun, but depends principally on the length of the shell and on its description, so that for similar projectiles one may roughly do for all guns.

Table I., on following page, has been calculated from Greenhill's formula.

In most modern guns the projectile is made in length from 3-5 to 4 calibres, so that the rifling is made to terminate at the muzzle with a twist of 1 turn in 30 calibres, which is found ample to ensure a steady flight to the projectile. In the United States a terminal twist of 1 in 25 calibres is often adopted; Krupp also uses this in some of his guns. With highpowder the projectile may be 4-5 calibres long, and the rifling has to be made of a quicker twist to suit.

If the gun has, as is usually the case, a right-hand twist of rifling the projectile drifts to the right; if it has a left-hand twist the drift takes place to the left. The drift increases with the range but in a greater ratio; further, the greater the twist (i.e. the smaller the pitch of rifling) the greater the drift. On the other hand, the smooth B.L. projectiles drift less than studded M.L. projectiles.

To find the angle, usually called the permanent angle of deflection, at which the sights must be inclined to compensate for the drift, a number of shots are fired at various ranges. The results obtained in this way are plotted on paper, and a straight line is then drawn from the point representing the muzzle through the mean value of the plotted curve.

The early guns were fired by inserting a red-hot wire into the vent, or by filling the vent with powder and firing it by a red-hot iron. Slow match held in a dealt stick afterwards took the place of the hot iron, and this again was replaced by a port-fire. Filling the vent with loose powder was inconvenient and slow, and to improve matters the powder was placed in a paper, tin or quill tube.
which was simply pushed into the vent and fired by the slow match or port-fire. The first attempt to fire guns by mechanical means was made in 1781 by Sir Charles Douglas, who fitted flint locks, similar to musket locks, but with the trigger actuated by a lanyard, to the guns on board his ship H.M.S. "Duke." A double flint lock introduced in 1818 by Sir Howard Douglas, K.A., continued to be used until about 1842, when it was replaced by a percussion lock invented by an American named Hiddens. In this lock one pull on the lanyard caused the hammer to fall and strike a percussion patch or cap hung on a small hook over the vent, and afterwards caused the hammer to be drawn backwards out of the way of the blast from the vent. These somewhat clumsy contrivances were swept away on the adoption in 1853 of fire tubes (see AMMUNITION), which had simply to be placed in the vent and the friction bar withdrawn by means of a lanyard.

Fricion tubes continued to be used with all muzzle-loading ordnance except in one or two nature of which the charge was ignited axially at the breech of the gun. In these a vent sealing friction tube retained in the vent by a tube holder was employed. With breech-loading field guns ordinary friction tubes were also used until the introduction of cordite, which eroded the vents so quickly by the escape of the gases that vent sealing tubes became a necessity. In all other breech-loading ordnance and with the latest pattern field guns the firing gear forms part of the breech mechanism.

All modern breech mechanisms form two groups: (a) the sliding type as in the Krupp wedge system, (b) the swinging type as in the interrupted screw system. Either type may be used with B.L. guns (i.e., those with the charge not contained in a metallic cartridge case) and Q.F. guns (i.e., those with charges enclosed in a cartridge case).

Sliding mechanisms may be divided into two forms: (1) those having the block or wedge sliding horizontally, and (2) those in which the block works in a vertical direction. (1) is that used principally by Krupp; (2) is best illustrated by system for small Q.F. guns; the Nordenfelt, Skoda and the Driggs-Schroeder mechanism for small Q.F. guns are adaptations of the same principle.

The Krupp gear is in reality an improved Cavallari mechanism; it is capable of being worked rapidly, is simple, with strong parts not liable to derangement, except perhaps the obturator. The breech end of the gun, however, occupies valuable space especially when these guns are mounted in the restricted turrets or gun houses on board ship. Later it will be seen that owing to the difficulty of arranging a convenient and efficient obturating device for the smokeless nitropowders, which have a peculiarly severe, searching effect, a metal cartridge case has to be used with even the smallest guns; naturally this assumes large dimensions for the 305 m.m. gun.

The wedge (fig. 32) is housed in the breech piece, which covers the breech part of the barrel, made very massive and extended to the rear of the barrel. A slot, cut transversely through the extended part of the breech block, formed a seat for the sliding block. The block is made so that its face is a plane surface perpendicular to the axis of the gun, while the rear is rounded and slightly inclined to the axis. One or more ribs similarly inclined on the upper and lower surfaces of the slot guide the breech breech block in its movement. For traversing the block a quick pitched screw is fitted to its upper surface and works in a nut attached to the upper part of the slot. This screw is dispensed with, as the block can be easily moved by hand, but the retaining nut of the sliding block is replaced so that there is a tendency for the block to be moved sideways, when the gun is fired by the pressure in the chamber acting on the front face of the wedge; this is prevented by a locking gear, consisting of a cylinder, having a series of interrupted collar, which bears against the screw. When the breech has been traversed into position, the collars are rotated, by a cross handle at the side of the block, into grooves cut in the rear surface of the slot; a further movement makes the screw jam the collars hard in contact with the gun and the block is sealed. With small guns having no a swelling, a strong screw takes the place of the collars, and on the handle being turned enters a threaded portion of the slot, actuates the breech for the last (or first in opening) portion of its movement in closing and secures it. To open the gun it is only necessary to reverse the screw. The gun is fired by a friction tube, screwed into an axial vent bored through the sliding block, or, in field guns, by a copper friction tube through an oblique vent drilled through the top of the breech end of the gun and through the block.

There is also fitted in some guns a percussion arrangement for firing, a percussion tube. The obturation is effected by a Broadwell ring or some modification of it; this is placed in a recess cut in the gun and rests against a hard steel plate fitted in the breech block.

For modern Krupp mechanisms, for use with cartridge cases, the arrangement (fig. 33) is very similar to that described above, but some improvements have been added to its simplicity. The transporting screw is fitted with a strong projection which, at the end of the movement for closing the breech, locks with a recess cut in the upper surface of the slot and secures the breech. The extra locking device is consequently dispensed with. The firing gear consists of a striker and a sliding wedge (b) driven by a screw (c). The striker is pushed back by a lever contained in the block and, on release, is driven forward against the primer of the cartridge case by a spiral spring.

Hitchkiss gun the mechanism has a vertical breech block of a rectangular section. The actuating lever F (fig. 34) is on the right side of the gun, and connected to a powerful crank arm C working in a groove E cut on the right side of the breech block. Below the lever is the lever best suited to follow the forming of the block A and extracts the fired case by extractor X, which is actuated by a cam groove Y cut on one side or on both sides of the block. As the mechanism is engaged the hammer H is cocked ready for the next round. To close the mechanism is pushed out to the front, and by releasing the striker arm by pulling the lanyard the hammer falls and fires the cap of the cartridge case.

Automatic gear is now generally fitted which permits the breech as the gun runs up after recoil and extracts the fired case by means of a supplementary mechanism and strong spring actuated by the recoil of the gun, and on pushing a new cartridge into the gun the breech which was retained by the extractor is released and closes automatically.
The Nordenfelt mechanism consists of a breech block (fig. 35) and a wedge to secure it. A hand lever on the shaft is pulled to the rear, and this works the action cam, which pulls down the wedge; the breech block is then caused to rotate and falls back to the rear. This motion of the breech block actuates the extractor and extracts the case. While the wedge is being withdrawn the firing pin is pulled back and cocks for the next round. The mechanism is closed by reversing the hand lever; this rotates the breech block upwards and pushes home the cartridge case, and the wedge is then forced up and secures the breech block.

These small type Q.F. guns, which were introduced to cope with torpedo boats, are, however, of little account, since experiment has proved that nothing smaller than a 12-pounder is sufficient so to injure a modern torpedo boat as to stop it. Most of these small guns are therefore in the English and in some other Services being converted into "sub-calibre" guns for exercise purposes. These sub-calibre guns retain their ordinary breech mechanism, but the bore is fixed at the strong steel plug screwed on the outside in a similar manner to the breech screw of the parent gun. The sub-calibre gun is placed in the parent gun and the screwed plug engages in the threads of the breech opening.

The idea is ingenious, and the result is that the repelling power required by a vessel against torpedo attack. The 12-pounder Q.F. 40-calibre guns were replaced by the more powerful 12-pounder Q.F. 50-calibre gun; this again by the 4-inch high power gun of 50 calibres, and now 6-inch guns are being used.

One other form of mechanism is of importance owing to its adoption for the 75 mm. French long recoil field gun (see below: Field equipments). This mechanism is on the Nordenfelt eccentric screw system and is very similar to that proposed by Clay about 1860; it has a breech screw (fig. 36) of large diameter mounted in the breech opening, which is eccentric to the bore. For loading, the breech block has a longitudinal opening cut through it, so that when the mechanism is in the open position this opening coincides with the chamber, while a half turn of the screw brings its solid wedge OP opposite the chamber and closes the gun. The mechanism is very simple and strong, and it is only adaptable for small Q.F. guns using cartridge cases; the firing gear is similar to that applied to other types of mechanism, and the fired case is extracted by an extractor actuated by the face of the breech screw as it is opened.

With the swinging type of breech mechanism with barrel, many of undoubted merit and claiming certain advantages, and all showing the vast amount of ingenuity expended in so designing them that they may be as simple, and, at the same time, as effective and quick acting as possible. It is impossible to deal with all these, and therefore only the more important systems will be described. The special feature of this type is that the breech opening is cut in the breech block by an interrupted eccentric screw; the screw is either supported in a carrier ring or tray hinged near the breech opening, or on a carrier arm which is hinged near the outer circumference of the gun.

The screw may be of the cylindrical interrupted, Welin and coned types; these, or their modifications, practically embrace the various forms used. The cylindrical form (fig. 37) is the simplest; it consists of a strong screwed plug engaging with a corresponding screw thread cut on the interior of the breech opening of the gun. The screw surface of the breech plug is cut away in sections equally divided and alternating with the threaded portions. The screw surface of the breech opening is similarly cut away, so that the plug can be pushed nearly home into the opening without trouble; by then revolving the breech screw through a small angle the screwed portions of the plug and breech opening engage. Thus if three screwed sections alternate with three plain sections the angle of revolution necessary to ensure a full engagement of the screw surfaces will be 60°. The Welin screw (fig. 38) is an ingeniously adaptation of the cylindrical type; in this the surface is divided into a pair of two or three cylindrical screwed sections and plain portion; thus if there are three sections, each section of which has one plain division and two screwed portions and three plain.

The breech opening is correspondingly formed so that the screwed threads would fully engage with 40° of movement. There is consequently a greater amount of screwed circumferential surface with the Welin screw than on the ordinary cylindrical interrupted type; the latter form has 50° screw surface while the Welin has 60°. For equal screw surface the Welin can therefore be made shorter.

For medium guns the Elswick type of coned screw (fig. 39) has found much favour, and this mechanism has been fitted to guns of all calibres from 3-inch to 6-inch, both for the British and numerous other governments. The coned screw breech is formed with the front part conical and the rear cylindrical, to facilitate its entrance into the gun, and also its exit; this form, moreover, is taken advantage of by cutting the interruptions in the screwed surface alternately on the coned part and on the cylindrical part, so that there is a screwed surface all round the breech screw. By this means the stress is taken all round the circumference, both of the breech screw and in the gun, instead of in portions alternately, as with other forms.

The Bofors breech screw is a modification. The surface is formed of a truncated ogive instead of a cylinder and cone, and the threaded portions are not alternate.

In the older type of mechanisms for heavy B.L. guns the breech was opened in from three to four different operations which involved considerable loss of time. Fig. 40 shows the general type for 9.2-in., 10-in. and 12-in. B.L. guns. To open the breech the cam lever C was folded up so that it engaged the pin B in connexion with the ratchet lever E. This was worked and so disengaged the breech screw from the threads cut in the gun; the cam lever was then released down to start the breech screw, and the winch handle Q rotated and so withdrew the screw and swung it clear of the breech opening. During these operations the firing lock was actuated and made safe, but the fired tube had to be extracted by hand. To close the gun these various operations must be reversed, and to open or close the gun would certainly occupy at least half a minute with ordinary men.

To compare with this a modern 12-in. breech mechanism is shown in fig. 41. In order to open this breech it is only necessary to turn
the handwheel continuously in one direction, and to close it again the motion of the handwheel is simply reversed; either closing or opening the breech by hand occupies about 6 seconds. Supposing the breech closed, the handwheel when rotated gives motion to the link G through the worm wheel S and crank F. By this means the obturation, for either operating the needle, which draws the breech ring. so to tooth the opening the 202 order for primer. A breech motion handwheel G is operated on opening of the breech ring out of the breech; the carrier ring and breech screw are revolved together to the right, clear of the breech opening.

In a modern 6-in. gun fitted with de Bange obturator all these operations are combined and the mechanism (fig. 43) worked by a horizontal hand lever which is moved from left to right through an angle of about 200°. The hand lever A moves a link B connected to a pin C on the breech screw D and disengages the screw from the gun; a small lateral movement is then given to the axis pin of the carrier so as to allow the obturator pad E to swing out of its seating; when Fig. 35.—Nordenfeldt Q.F. Breech Mechanism.

Fig. 36.—Eccentric Screw, Breech Mechanism.

promisquette without change. In the new mechanisms the breech had to be closed first, and the firing tube inserted after.

With smaller guns the mechanism is simpler, as less power is required for opening the breech. Thus, with the 6-in. B.L. gun Mark IV., introduced about 1885 (fig. 42) the breech is opened in three separate operations—(a) the cam lever, which also locks the breech, is raised into the vertical position and pulled over to the left; this disengages the screw threads; (b) the cam lever is folded down so that the cam acting on the rear face of the gun releases the de Bange obturator, and the screw is then pulled by hand through the carrier ring out of the breech; (c) the carrier ring and breech screw are revolved together to the right, clear of the breech opening.

With both these types of mechanism the de Bange system of obturation, with the pad only slightly coned, is used.

In a modern 6-in. gun fitted with de Bange obturator all these operations are combined and the mechanism (fig. 43) worked by a horizontal hand lever which is moved from left to right through an angle of about 200°. The hand lever A moves a link B connected to a pin C on the breech screw D and disengages the screw from the gun; a small lateral movement is then given to the axis pin of the carrier so as to allow the obturator pad E to swing out of its seating; when

Fig. 34.—Hotchkiss Q.F. Breech Mechanism.

tooth B is moved from its extreme left position to the right, and so disengages the breech screw A from the threads in the gun; the rack A' on the breech screw then comes into gear with the pinion E and draws the breech screw out of the gun into the carrier ring C, which finally swings on the axis pin and clears the breech opening. While the opening is being performed the firing lock L is operated by the cam groove A'; this puts the firing mechanism, either electric or percussion, to safety by withdrawing the firing needle, extracts the fired tube and leaves the primer chamber open for a fresh primer. All these operations are performed in the reverse order on closing.

With both these types of mechanism the de Bange system of obturation, with the pad only slightly coned, is used.
The breech mechanism for Q.F. guns firing metallic cartridge cases is worked on similar principles, but is somewhat simpler than that for the de Bange obturator, due principally to the fact of the firing primer being already contained in the cartridge case when this is introduced into the gun.

In the English service the later patterns of breech mechanism for medium and heavy B.L. guns have a Welin screw, with a "steeple cone" de Bange obturator, supported on a carrier arm. This arrangement allows the mechanism (fig. 44) to swing clear of the breech opening immediately the threads of the breech screw are disengaged from those in the breech in a similar manner to the Q.F. guns fitted with a cone screw. The mechanism is actuated by the handwheel L which rotates the hinge pin; this in turn, through gearing, moves a crank arm D connected, by a link B, to the pin on the breech screw. By continuously moving the handwheel the link B is drawn towards the hinge pin until the breech screw threads are disengaged; the catch C then drops into a pocket on the breech screw and fixes it to the carrier arm. The whole of the mechanism then rotates around the hinge pin and leaves the breech open ready for loading. As the breech screw threads are being disengaged the electric or percussion lock W is operated by a cam groove in a similar manner to that already described. In the latest modification of this mechanism a roller at the end of the crank arm D works a long lever connected to the breech screw by two pins. This forms what is termed a "pure-couple" mechanism and it is claimed that greater ease of working is ensured by its use. While the loading is going on a new firing tube is placed in the vent, so that on closing the gun, by turning the handwheel in the opposite direction, the gun is ready for firing. For 9.2-in. guns and those of smaller calibre the handwheel is replaced by a hand lever pivoted on the carrier (fig. 45). By giving this lever a single motion from left to right the mechanism is opened.

For 6-in. and 4-in. guns a shot support is attached to the breech face which is operated by the breech mechanism so that when the breech is open the shot support is in position for loading, and it falls out of the way when the breech is being closed.

In the larger types of all breech mechanisms ball bearings are employed in various parts, such as the hinge pin bearings, &c., to reduce friction and in most of the modern heavy guns on board ship the breech mechanism is arranged to be worked by a hydraulic cylinder placed on the breech face, or by a small hydraulic engine or electric motor placed in some convenient position on the mounting. The hand gear, however, is always retained for emergency and a clutch is provided so that it can be put into action at a moment's notice.

The Welin screw is largely used in the United States, but in heavy guns the ordinary cone (not "steeple cone") de Bange obturator is employed. The screw is mounted either in a carrier ring or on a carrier tray. In France the ordinary type of interrupted screw is adopted and this rests in a carrier tray. The operations of opening and closing are very similar to those already described.

All the recent patterns of mechanism have an extractor fitted to extract the empty cartridge case with Q.F. guns or the fired tube with B.L. guns. In Q.F. field guns it generally takes the form of a lever working on an axis pin. The longer arm of the lever is formed into a jaw which rests on the inner face of the breech opening beneath the rim of the cartridge case, and the short arm is so arranged that when the breech is opened the carrier, in swinging the mechanism, or the breech block itself, in sliding systems, suddenly comes in contact with it; the long arm is thus jerked backwards and extracts the case. In B.L. mechanisms the tube extractor is arranged on the same principle but in this case usually forms part of the box slide, i.e. that portion of the mechanism attached by interrupted collars to the rear end of the vent axial, in which the firing lock slides as it is actuated by the opening or closing of the breech mechanism. When the breech is being opened the firing pin of the lock is drawn back to safety and the lock is moved aside from over the tube; a tripper then actuates the extractor and ejects the fired tube. The extractor and tripper are so contrived that when a new tube is pushed home the extractor is also pushed back into the closed position, or, if the tube is somewhat stiff to insert, the action of closing the mechanism moves the lock over the primer and forces it home.

The firing lock used in B.L. guns is an important part of the mechanism. They are all designed on the same principle, with a view to safety and rapidity, and may be regarded as a miniature sliding breech mechanism. In the older types the lock or its substitute was manipulated by hand, and with electric firing the wires from the tubes were joined up to the loose ends of the firing circuit;
safety depended therefore on everything being in order and all operations correctly performed. The gun could, however, be fired before the breech was properly secured and a serious accident caused; to prevent this all the movements of modern locks are arranged to be automatic, and wireless electric tubes are used so that immediately the breech mechanism commences to open, the lock itself is moved in the box slide so as to uncover the vent opening. During the first part of this movement a foot on the
striker rides up an incline \( I \) (fig. 45) on the box slide and thus pushes back the striker from contact with the tube. The extractor described above is actuated at the same time. Most locks consist of a steel frame with a socket for containing the striker and main spring. They are contrived so as to be capable of firing both electric and percussion tubes, but others are arranged for firing only electric, separate locks being employed for use with percussion tubes. The construction of both is very similar, but with the percussion lock, or the combined lock, a trigger is provided which drops into a notch in the striker when this is pulled back by the lugs E E (fig. 45) on the outer attachment of the striker. On the trigger being pulled by a lanyard the striker is released and fires the tube.

For Q.F. guns with interrupted or coned breech screws the striker is contained in the breech screw, but, in order to provide for safety, a small lever cam or other contrivance is fitted which, when the breech is closed, engages the hand lever and withdraws the striker from contact with the primer inserted in the cartridge case. The striker consists of a steel needle, with the stem insulated by ebonite or some similar material, contained in an outer steel sheath. The sheath is formed with a foot or lug which is actuated by the safety gear; a collar is also provided for taking the thrust of the main spring.

Another form of lock now much in favour, especially for field-gun mechanisms, is that known as a trip lock. It is mainly used for percussion firing but can also be combined for use with electric tubes. In this pattern the striker is withdrawn, cocked and released by the continuous pull of a hand lever attached to the mounting or by a lanyard attached to the lock. Should a misfire occur the striker may be actuated as often as necessary by releasing the hand lever or lanyard and again giving a continuous pull (fig. 46).

In all modern heavy guns, especially when firing to windward, there is a tendency, when the breech is opened rapidly after firing, for a sheet of flame to issue from the open breech. It was practically unknown with the old black powders, but is of frequent occurrence with all smokeless propellants. If the gun is loaded immediately after the breech is opened the fresh charge may be ignited and an accident caused. Several serious accidents have already been traced to this cause, notably one on the United States battleship "Missouri" on 13th April 1904, when 33 lives were lost. The flame is due to the large amount of highly heated carbonic oxide remaining in the gun from the explosion of the charge; this mixing with the oxygen of the air when the breech is opened burns rapidly as a sheet of flame in rear of the gun, and should wind be blowing down the gun the action is more intense. By looking into the gun from the muzzle, before the breech is opened, the gas can often be seen burning with a pale-blue flame as it slowly mixes with air and a curious singing noise is heard at the same time. It is now usual to fit a special apparatus on the gun, so that directly the breech is partly opened a blast of compressed air is allowed to enter the rear end of the chamber and thus sweep the whole of the residual gas out at the muzzle.

The purpose of the obturator is to render the breech end of the gun gas-tight, and to prevent any escape of gas past the breech mechanism. In the first Armstrong B.L. gun this object was attained by fitting to the breech block a copper ring coned on the exterior; the coned surface was forcibly pressed by screwing up the breech screw against a corresponding copper ring fitted at the breech opening of the gun chamber. It is only possible to use this method when the copper surfaces can be jammed together by a powerful screw.

Except the above, all obturators in use are arranged to act automatically, i.e., the pressure set up in the gun when it is fired expands the arrangement and seals the opening; immediately the projectile leaves the bore the pressure is relieved and the obturator, by its elasticity, regains its original shape, so that the breech mechanism can be opened or closed with ease. In the French naval service B.L. guns have been in use since 1864, and the system of obturation was arranged on the same expansion principle as the leather patching ring of the hydraulic press. A steel ring A (fig. 47) of cupped form was fastened by a screwed plug to a thick steel plate, carried on the face of the breech screw, so that it could rotate when the breech screw was rotated in opening or closing the gun. The gas out of the cup fitted against a slightly coned seating formed in the breech end of the gun chamber. When the gun was fired, the gas pressure expanded the cup ring and forced it into close bearing against the seating in the gun and the thick steel plate on the breech screw, thus preventing any escape of gas. Very similar to this was the Elswick cup obturator (fig. 48) introduced by the Elswick Ordnance Company in 1881; its rear surface was flat and it was held by a central bolt against the front of the breech screw which was slightly rounded. The cup yielded to the gas pressure until it was supported by the breech screw; this action expanded the lip against a copper seating, let into the gun, which could be renewed when necessary. Many of both types are still in use and act perfectly efficiently if carefully treated. The use of modern smokeless powder renders them and similar devices, such as the Broadwell ring (fig. 49), &c., peculiarly liable to damage, as a slight abrasion of the lip of the cup or ring, or of its seating, allows gas to escape, and so accentuates the defect with each round fired. Unless, therefore, the fault is immediately remedied considerable damage may be caused to the gun. The Broadwell gas ring is still in use in the French naval service, where it is made of copper (fig. 50), and also of steel in a modified form (Płorkowski) in the German service (fig. 51); the last-named service, owing to the defect already named, all the latest guns, both light and heavy, use metal cartridge cases. In the French navy, as in
most other services, cartridge cases are used for the smaller and medium guns only.

One of the most efficient obstructions not liable to damage is the plastic device introduced by Colonel de Bange of the French service and adopted by the British and other governments. It consists of a pad (fig. 52) made up of a strong annular-shaped canvas bag A, containing a mixture of asbestos fibre and mutton suet; the bag with its contents is placed in a properly formed die and subjected to hydraulic pressure by which it becomes hard and firm. The pad so made is then placed on the front of the breech screw B, and it is protected on its faces by disks C, C, of metallic tin or copper having steel wedge rings on the outer edges; the circumference of the complete pad and disks is steel wedge ring into which the axial head fits. On firing the gun the head is forced into the wedge ring and expands it against the seating in the gun.

One other means of obstruction has to be considered, viz., metallic cartridge cases. These are made of a kind of brass; aluminium cases have been experimented with, but have not proved satisfactory. The case (fig. 54) acts on the same principle as the cup obstruction and is extremely efficient for the purpose; moreover, they have certain advantages conducive to rapid firing when used for small guns. The idea has been adopted in some cases in small arms, and larger cartridges of the same type were introduced for 3-pounder and 6-pounder guns by Hotchkiss and Nordenfelt about the year 1890 for the purpose of rapid firing against torpedo boats. Then in 1886 the Elswick Ordnance Company produced a 36-pounder (soon converted to a 45-pounder) of 4.7-in. calibre, with the powder charge contained in metallic cases, and about 1888 a 6-in. 100-pounder gun using similar cartridges.

A special advantage of the cartridge case is that it contains the firing primer by which the charge is ignited and consequently renders the firing gear of the gun more simple; on the other hand, should a miss-fire occur the gun must be opened to remove the primer. This is a proceeding liable to produce an accident, unless a long enough time is allowed to elapse before attempting to open the breech; guns having de Bange obturators and firing tubes inserted after the breech is closed are therefore safer in this respect.

Some means of extracting the case after firing must be fitted to the gun; this is simple enough with small guns, but with those of heavy nature the extractor becomes a somewhat ponderous piece of gear.

Metallic cases of a short pattern have been tried for large calibre guns; although their action is quite efficient, they are difficult to handle, and if a case must be used it is preferable to employ a fairly long one. It was for this reason that, in England up to 1898, it was considered that a gun above 6-in. calibre the de Bange obstruction was the most advantageous. Since then the de Bange obturator has been employed in guns of 4-in. calibre and above, the cartridge case being retained only for 3-in. and smaller guns. Krupp, however, uses cartridge cases with all guns even up to 12-in. calibre, with the cartridge case being retained only for 3-in. and smaller. Krupp, however, uses cartridge cases with all guns even up to 12-in. calibre, with the cartridge case being retained only for 3-in. and smaller. Krupp, however, uses cartridge cases with all guns even up to 12-in. calibre, with the cartridge case being retained only for 3-in. and smaller.

In the most modern Krupp 12-in. guns the charge is formed in two pieces; the piece forming the front portion of the charge is contained in a consumable envelope, while the rear portion is contained in a brass cartridge case, which forms the obturator, about 45 in. long.

It will be seen that such large and heavy cases add to the difficulties which occur in handling or storing the ammunition of large calibre guns, and although the use of cartridge cases with small guns is not rare in the case with heavy guns. It seems, therefore, that the balance of advantages is certainly in favour of the de Bange system, for all guns except those of small calibre. With ordnary field guns cartridge cases are now considered obligatory owing to their convenience in loading.

While the ordinary types of plastic obturators last for an indefinite time a cartridge case can be used for a limited number of rounds only, depending on the power of the gun. If two or more guns are fired from ten to twenty rounds or even more may be fired from one case if care is taken to reform it after each round; with large guns they will not, of course, fire so many. Cartridge cases are an expensive addition to the ammunition, so that there should be no doubt about the advantages they offer before they are definitely adopted for heavy guns.

The rapidity with which modern guns can be fired and the enormous energy they develop is especially striking when one
considers the same facts in connexion with the early guns. Favé states in his Histoire et tactique des trois armes (p. 33) that during the invasion of Italy in 1494 by Charles VIII, the guns were so unwieldy and the firing so slow that the damage caused by one shot could be repaired before the next could be fired. The range, too, about 100 yds. for battering purposes, now seems absurdly short; even at Waterloo 1200 yds. was all that separated the antagonists at the commencement of the battle, but they approached to within 200 or 300 yds. without suffering serious loss from either musketry or gun fire. Nelson fought his ships side by side with the enemy’s; and fifty years after Nelson’s day a range of 1000 yds. at sea was looked upon as an extreme distance at which to engage an enemy. Contrast this with the range of 12,000 yds. at which the opposing Russian and Japanese fleets more than once commenced a naval battle in 1904, while the critical part of the action took place at a distance of 7000 yds.

These long ranges naturally intensified the requirements of the British and other navies, and, so that they shall not be outclassed and beaten by an enemy’s long-range fire, guns of continually increasing power are demanded. In 1900 a 12-in. gun of 40 calibres was considered all that was necessary. After the Russo-Japanese War the demand rose first for a 45-calibre gun and then for a 50-calibre gun, and muzzle velocities from about 2400 ft. to about 3000 ft. In 1910 greater shell power was demanded, to meet which new type guns of 13.5-in. and 14-in. calibre were being made.

In the days of M.L. heavy guns one of the most difficult problems was that of loading. The weight of the shell and powder was such that some mechanical power had to be employed for moving and ramming them home, and as hydraulic gear had by that date been introduced it was generally used for all loading operations. To load, the guns had to be run back until their muzzles were within the turret, or, in the case of the 16-in. 80-ton guns of H.M.S. “Inflexible,” until they were just outside the turret. The guns were then depressed to a fixed angle so as to bring the loading gear, which was protected below the gun deck, in line with the bore; the charge was first rammed home and then the projectile. With this arrangement, and in order to keep the turret of manageable dimensions, the guns had to be made short. Thus the 12.5-in. 38-ton M.L. gun had a length of bore of but 16 calibres, and the largest English service gun of 16-in. diameter had a bore of 18 calibres in length; while the largest of the type weighing 100 tons, built by Sir W. G. Armstrong & Co., for the Italian navy, had a bore of 17.72 in. and a length of 20 calibres. The rate of fire was fairly rapid—two rounds could be fired from one turret with the 12.5-in. guns in about three minutes, while it took about four minutes to fire the same number from the 80-ton and 100-ton gun turrets.

The possibility of double loading M.L. guns was responsible for the bursting on the 2nd January 1879 of a 38-ton gun in a turret on H.M.S. “Thunderer”; and it was partly due to this accident that B.L. guns were subsequently more favourably regarded in England, as it was argued that the double loading of a B.L. gun was an impossibility.

With the B.L. system guns gradually grew to be about 30 calibres in length of bore, and they were not made longer because this was considered a disadvantage, not to be compensated for by the small additional velocity which the old black and brown prismatic powders were capable of imparting with guns of greater length. Increase in the striking energy of the projectile was consequently sought by increasing the weight of the projectile, and, to carry this out with advantage, a gun of larger calibre had to be adopted. Thus the 12-in. B.L. gun of about 25 calibres in length gave place to the 13.5-in. gun of 30 calibres and weighing 67 tons, and to the 16.25-in. also of 30 calibres and weighing 111 tons. The 10,000- or 12,000-ton battleships carrying these enormous pieces were, judged by our present-day standard, far too small to carry such a heavy armament with their ponderous armoured machinery, which restricted the coal supply and rendered other advantages impossible; even the 24,000-ton battleships are none too large to carry the number of heavy guns now required to form the main armament.

The weight and size of the old brown prismatic charges had also reached huge dimensions; thus, while with heavy M.L. guns the weight of the full charge was about one-fourth that of the projectile, it had with heavy B.L. guns become one-half of the weight of the shell or even a greater proportion. The introduction of smokeless powder about 1890, having more than three times the amount of energy for the same weight of the older powders, allowed longer guns to be used, which fired a much smaller weight of charge but gave higher velocities; the muzzle or striking energy demanded for piercing hard-faced armour could consequently be obtained from guns of more moderate calibre. The 13.5-in. and 16.25-in. guns were therefore gradually discarded and new ships were armed with 12-in. guns of greater power. As the ballistic requirements are increased the weight of the charge becomes proportionately greater; thus for the

---

**Fig. 45.** Breech Mechanism for 6-in. B.L. Gun
present high velocity guns it has reached a ratio of about 0.4 of the weight of the projectile.

The progress of artillery and the improvements made in armour have been reciprocal; as the protective value of iron and subsequently of steel plates has increased, so the penetrative force or quality of the projectile has advanced. Often, after a period of apparent inactivity, fresh ideas or new metallurgical processes have enabled further progress to be made; this is of the projectile. This can be done to a limited extent with beneficial results, but it is impossible to carry the idea very far, as the projectile becomes very long and difficulties may be encountered with the rifling; or, if these are avoided, the thickness of the walls of the shell is increased so much that the heavier projectiles is in reality less powerful owing to its internal bursting charge being comparatively small. Again, many foreign gunmakers claim that their guns are, in comparison with English guns of the same power, of less weight. This is true in a limited sense, but such guns have nothing like the same factor of resistance as English guns, or, in other words, the English
guns are much stronger. This is an obvious advantage, but an equally solid one is the fact that owing to the greater weight of the home-made weapon the recoil energy is less and consequently as near the breech end as possible; by this means the radius of the gun house is reduced to the smallest dimension and, in consequence, there is a great saving of weight of armour. The extra weight of the gun is therefore more than compensated for.

Until late into the 16th century the calibres of the guns were not regulated with a view to the interchangeability of shot. In the following century ordnance was divided into classes, but even then, owing to no doubt to manufacturing difficulties, there was no fixed size for the bore. The Tables II.-VII. give some idea of the size and weight of these pieces.

Table II. is taken from Cleveland's Notes, but corrected from "An Old Table of Ordinance" (Proc. R.A.I., vol. xxviii. p. 365); the last column gives the range in scores of paces at point blank, a term used in those days to denote the first part of the trajectory which was supposed to be a straight line. Later the point-blank range was that distance from the gun on its carriage to the first graze of the shot on the horizontal plane when the gun was placed horizontal; this depended on the height of the gun above the ground plane, but it was the only method of determining the relative power of these early guns.

In power, smooth-bore guns in Europe did not differ very much from each other, and it may be taken for granted that the progress made since has been much the same in all.

D'Antoni, in his Treatise of Fire Arms (translated by Captain Thomson, R.A.), gives particulars of Italian guns of about 1746, which are shown in Table III. It will be seen that the velocities given in Table III. are not inferior to those obtained from guns actually in use in 1860 (see Table IV.). They were considerably higher than those for elongated rifled projectiles (Table V.) for many years after their introduction; the last-named, however, during flight only lost their velocity slowly, while the spherical shot lost their velocity so rapidly that at 2000 yds. range only about one-third of the initial velocity was retained.

aimed fire and no shooting is worth conaimed much depends on the quickness
with which the gun can be opened, loaded and closed again ready
for firing, but quite as much depends on the ease and convenience
of moving to any required direction the gun with its mounting;
also on the system of recoil adopted and the method of sighting.
Two identically similar guns may consequently give entirely
different rates of firing, unless mounted and sighted on the same
system without taking into consideration the personal element of
the gun detachment or crew. The rates of firing shown in many
tables are therefore not always a trustworthy criterion of the guns'

The advantage of, the Q.F. system {i.e. a gun firing
charges contained in metallic cases), when suitably mounted, over
the old B.L. guns was exhibited in a very marked manner in 1887,
when the first 4'7-in. Q.F. gun fired ten rounds in 47-5 seconds
and subsequently fifteen rounds in one minute. The 5-in. B.L. gun
when fired as rapidly as possible only fired ten rounds in 6 minutes
16 seconds; so that the Q.F. gun fired its tenth round before the
then service gun fired its second shot. Recent improvements made
in the mechanism of the B.L. gun. enable it to compete with the
Q.F. system.
The tabulated armour-piercing value of a gun is based on the
capabilities.

HISTORY AND CONSTRUCTION]

ORDNANCE

results given by various formulas. These often vary considerably, so in order that a direct comparison in the tables may be made, this value is obtained for wrought iron plate only, using Tresidder’s formula, which is one of the most trustworthy. The equivalent thickness of Krupp cemented steel armour can be obtained immediately by dividing the tabulated value for wrought iron by a “factor of effect” of 2·3 to 2·4 for uncapped armour piercing shot, and about 2·0 for capped armour piercing shell. These factors are dependent on the nature of the projectile and must therefore be taken as approximate.

Tables VIII.—XXI. are obtained from trustworthy sources, but as great secrecy is now observed in many countries there may be a few inaccuracies; in some cases the whole of the data are not available.

Table IX.—French Naval Ordnance, 1910.

**Note.**—The Japanese fleet has mainly been armed by Armstrong's Works, but the "Katori" was armed by Vickers', and those ships taken from the Russians during the late war are armed with guns from Krupp or Obuchoff. Guns of all sizes are now, however, being constructed in Japan, so that the country is no longer dependent on foreign factories.

Note.—The above table includes a light and heavy type of gun, but for each the length of bore is 50 calibres, in the unabridged table guns of 40 and 45 calibres are included. The particulars of the shorter pieces can be easily obtained from Table XXI., as the
construction of Krupp's complete table is based on very simple rules. Thus, for the same relative length of gun, the weight of the projectile and of the charge are, with few exceptions, in proportion to the cube of the calibre. Again, the weight of the gun varies as the cube of the calibre multiplied by the length. The muzzle velocity is practically identical for guns of the same relative length, and varies as the square root of the length; consequently the muzzle energy varies directly as the length. Two weights of projectile are given for every gun, but the muzzle energy of each, for the same charge, is identical; this result is never the case in actual practice. Similar arithmetical processes are utilized for the Schneider-Canet, Bofors and Skoda tables, and only the first named is therefore given.

**Note.**—The most powerful gun of each calibre has been selected.

Modern naval artillery may be looked upon as the high water mark of gun construction, and keeps pace with the latest scientific improvements. For coast defence the latest pattern of ordnance is not of the same importance; in general very similar guns are employed, although perhaps of an older type. Formerly in the British Service the heaviest guns have been used for this purpose; but of late years, where fortifications could be erected in suitable situations, the largest gun favoured is the 9-2-in. of the latest model. Other governments have however selected still heavier pieces up to 12-in. calibre, mounted in heavily armoured cupolas or gunhouses.

As regards field material, mobility is still one of the primary conditions, and, as high power is seldom required, ordnance of medium calibre is all that is necessary. For siege purposes guns of 4-in. to 6-in. calibre are generally sufficient, but howitzers up to 28 cm. (11-02 in.) were used at the siege of Port Arthur, 1904. All authorities seem agreed that for ordinary field guns 75 mm. or so is the smallest which can be efficiently employed for the purpose, and the muzzle velocity is in nearly all equipments about 500 m.s. (1640 f.s.).

For mountain equipments all foreign governments have selected a 75-mm. gun with a velocity of about 350 m.s. (1148 f.s.); in England, however, a 2-75-in. has been supplied to mountain batteries; this fires a projectile of 10 lb with 1440 f.s.

Field Howitzer batteries abroad have pieces of from 10 to 12 centimetres calibre and a low velocity; in England a 5-in. howitzer is at present used, but it is intended to adopt a 4-5-in. howitzer of 17 calibres in length for future manufacture.

Heavy shell power and long range fighting render the work of the gun designer particularly difficult, especially when this is combined with conditions restricting length and weight; and, in addition, other considerations, especially for naval guns, may have to be taken into account such as the allowable weight of the armament, and the size of the gun house or turret. These and other similar conditions are important factors in deciding on the type of design which embodies most advantages for a heavy gun intended for the main armament. For land defence more latitude is allowed so long as this is combined with economy. With both heavy and medium naval guns the length is often limited to 45 calibres on account of peculiarities in the design of the vessel, but usually great rapidity of fire, high velocity and large shell power are insisted upon. Again for Q.F. field guns, where high velocity is not of importance, ease of manipulation, rapidity of working and reliability even after months of arduous service are essential. Supposing, however, that the initial conditions, imposed by the shipbuilder or by the exigency of the case, can be fulfilled, it still remains to so design the gun that, when it is fired, there is an ample margin of safety to meet the various stresses to which the several portions of the structure are subject. The two principal stresses requiring special attention are the circumferential stress, which tends to burst open the gun longitudinally, and the longitudinal stress. The calculation for the last named is based on the supposition that the gun is a hollow cylinder, closed at one end by the breech screw and at the other by the shot, both being firmly fixed to the cylinder. The gas pressure exerts its force on the face of the breech screw and on the base of the shot thus tending to pull the walls of the cylinder asunder. But besides these there is the special stress on the threads of the breech screw which must receive very careful consideration.

Regard must also be had to the fact that in building up the gun, the smaller the diameter of the hoop and the longer it is, the higher must be the temperature to which it is heated before shrinking. This is necessary in order that the dilatation may allow sufficient clearance to place the hoop correctly in position on the gun, without the possibility of its contracting and gripping before being so placed. Should it warp while being heated or while
being placed in position the hoop may prematurely grip on the gun and may consequently have to be sacrificed by cutting it off and shrinking on another.

The dilatation must be so adjusted that the required temperature to obtain it is not higher than that used for annealing the forging, otherwise the effect of this annealing will be modified. There is, therefore, an added risk in shrinking up hoops of small diameter.

Before heating hoops of large diameter two or three narrow reference bands are turned on the exterior and their diameter measured; special gauges are prepared to measure these plus the dilatation required. After heating the hoop but before shrinking it, the diameter of the reference bands when tested by these gauges should not be in excess of them. The temperature can then be easily ascertained by dividing the dilatation by the coefficient of expansion of steel per degree F. or C., taking of course the diameter into account.

For small hoops this method is not convenient, as the hoop cools too quickly; the dilatation must then be obtained by ascertaining the temperature, and this is best done by the use of some form of pyrometer, such as a Siemens water pyrometer, before the hoop is withdrawn from the furnace.

It may also be desired to obtain a given striking energy or velocity at some definite range—then, the weight of the projectile being decided upon, the muzzle velocity is found from the formulas (see Ballistics) given in Exterior Ballistics. From this and the length of the gun allowable the designer has, with the aid of former experience and formulas given in Internal Ballistics, to decide on the weight and nature of the powder charge necessary and the internal dimensions of the powder chamber and bore. These data are used to plot what is termed a "gunners' curve," i.e. the curve of pressures along the bore which the powder charge decided upon will give. The factor of safety and the maximum allowable stress of the steel forgings or steel wire also being known, the necessary strength of each section of the gun can be easily found and it remains to so proportion each part as to conform to these conditions and to meet certain others, such as facilities for manufacture, which experience only can determine.

When the second course consists of a single long tube into which a tapered barrel is driven, as in the system adopted by the English government, the two tubes are treated as a single tube equal in thickness to the two together; but when the second course consists of several tubes shrunk on to the barrel the additional strength, obtained by the initial tension of the shrunk tubes, is sometimes taken account of in the calculation, or the two may be treated as one thick tube.

The gunmakers' formulas for the strength of the gun are obtained from considering the strength of a thick cylinder exposed to unequal internal and external pressures. Supposing a transverse section of the gun to extend, the internal radius of the barrel is r, in., the external radius r_in., the external radius of the second course is r_2 and so on, and the external radius of the jacket is r_J. Then if T_a is a circumferential stress (tension) in tons per square inch, P_a is a radial stress (pressure) in tons per square inch, and P_m is a radial stress at radius r_m in., the formulas used in calculating the strength of the built-up guns are as follows:

\[ T_a = P_a \frac{r_a^2 - r_m^2}{r_a^2} \]

\[ P_a = \frac{r_a^2 - r_m^2}{r_a^2} \times P_m \]

where r_a is any intermediate radius in the thickness of a tube in the same tube; also the pressure between the (n-1)th and nth hoops is

\[ P_n = \frac{r_n^2 - r_{n-1}^2}{r_n^2} \times (T_{n-1} + P_m) + P_m \]

Equation (4) is usually known as the Gunmakers' formula and from it, when P_m and T_{n-1}, T_{n-2}, . . . are known the other pressures can be found. The proof of tension of the material is kept well below the yielding stress. For ordinary carbon gun steel it is usual to consider that the proof tension of the barrel should not exceed 15 tons and of the outer hoops 18 tons per square inch; with nickel steel these become 20 tons and 24 tons respectively. If the nth hoop is the exterior tube then P_m = 0; neglecting the atmospheric pressure.

In all gun calculations for strength three cases must be considered:

(a) When the built-up gun is fired, the stress is called the Firing Stress and is obtained by repeated use of equation (4).

(b) When the gun, supposed to be solid in the innermost block of metal is fired, the stress is termed the Powder Stress and is obtained from the equations (1) and (2);

(c) When the built-up gun is in reposition, the stress is then called the Initial Stress.

Between these three cases the following relations hold:

Initial Stress + Powder Stress = Firing Stress

(5).

It is best to use different symbols to distinguish each kind of stress. We will use for the Firing Stress P, it; for Powder Stress p, l; and for the Initial Stress (P, i).

The method of working will be illustrated by a practical example. Take, for instance, a section across the chamber of a 4.7-in. Q.F. gun, for which the diameter of the chamber is 5 in., that of the barrel 8.2 in., and that of the jacket 15 in.

Here

\[ n = 2; r_1 = 4; r_2 = 7.5 \]

\[ T_a = 15; T_l = 18; P_m = 0 \]

From (4) for the Firing Stress

\[ P_i = \left(7.5^2 - 4^2\right) \times 18 = 9.72 \text{ tons per square inch} \]

From (3) the tension T_o of the outer fibres of the hoops is obtained; thus

\[ T_o = P_i + T_l = 18.972 + 21 = 39.72 \text{ tons per square inch} \]

For any intermediate radius r the stress can be found by using equations (1) and (2) or (1) or (2) and (3).

For the Powder Stress equations (1) and (2) are used by putting

\[ n = 1, \text{ and } P_m = 0 \]

(6)

When \( r = r_2 = 2.5 \), \( l = 10 \), \( P_l = P_m = 0 \) already found and:

\[ t_o = \left(7.5^2 - 2.5^2\right) \times 21 = 26.25 \text{ tons} \]

For the tension of the fibres at the outer circumference

\[ t_o = 26.25 - 21 = 5.25 \text{ tons} \]

From (3) and for a radius \( r = 7.5 \) inches.

The stress for any intermediate radius r can be obtained from (6) or (7) or, from (6) or (7) and (3).

Subtracting the Powder Stress from the Firing Stress the Initial Stress is obtained, and the various results can be tabulated as follows:

<table>

</tr>
</tbody>
</table>

It is generally stipulated that the initial compression of the material at the inner surface of the barrel shall not exceed 26 tons. It is also held to be unsafe when shrunk together, give the stresses found by calculation. To do this the exterior diameter of the barrel must be a little larger than the internal diameter of the covering hoop; after this hoop is shrunk on to the barrel its exterior diameter is turned in a lathe so that it is slightly larger than the interior of the next course hoop and so on. It will be seen that the fibres of the barrel must be compressed while the fibres of the superimposed hoop are extended, and thus produce the Initial Stress. The shrinkage S may be defined as the excess of the external diameter of the tube over the internal diameter of the hoop, when separate and both are in the cold state. Then

</tbody>
</table>

As the wire is wound on, the pressure of the external layers will compress those on the interior, thus producing an extension in the wire which is equivalent to a reduction in the winding tension $\theta$ of the particular layer at radius $r$ considered. If $\tau$ represents this reduction then

$$\theta = \frac{\tau}{\tau - \rho},$$

where

$$\tau = \frac{r^2 + 2r_0^2}{r^2 - r_0^2}$$

At the interior layer of wire $r = \theta$ is the initial stress on the exterior of the barrel and the winding tension must commence at

$$\theta = \frac{11-875 + 18-525}{18-525} = \frac{30-4}{18-525} = \frac{2}{18-525}$$

As the jacket is supposed to have no shrinkage $T = 0$ and consequently

$$\theta = \frac{17-5}{18-525}$$

These winding tensions can be found directly from formula (14) and then

$$E = \frac{149-875}{18-525}; \quad F = 34-875; \quad G = 364-875$$

Sir G. Greenhill has put these formulas, both for the built-up and wire-wound guns, into an extremely neat and practical geometrical form, which can be used instead of the arithmetical processes for these see Text-Book of Gunnery, Treatise of Service Ordinance, 1893, and Journal of the United States Artillery, vol. iv.

The longitudinal strength of the gun is very important especially at the breech end and, if the wire is utilized to the portion of the gun the thickness of the barrel and the interlocking of the covering hoops provide ample strength, but at the breech special provision must be made. It is usual to provide for this by means of a strong breech piece or jacket in small guns or by both combined in large ones. Its amount is easily calculated on the hypothesis that the stress is uniformly distributed throughout the thickness of the breech piece, or jacket, or of both. If $n$ is the largest radius of the gun chamber, $n' = r_0$ the radius of the obturating seating, $n$ the external radius of the barrel, and $P_0$ the maximum powder pressure, then, with the usual form of chamber adopted with guns fitted with obturation other than cartridge cases, there will be a longitudinal stress in the barrel at the breech end of the chamber due to the action of the pressure $P_0$ on the rear slope of the chamber, of

$$P_0 \left( \frac{r^2 - r_0^2}{r^2 + r_0^2} \right)^2$$

this is resisted by the barrel of section $\pi \left( r^4 - r_0^4 \right)$ so that the resistance

$$R = \pi \left( r^4 - r_0^4 \right) P_0$$

This portion of the longitudinal stress is not of great importance as the breech end of the barrel is supported in all modern designs by the breech bush. In Q.F. guns, i.e. those firing cartridge cases, the breech end of the chamber has the largest diameter, and $r_0$ to $r_0$ so that there is no longitudinal stress on the chamber part of the barrel. For the breech piece or outer tube of radii $r_0$ and $r_1$, the resistance

$$R = \pi \left( r_0^4 - r_1^4 \right) P_0$$

for B.L. guns

$$R = \pi \left( r_0^4 - r_1^4 \right) P_0$$

If the longitudinal stress is taken by a jacket only, the resistance is found in the same way.

Generally for ordinary gun steel, the longitudinal stress on the material is always kept low to 2 tons per square inch for 13 tons for nickel steel; but even with these low figures there is also included a factor of safety of 1.5 to 2. In large guns it is best to consider the jacket as an auxiliary aid only to longitudinal resistance, as, owing to the necessary connexions between it and the breech bush and its distance from the point of pressure, there is a possibility that it may not be taking its proportionate share of the stress.

The thread of the breech screw and of the breech bush (or opening) must be so proportioned as to sustain the full pressure on the maximum obturating area; V or buttress shaped threads are always used as they are stronger than other forms, but V threads have the great advantage of centring the breech screw when under pressure.

In most modern B.L. guns fitted with de Bange obturation the
diameter of the seating is made just large enough to freely admit the projectile; this is usually considerably smaller than the maximum diameter of the chamber, consequently a less area is exposed to the gas pressure and less screw thread section is required.

The principal features of the various systems of construction of modern heavy guns may be briefly described.

Over the muzzle end two or three long tubes are shrunk; the chase hoop is also screwed to the barrel near the muzzle. A jacket is shrunk over the breech portion of the gun, and the breech bush is screwed in at the rear end. The gun is further strengthened by a long tube in front of the jacket to which it is attached by a screwed collar.

Fig. 57 shows the design adopted for the United States navy. Here the barrel is surmounted by a second course in two lengths, and over the breech a third and fourth layer are shrunk. The breech scut is screwed into the rear end of the second course.

Fig. 58 is the Krupp system, of which, however, it is an old example; it is believed, however, that Krupp still retains the essential peculiarities of this design, viz., that over the breech end of the barrel is shrunk a solid mass piece, made particularly massive where the breech wedge is seated. The remainder of the layers consist of hoops which are comparatively short but may be covered with longer thin tubes.

When guns are fired, the interior surface is gradually worn away by the action of the powder gases; the breech end of the rifled portion of the bore becomes enlarged, and the rifling itself partly obliterated. The ballistics suffer in consequence of the enlarged diameter of the bore, and the rifling may be worn so much as not to properly rotate the projectile. A modern gun design provision has, therefore, to be made for repairing or replacing the barrel when it is worn out. There are two methods of providing for the repair in the original design—the first is by replacing the whole of the barrel by an entirely new one; the second is to make the original barrel thick so that when it is worn the interior can be bored out, either over a portion of its length to cover the eroded part, or the full length for "through lining." In large guns it is usual to make the original barrel, if it is intended to be removed as a whole, tapered from end to end, so that by warming the gun in a vertical position breech downwards to about 300° F. and then suddenly cooling the barrel by a jet of water it can be knocked out by heavy blows from a falling weight. A new tapered barrel can then be inserted by driving it in. When a gun had originally a thick barrel is lined part of the barrel is bored out in a machine, and it is usual to make the hole tapered so that a new tapered liner can be inserted and driven home.

The wearing of the barrel owing to erosion is one of the most difficult problems the gun constructor has to face. Sir Andrew Noble (see "Some Modern Explosives," a paper read at the Royal Institution, 1900, also "Researches on Explosives," part iii., Phil. Trans. Roy. Soc.) has conclusively proved that the erosion is mainly dependent on the very high temperature to which the interior surface of the gun is raised and on the quantity of this heat. Both these factors are, for any particular explosive, determined by some function of the proportion of the weight of the charge to the extent of the exposed surface. The passage for the products of combustion gradually reduces from the maximum diameter of the chamber to the diameter of the bore. The highly heated gases therefore impinge more directly on that part of the bore which forms the seating for the shot and acts on it for the longest time, i.e., for the whole time the shot is in the gun. Consequently this part suffers most wear.

It may be assumed that the weights of the charges vary as the cube of the diameter of the bore, while the circumference of the bore varies directly as the calibre; now as the weight depends primarily on the weight of the charge in relation to the exposed surface at the shot seating it varies as the square of the calibre. It is evident that the allowable wear will vary as the calibre, so that the life of the gun or the number of rounds which can be fired is inversely proportionate to the calibre.

The heat of combustion and the time of burning of the explosive are factors in determining the amount of heat developed per unit of time, and thus influence the proportion of heat conducted away from the interior surface of the gun. The time of burning of the explosive depends on the size and form of the explosive and on the density of loading, while the heat of combustion depends on its composition and cannot be treated of here, but it may be stated generally that for equal weights Ballistite is more erosive than Cordite Mark I., and Cordite Mark II. All of these explosives contain a fairly large proportion of nitro-glycerin, and it is found that as the proportion of this ingredient is reduced the erosion also decreases, so that for pure nitro-cellulose powders it is less still. Unfortunately pure nitro-cellulose powders are not ballistically equal to the same weight of nitroglycerin powder; the advantage of the less erosive action is lost owing to the greater weight of pure nitro-cellulose explosive required to obtain the same ballistics.

The effect of erosion on large high-power guns is serious, for in a
12-in. gun after some 150 or fewer rounds are fired with a full charge, the barrel is worn so much as to need replacing. In the British service it is considered that the wear produced by firing sixteen half charges is equivalent to that of one full charge. The best practice for lighter guns and rounds with full charge which can be fired without replacing the barrel is considerably greater: while for low-velocity guns the number is higher still. In some guns this number appears abnormally high; in others of exactly similar rating it may be much lower or even nil at all.

The first effect of the powder gases on the steel is a very characteristic hardening of the surface of the entire bore; so much so that it is difficult to carry out any mechanical operation except grinding, upon a gun barrel after firing. While the explosive contained in the chamber of the gun burns fiercely, and as the projectile travels along the bore the highly heated gases follow. The surface of the bore near the chamber is naturally the most highly heated and for the longest time; here the loss of gas is greatest. But there is a consequence. A film of steel swells, which is a form of erosion, but this becomes greater, owing to the abstraction of heat by the bore. It is a noticeable fact that only where a decided movement of gas takes place is there any erosion; thus, towards the breech end of the chamber where no rush of gas occurs there is no perceptible erosion, even after many rounds have been fired. Again, at the muzzle end there is very little erosion, as here the gases are in contact with the air for only a few minutes, and the development of fissures is formed. With the old black and brown powders these fissures were a feature of the erosion, while with the new type smokeless powders the eroded surface is usually smooth, and it is of interest that there is some evidence to suggest that although fine cracks occur after a comparatively few rounds have been fired.

**FIELD ARTILLERY EQUIPMENTS**

**General Principles.—**A field gun may be considered as a machine for delivering shrapnel bullets and high-explosive shell at a given distant point. The power of the machine is limited by its weight, and this is limited by the load which a team of six horses is able to pull at a trot on the road and across open country. For under these conditions it is found that six is the maximum number of horses which can work the team at a working load, and that the maximum load for a gun-team is variously estimated by different nations, according to the size of the horses available and to the nature of the country in the probable theatre of war. Thus in England the field artillery load is fixed at 43 cwt. behind the traces; France, 41.5 cwt.; Germany 42.5 cwt.; and Japan (1903) 30 cwt. This load consists of the gun with carriage and shield, the limber with ammunition and entrenching tools, and the gunners with their kits and accoutrements. The weights may be variously distributed, subject to the condition that for ease of draught the weight on the gun wheels must not greatly exceed that on the limber wheels. It is still usual to carry two gunners on seats on the gun axle-tree, and two on the limber. But a Q.F. gun capable of firing 20 rounds a minute requires to be constantly accompanied by an ammunition wagon, and the modern tendency is to take advantage of this to carry some of the gunners on the wagon. Thus in the British field artillery two gunners are carried on the gun limber, two on the wagon limber, one on the wagon body and none on the gun. These five gunners, with the sergeant, called the No. 1, on his horse, make a full gun-detachment. Three wagons for each gun usually are provided, two of which, with the spare gunners and non-commissioned officers, are posted under cover at some distance behind the battery. Besides lightening the weight on the gun, the presence of the wagon allows the number of rounds in the limber to be reduced. The result of this redistribution of weights is that field artillery may now be equipped with a much heavier and more powerful gun than was formerly the case. A gun weighing 24 cwt. in action is about as heavy as a detachment of six can man-handle.

The power of a field gun is measured by its muzzle energy, which is proportional to the weight of the shell multiplied by the square of its velocity. The muzzle velocity varies in different equipments from 230 to 380 foot-tons. Details of the power, weight and dimensions of the guns of the principal military nations are given in the tables. A field gun of given weight and power may fire a heavy shell with a low velocity, or a light shell with a high velocity. High velocity is the gunner's ideal, for it implies a flat trajectory and a small angle of descent. The bullets when blown forward out of the shrapnel fly at first almost parallel to the surface of the ground, covering at medium ranges a depth of some 350 yards, as against half the distance for a low-velocity gun. Under modern tactical conditions a deep zone of shrapnel effect is most desirable. On the other hand, for a given power of gun, flatness of trajectory means a corresponding reduction in the weight of the shell; that is, in the number of shrapnel bullets discharged per minute. We have accordingly to compromise between high velocity and great shell power. Thus the British field gun fires an 18 lb. gun with muzzle velocity of 1790 ft. per second, while the French gun, which is practically of the same power, fires a 16 lb. shell with M.V. of 1740 f.s. Again, a shell of given weight may be fired either from a large-bore gun or from a small-bore gun; in the latter case the length of the shell will be proportionately increased. The small-bore gun is naturally the lighter of the two. But the longer the shell the thicker must its walls be, in order to break up or collapse in the gun. The shorter the shell, the higher is the percentage of useful weight, consisting of powder and bullets, which it contains. We must, therefore, compromise between these antagonistic conditions, and select the calibre which gives the maximum useful weight of projectiles for a given weight of ordnance. In practice it is found that a calibre of 3 in. is best suited to a shell weighing 15 lb; and that, starting with this ratio, the calibre should vary as the cube root of the weight of the shell.

As to rifling, the relative advantages of uniform and increasing twist are disputed. The British field guns are rifled with uniform twist, but the balance of European opinion is in favour of a twist increasing from 1 in turn in 50 calibres at the breech to 1 in 25 at the muzzle. Mathematically, the development of the groove is a parabola.

For field guns the favourite breech actions are the interrupted screw and the wedge. The latter is simpler, but affords a less powerful extractor for thrusting out the empty case and powder. This point is of importance, since cartridge cases hastily manufactured in war might not all be true to gauge. Modern guns have percussion locks, in which a striker impinges upon a cap in the base of the metallic cartridge. All Q.F. guns have repeating trip-locks. In these, when the firing-lever or lanyard is pulled, the striker is first drawn back and then released, allowing it to fly forward against the cap. The gun is usually fired by the gun-layer; it is found that he lays more steadily if he knows that the gun cannot go off till he is ready. A field gun has to be sighted (see SIGHTS) for laying (a) by direct vision (b) by clinometer and aiming-point (see ARTILLERY). The first purpose is served by the ordinary and telescopic sights; the second by the goniometric sight or the parallax sight. The

These weights do not include the gunners and kits.

1 In addition to the wagons with light ammunition column, now raised to 6½ per battery.

Doubtful figures are marked thus.*

2 Including four rounds with gun.
independent line of sight is an arrangement of sights and elevating gear found in many modern field guns, which divides between two gunners the work of aiming (called laying) the gun, and of giving it the elevation required to hit the target. In fig. 59 the gun is shown mounted on an intermediate carriage elevated and depressed by the screw A. The telescopic

From Bettelheim's Modern Guns and Gunnery.

**Fig. 59.** — Diagram illustrating the independent line of sight.

or ordinary sight is fixed to this carriage. The gun, in its cradle, is elevated and depressed by the screw B. To lay the gun, the layer works the laying screw A till the telescope points at the target; the gun also, if no elevation has been given, is then pointing straight at the target. To give the gun the elevation necessary for the range, the elevating number on the right of the gun now works the elevating screw B till the gun is sufficiently elevated, the amount given being shown in yards of range on a drum. The motion given to the gun does not disturb the intermediate carriage with the telescope attached to it, and the telescope still remains layed on the target. Once the sights are layed on the target, the elevation of the gun may be changed in a moment by a turn of the elevating wheel, without disturbing the laying. The layer does not have to concern himself about the elevation; he only has to keep his sights on the target while the other numbers continue the service of the gun. This device is especially valuable when firing at moving targets, when the range and the laying have to be altered simultaneously.

The same result may also be obtained by other mechanical devices without the use of the intermediate carriage. Thus the British field guns have a long elevating screw with the sight connected to its centre, the lower end passing through a nut at the side of the upper carriage, the upper end through a nut at the side of the cradle. Then, if the lower nut is turned by the elevating wheel, the screw, the sight and the gun will go up or down together; if the upper nut is turned, the screw, the sight and the gun will go up or down the screw without moving the sights.

Colonel Scott's "automatic" line of sight is an improvement on the ordinary gear in that the sight can be cross-levelled to eliminate the error due to difference of level of wheels. Krupp has a similar device in which the sight-screw is on the cradle so that it can be cross-levelled. The sight itself is connected to the telescopic sight, and is screwed out of its socket as the breech of the gun is depressed, so that the sights remain in the same place.

**Construction of the Gun.** Field guns are made of steel, usually containing a small percentage of nickel or chromium, or both, and having a tensile breaking strain of about 50 tons per square inch. In Austria, for facility of local manufacture, hard-drawn bronze is still used, although this is considerably heavier than steel. The Carriage (see Artillery, Plate I.). The first field guns used in war were supported by crossed stakes under the muzzle and anchored by a spike on the breech which penetrated into the ground. The next improvement was to mount the gun on a sleigh. This method is still used in Norway and in Canada. The next step was to mount the gun on a two-wheeled carriage, connected to a second two-wheeled carriage (the limber) by a flexible coupling. For centuries the gun-carriage was a fixed construction, recoiling on firing, and having to be run up by hand after each round. In 1865 spring-spade carriages were introduced. In these a spade attached to a helical spring was set under the carriage; on discharge the spade dug into the ground, compressing the sping as the carriage recoiled. The extension of the spring ran the gun up again without assistance from the gunners.

The British 15 pr. used in the South African War (1899–1902) had a spring spade carriage designed by Sir George Clarke. Similar equipments were introduced by several continental powers. The Japanese gun used in Manchuria (1904) had dragshoes attached by wire ropes passing round drums on the wheels to a strong spring in the trail. On recoil the wheels revolved backwards, compressing the spring; after recoil the pull of the spring on the wire ropes revolved the wheels forward and returned the gun to its former position. Italian recoil equipments were based on a very similar principle. All these semi-Q.F. equipments were open to the objection that the gunners had to stand clear of the shield every time the gun was fired. They have since been superseded by the recoil equipments.

The gun-carriage must be strong enough to carry the gun across country, and it must be so constructed as not to move when the gun is fired. If the gun-carriage were allowed to recoil to the rear on discharge, the gunners would have to stand clear on firing, allowing the protection of the shield to be of no use. The time entailed by running up and relaying the gun would render the fire slow. The requirement of steadiness of the carriage is met by allowing the gun itself to recoil on its carriage. Its motion is gradually absorbed by the cylinder (by the cold of recoil) which is returned to the firing position by helical springs, or, in the French, Spanish and Portuguese equipments, by compressed air. The carriage is held from recoiling by a spade fixed to the point of the trail (usually a plumb line or a string) and if it be abused during a recoil of 3 ft, the average overturning force is 2 tons; since the weight of the gun in action may not greatly exceed 1 ton, the trail must be so long as to give a leverage of at least two to one in favour of the steady force. If the gun recoils by the aid of springs, the energy may be promoted by four factors: (a) Increasing the weight of the gun and recoiling parts. This reduces the recoil-energy. (b) Increasing the length of recoil allowed. This increases the overturning force. (c) Making it impossible, either by reducing the height of the wheels, or by cranking the axle-tree downwards. This reduces the leverage of the overturning force. (d) Increasing the length of the trail. This increases the leverage of the steady force. It will be seen from Table A that the condition of steadiness is satisfied in the various Q.F. equipments by not very dissimilar combinations of the above factors.

**The Carriage** (see Field Artillery equipments.) The gun-carriage upon which the gun slides when it recoils. It also contains the buffer and running-up springs, which are fixed either above or below the gun. The latter method gives the stronger and simpler construction, and is favoured by all except the British. Great care has to be taken that the gun can be set lower on the carriage, which is an advantage as regards steadiness. A top-buffer cradle is of ring section, surrounding the gun; the gun is formed with ribs or guides extending for its whole length. On recoil the cradle and gun are split apart, which is opposed on horizontal trunnions to the intermediate carriage and carries the buffer and springs on top. This construction is shown in the illustration of the 18 pr. Q.F. gun (fig. 60, Plate III.).

In carriages having the buffer under the gun the cradle is a trough which rests on the top of intermediate carriage. It is provided on the upper edges fitted to guide-blocks on the gun. The cradle contains the buffer-cylinder, which is fixed to a horn projecting downwards from the breech of the gun, and recoils with it; the motion of recoil is absorbed by the buffer-cylinder, which is usually coiled round the buffer-cylinder, and, on recoil, are compressed between a shoulder on the front end of the cylinder and the rear plate of the cradle.

**Steadiness of Carriage.** In the gun-recoil equipment the constructional difficulty lies not in preventing the carriage from recoiling but in preventing the wheels from rising off the ground on the shock of discharge. The force of recoil of the gun, acting in the horizontal direction, tends to turn the carriage over backwards about the point of the trail, or, more correctly, about the centre of the spade. This force is resisted by the weight of the gun and carriage, which tends to keep the carriage on the ground. The recoil of the gun is a force which acts is that due to the distance of its line of motion above the centre of the spade; the leverage with which the steady force acts is that due to the horizontal distance of the centre of gravity of the gun and carriage from the contact point on the ground. If the recoil force is increased, the construction of the gun must be altered, either by reducing the height of the wheels, or by cranking the axle-tree downwards. This reduces the leverage of the overturning force. By increasing the length of the trail this increases the leverage of the steady force.

It will be seen from Table A that the condition of steadiness is satisfied in the various Q.F. equipments by not very dissimilar combinations of the above factors.

stability. To allow the liquid to flow past the piston, grooves (called ports) are formed in the sides of the cylinder, and by varying the depth of the grooves at different points the resistance can be adjusted as required.

In compressed-air equipments a separate piston is attached to the gun, working in a cylinder on the carriage connected with a reservoir of air at a pressure of about 300 lb to the square inch. This is much lighter than the springs, but the difficulty is experienced of the gun being thrown out of alignment due to it, although this difficulty is partly overcome by filling the cylinder with glycerine so that the air has direct access to the piston or the gland. In spring equipments the principal difficulty lies in providing a sufficient supply of recoil, and this is generally obtained by the use of springs. Thus if the spring column be 6 ft. long, and the gun recoils 4 ft. the springs are compressed into a space of 14 ft., or a quarter of their working length. This treatment is likely to break the springs, and makes it necessary to use the most powerful spring that can be used. But in England the telescopic spring-cased patented by the Elswick Ordnance Company is preferred. Suppose that the spring-columns before firing are each 4 ft. long; then if the telescopic gear be pulled out for a distance of 4 ft. before recoil, each spring column will be compressed to a length of 1 ft., and if the telescopic case springs are used by some firms, as Cockrell of Sering (Liège). They are open to the objection that if a spring breaks the gun is for the time being rendered useless, which is not the case with compressed air.

The intermediate carriage is used chiefly in equipments with buffer above the gun; it serves as a means of connecting the cradle to the lower carriage. When the spade is fixed in the ground it is important that the access of air to the cradle should be blocked; aim, the intermediate carriage is therefore pivoted so that it can traverse laterally about 3 degrees each way. Instead of using an intermediate cradle the direction may be given to the gun by sliding the carriage sideways along the axle in another plane, the point of the trail, which is fixed by the spade. This system is used in guns of French manufacture and in the 1902 Russian gun. It is simple in action, but requires the shield to be cut away on either side of the cradle to allow for the extreme traverse.

The trail is either a drawn steel tube, of circular section as in the 18 pr., or of closed U section as in the Ehrhardt carriages, or else a box trail built up of sheet steel. In the Krupp equipments the trail is bent downwards to give a greater range of elevation to the gun.

Elevating Gear, in order to save space, is usually of the telescopic screw pattern, in which one screw is inside the other so that the two pack into half the length of a single screw. The spade is of the shape shown in the illustration of the 18 pr. Q.F. gun. For equipments which may have to be used on rock, such as the Swiss gun, the spade is made to fold upwards when desired. The axle and its connections with the carriage are made equal to the original carriage and wheels. The wheels are of wood, with naves of stampled steel. Steel wheels have been tried but are less elastic than wood and have been found unsuitable. England and the United States use 4 ft. 8 in. wheels. The recognition of the 18-pr. French gun is by the colour of the wheels, also the wheels of the shields.

The shield is made of hard steel, from o-12 to 0-256 in. thick. The size and thickness of the shield are limited by considerations of weight. Thus if 150 lb of weight be available this will provide a shield and a traversing hand-spike weighing the same. A shield weighs about a drif rifle bullets at distances over 600 yds., and against shrapnel bullets at all distances. The present tendency, since the introduction of the French D bullet and German S bullet (see Ammunition, Ballistic), is to make shields thicker than this, 5 mm. or 0-2 in. being the usual thickness.

Recent Developments of the Q.F. Gun-Carriage.—The principle of "differential" recoil gear is as follows: Suppose an ordinary Q.F. field gun held in the recoil position by a catch, loaded, released and allowed to recoil, and that the reciprocal values for each section of the recoil valve in the buffer relieves the gun of any resistance to running-up. While in rapid motion forward the gun is fired by a trigger which catches the firing lever. The gun then returns to the recoil position and is again fired. The recoil is reduced by the amount of the forward velocity previously imparted to the gun. Thus if the ordinary recoil-velocity of a Q.F. gun be 35 ft., and if it be fired while running up at a velocity of 10 ft., the recoil will be reduced to the amount of 10 ft. instead of 35. Since the recoil-energy is proportional to the weight of the gun multiplied by the square of the recoil-velocity, the recoil-energy is reduced in the proportion of 900 to 400, or roughly by one-half. The effect is a considerable saving in weight, and it is also possible to make the gun and carriage lighter for the same power, or to obtain greater economy for the same weight. This increase of efficiency is due to the fact that the whole of the recoil-energy is not, as in ordinary Q.F. guns, absorbed by the friction in the buffer, but that part of it is stored up and used to counteract the recoil of the next round. If the hydraulic buffer be dispensed with, and the whole of the recoil taken on the springs or compressed air gear, the over-turning stress is reduced to one-fourth of its normal amount. One practical difficulty in the way of applying the differential system to field guns lies in the vibration and slight lateral motion of the carriage during running-up. Since this motion takes place after laying, it is not unlikely to cause inaccuracy. The only equipment on this principle as yet in use is the French 907. Three guns are referred to below.

Semi-automatic Q.F. field and mountain guns are made by the Krupp company. The equipments of these equipments the breech is open by tripping gear during the run-up, and the cartridge case is ejected. When the gun is reloaded the action of introducing the cartridge releases the breech-block, which is then automatically closed. This is a breech of the semi-automatic type. The principal advantage of the semi-automatic system lies not in the increased rate of fire but in the fact that three guns are sufficient to carry out the service of the gun. The importance of mountain equipments, where the size of the shield is limited.

The introduction of airships into military operations has produced a new type of anti-airship gun, which differs from the ordinary field gun in almost every respect. The equipments presents special problems. High elevation, even higher than the howitzer's, may have to be given, and, unlike the howitzer, the airship gun must be a high-power weapon, both ranging power and flatness of trajectory. The airship must be able to resist a tremendous amount of recoil, to be able to carry on firing even if the cartridge case is blown out of the breech, and to be able to withstand the extreme shock of landing on the water. The main advantage of the semi-automatic system lies not in the increased rate of fire but in the fact that three guns are sufficient to carry out the service of the gun. The importance of mountain equipments, where the size of the shield is limited.

The British 18-pr. Q.F. Field Gun (1905) (see Plate III., figs. 60 and 61; also Artillery, Plate 11.)—Taking fig. 60 from the top, we see the buffer below the cradle, which, as explained in the text, is 4½ ft. long. The cradle, of brass, surrounds the gun, and is pivoted on horizontal trunnions on the upper carriage. The gun recoils in the cradle on the guide ribs, which extend for its whole length. The upper carriage is pivoted vertically on the trail and is traversed by the handle seen below the breech. The long elevating screw is formed as a telescopic screw at its lower end to avoid any danger of disengagement, and which in turn, but the nut at bottom raises the gun, screw and sights for laying on the breech at top raises and lowers the gun alone for giving elevation. The tubular trail supports the barrel-arms, which also carry the seats for the sights, and a traversing hand-spike are seen at the end of the trail. The telescopic case is the shield of the left of the gun. The shield is curved well back to give as much protection as possible to the detachment. The larger portion of the shield is used for traversing the gun for travelling.

The French Q.F. Field Gun (1907) (see Plate 12; also Artillery, Plate 11.)—This is a powerful gun, of unusual length, namely 36 calibres. The breech mechanism is of the eccentric screw type (see Part I. of this article). The gun has compressed-air running-up, and the trail is traversed by a trail spade and two brake-blocks which are arranged so as to go under the wheels, forming dragshoes, on firing. This method of counter-acting causes some delay in coming into action and considerable delay in being readied for action. The, however, are carried forward in a cylindrical case, and they have a Practically instantaneous sight with independent line of sight. The body of the ammunition wagon is tilted alongside the gun, and, with its armoured bottom and steel doors, forms a good protection for the gunners supplying it.

The German Q.F. Field Gun (1906) (fig. 63,)—This is the 1896 gun remounted on a Q.F. carriage. It is not a powerful gun, the ballistics being the same as those of the British 15-pr. B.L. of 1893. It has a single-motion traversing hand-spike, which is traversed by a trail spade with buffer and springs under the gun; the cradle traverses on a vertical pivot set in a traversing bed which turns about the axletree. The gun has an arc sight with prismatic telescope and a clinometer movement, and, being of greater power, it is a more effective mark. It has not the independent line of sight. The shield is in three pieces, the top flap folding down for travelling. The carriage stands perfectly steady on discharge.

The Russian Q.F. Field Gun (1907) is intended as an improvement on the French gun, being of even greater power. Springs are used for running-up instead of compressed air. To ensure steadiness the gun is kept very low on the carriage; this is effected by the use of
a cranked axletree. The gun has not the independent line of sight, but has a panopoma sight. It traverses on the axletree.

The Danish Q.F. Field Gun (fig. 64, Plate IV.) is a good example of the heavier or more powerful type of Krupp field gun. The gun may be seen supported on the cradle, which contains the hydraulic buffer and running-up springs. The wedge breech-block is open.

The arc sight with panorama telescope is seen behind the shield, which is curved backwards for better protection. The seats for the gunners who lay and attend to the breech are on either side of the trail. At the point of the trail are the spade, the traversing lever and the trail eye by which the gun is limbered up.

The American Q.F. Field Gun.—This is an example of the Ehrhardt type of gun. It is considerably more powerful than the field guns adopted by most European powers. Steadiness is ensured by making the trail 103 ft. long, or 1 ft. longer than the Krupp trail. The construction is otherwise very similar, which is the Krupp gun, shown in fig. 64, Plate IV. Four rounds are carried in tubes on the carriage.

Other Q.F. Equiments.—These closely resemble the standard types of their makers, as given in the above table of field guns. The Swiss and Dutch guns are light Krupps; the Spanish and Portuguese guns, by Schneider of Creusot, are improved and lighter models of the French gun.

The new Italian gun is a medium Krupp. The Austrian gun is similar to the American (Ehrhardt) but the gun itself is of bronze.

Horse Artillery Guns.—A horse artillery gun must be mobile enough to accompany cavalry. This is secured partly by the adoption of a light type of gun, partly by carrying the gunners on horseback instead of on the carriage. It is considered that the weight behind the team should not exceed 30 cwt. The Germans have declined to introduce a special type of light gun, as they

object to the complication entailed by the supply of two natures of ammunition on the battlefield. The H.A. guns of other nations are merely lighter and less powerful editions of their field guns.

The Q.F. Field Howitzer.—A field howitzer is a gun capable of throwing a shell weighing 35 to 45 lb at high angles of elevation, and light enough to manœuvre at a trot across open country. The permissible weight of the equipment is but slightly greater than that of a field gun. The object of the howitzer is to throw a heavy shell with an angle of descent not less than 25°, so as to destroy overhead cover with high-explosive shell, and to search entrenchments and reach gunners behind their gun-shields with shrapnel. Effect is obtained, not by the striking velocity of the shell, but by the amount of its high-explosive burster, or, in the case of shrapnel fire, by the use of a large driving charge in the base of the shell which gives the necessary forward and downward velocity to the bullets.

Since the muzzle energy of a howitzer is limited by the weight of the equipment, the heavy shell can only be fired with a low velocity, usually not exceeding 1000 ft. per second. And in order to secure a steep angle of descent at short ranges this velocity is still further reduced by using half and quarter charges.

The construction of the howitzer is much the same as that of a gun. The calibre is usually between 4-3 and 4-7 in., and the length does not much exceed 12 calibres. Case ammunition is used, and the breech action is similar to that of a Q.F. gun. Howitzers are usually provided with shields in order to enable them to come into

Redrawn from Bethell's Modern Guns and Guimnery.

Fig. 63.—The German Q.F. Gun. C. 96. n./A. (1906).

Fig. 65.—Rumanian (Krupp) Quick-Firing Field Gun.
HEAVY FIELD AND SIEGE

ORDNANCE

action in the open when necessary. At short ranges, with full charge, they make very powerful guns.

Construction of the Carriage.—The gun-recoil system is used as in a gun equipment. There is however one important difference. If the recoil allowed be sufficient to keep the carriage steady at high elevations, then when fired at an elevation of 45° the breech will strike the ground. This may be to some extent avoided by placing the trunnions of the cradle which supports the howitzer at the extreme rear end, so that when elevated the breech of the howitzer is not brought any nearer the ground (Krupp). One objection to this is that the forward preponderance of the howitzer has to be balanced by a spring to enable it to be elevated.

A second carriage is also provided for use as a controlled recoil. The buffer-liquid, on recoil, has to pass through holes in the piston. The access of the buffer-liquid to these holes is controlled by a disk valve rotated by tilted screws in the cylinder. By connecting the piston-rod to the carriage trunnions and rolling the piston, and simultaneously raising the area of the holes exposed by the disk valve can be decreased at high elevations so as to shorten the recoil. This is known as the Vavasseur-Ehrhardt control valve. Messrs. Cockerill use a channel through which the power obtained on recoil, which, in practice, is a stopcock connected to the left trunnion when the howitzer is elevated. The running-up springs require to be strong in order to lift the weight of the howitzer at 45° elevation. In most equipments twin columns of springs are used.

The Ehrhardt Q.F. Field Howitzer, fig. 67 (Plate IV.), may be taken as a type of the light field howitzer with controlled recoil, as opposed to the Krupp pattern with rear trunnions and constant long recoil. The howitzer is represented immediately after firing, before it has run up. The recoil is automatically shortened so that when fired at this high elevation the breech, before it can strike the ground, is brought by the piston far enough away from the carriage to prevent the howitzer from striking the ground. The cartridge is 4.7 in.: the howitzer fires a 46 lb. shell with M.V. 995 ft. per sec., and weighs 25 cwt. in action with shield.

The Q.F. Mountain Gun.—A mountain gun has the same tactical duties to fulfill as a field gun. It is merely a field gun sufficiently mobile for mountain transport. Its weight and dimensions are restricted by the following considerations: (1) The whole equipment has to be carried up the mountain by pack animals. (2) The average load for a battery mule is about 280 lb., including 65 lb. of saddle and equipment. A few specially selected gun-mules can carry about 40 lb. more, or 320 lb. In Spain and Italy, where exceptionally fine mules are reared, the average load is taken by the mule to be about 375 lb. (3) The loads must be short, the length being limited by that of the neck of a mule. If possible no part of the equipment should be more than 4 ft. 6 in. long. (4) The equipment must, therefore, be subdivided into sections which can be carried on a mule, and held in the first truck within one minute. Other nations mostly divide the equipment into four parts only, and use rather heavier loads than is in England considered consistent with activity on a hillside. (5) Mountain guns usually provided with shafts to enable them to be drawn instead of being carried when travelling along a road.

On a 5-mile basis the total weight of gun and carriage carried amounts to 103 cwt. or more than half the weight of a field gun. But the gun and carriage, and not the horses, are the chief load and it is therefore limited by the weight of the gun itself, which is restricted by the carrying power of the transport animals. In B.L. mountain equipment

ments this difficulty has been got over by carrying the gun in two parts, which are screwed together on coming into action.

In the British service the 7 pr. R.M.L. of 400 lb., the original "screw gun," was superseded in 1900 by the 10 pr. B.L., also in two pieces. A quick-firing mountain gun has since been introduced (1907).

In modern mountain equipments, such as the Schneider-Danglis howitzer adopted by Russia, the gun is not divided across the bore but is lightened for transport by subdividing the cradle and the recoil-block, which are carried separately. These guns fire a shell of 14.3 lb. with M.V. of 1100 ft.

When the gun is in one piece, the equipment naturally divides itself into four parts, namely the gun, cradle, trail and axle-tree and wheels. When a long jointed trail is used, as in the Krupp Q.F. mountain equipment, the point of the trail is carried with the wheels, which form a light load. In addition to this the folding shield with ammunition box is not needed, however, before brought up till after the gun has opened fire.

Since the length of a mountain gun in one piece may not exceed 4 ft. 6 in., the calibre has to be comparatively large to get the necessary power, and is usually 75 mm. or 3 in. The weight may not exceed 255 lb. A short breech action such as the swinging block or the eccentric screw is preferred. The sights must be of simple pattern; the independent line of sight is too complicated for mountain work. But it is most desirable that the sight-socket should be capable of being cross-levelled to eliminate the error introduced by difference of level of wheels. Except in the French gun, the recoil gear and running-up springs are similar to those used in Q.F. field equipments. In the French mountain equipment the gun does not slide directly on the cradle guides, but is supported by a steel forging called a sleigh, which forms a sliding cover to the cradle and protects the guides. On recoiling into action, the gun is dropped into the sleigh and secured by a keyed lug. The trail of a Q.F. mountain gun has to be from 6 ft. to 7 ft. long, to keep the gun steady. It is either carried in two pieces (Krupp) or hinged and folded (Ehrhardt). The spade is similar to that used with field guns. The wheels are of wood, about 3 ft. in diameter. The elevating gear is a plain screw. The gun and cradle traverse on a vertical pivot at 3 degrees each way. A shield high enough to protect the gunners kneeling weighs up to 1 cwt., and is carried in two pieces.

The Krupp mountain gun, fig. 68 (Plate IV.), may be taken as an example of ordinary practice. The gun is seen mounted on the sleigh, which slides to the rear on the cradle when the gun recoils. The cradle is pivoted on a saddle mounted on horizontal trunnions between the trail brackets; the rearward extension of the saddle forms the traversing bed and is supported by the elevating screw and pin, the foresight and arc are attached to the cradle. Near the middle of the 7 ft. trail are seen the seats for the laying and loading numbers. The trail is divided immediately in front of the seats, and is 425 lb. in. The gun fires a shell weighing 11 lb. to 10 oz. with a muzzle velocity of 292 ft.

The French 1907 mountain gun differs markedly from other types in that, the carriage, which is imported with different recoil gear as described above. There is no hydraulic buffer, and the whole of the recoil-energy is absorbed by the springs. The gun is held in the recoil position by a catch, and when loaded and released it is fired automatically by a trigger on the cradle. The calibre is 2-65 in., and the shell weighs 11 lb. to 10 oz.

III. HEAVY FIELD AND SIEGE EQUIPMENTS

Heavy Field Batteries.—Since the days of Gujrat and Inkermann the value of heavy metal in the field has been recognized, at all events in theory, but it was mainly due to the South African war that "heavy" batteries have become a component part of modern armies. Guns heavier than field guns have formed part of the equipment of the Indian army for many years.

---

FIG. 66.—Wagon Body, Rumanian (Krupp) Quick-firing Field Gun.
but they have existed for a specific purpose, and ordnance originally designed for quite other functions has, from the exigencies of war, been occasionally utilized in the field, as was the case in South Africa and Manchuria, but the heavy field battery as we know it to-day is a new military product. Its rôle is an extensive one, as it embraces many of the functions of ordinary field guns as well as some of those usually attributed to light siege pieces. In the heavy field armaments of the Powers as they stand at the present time will be found guns, howitzers and mortars, and projectiles that vary from 50 lb to more than five times that weight, and no boundary line can be assigned which will separate these field equipments from those of the light units of a siege train. It will be convenient to consider in turn the three nature of ordnance (guns, howitzers and mortars) employed and to quote some typical instances of each kind.

The United States 60 pr. Gun.—This gun and its equipment are of modern type (1904). Its general appearance is shown in fig. 69 and Plate V. The calibre is 4.7", the charge 24 lb.

Of smokeless powder and the muzzle velocity developed is 1700 f.s. Fixed ammunition is employed, and with an elevation of 15° the range is 7600 yds. The weight of the equipment limbered up is given as 714 cwt. It is known as a siege gun.

In its general aspect the carriage resembles a field carriage, but of stronger type, with a special arrangement of cradle.

In fig. 71 two sections are given; the cradle, it will be seen, consists of three cylinders (seen in section in the upper figure) which are bound together by broad steel bands; the two outer cylinders carry rails upon which the gun slides in recoil. The centre cylinder contains the hydraulic gear for checking recoil, the two outer contain the running-up springs. These springs are arranged in three concentric columns, the front end of each outer column being connected to the rear end of the next inner column by a steel tube, flanged outwardly at the front end and inwardly at the rear end. A rod carrying a head which acts on the inner coil only passes through the centre of the cylinder and is fixed to a yoke that is connected with a lug at the breech of the gun. The flanged tubes thus convey the pressure from the innermost coil to the next outer coil and finally to the cradle, so that in each cylinder the springs work in tandem and have a long stroke with short assembled length. It is thus seen the recoil takes place partially on the carriage and only a portion of the energy remains to tend to cause movement in the mounting.

The cradle is supported by trunnions in the casting y, which is itself seated in the casting b, which forms a bearing for it. This bearing is mounted between the front ends of the truss brackets, its rear end embracing the hollow axle z. Attached to the rear side of y is the traversing bracket s, which extends to the rear under the axle and forms a support for the traversing shaft f and for the elevating mechanism.

For travelling (Plate V., fig. 69) the gun is withdrawn to the rear and the breech is attached to a holding-down arrangement about the middle of the trail. A space is hinged at the point of the trail.

The British 60 pr. Gun.—This is known as a heavy battery gun; its calibre is 5", its length 32 calibres, its weight 59 cwt.; its charge is 9½ lb of cordite, its muzzle velocity 2050 f.s. and its effective shrapnel range 10,000 yds. The weight behind the team is 106 cwt., 3 qrs.

The German 10 cm. Gun is called a heavy battery gun; its calibre is 4", its effective shrapnel range is 7570 yds., but common shell can be used up to 11,000 yds. The organization is a six-gun battery, but a platform has always to be used.

A howitzer is a comparatively light piece that fires a comparatively heavy shell with a comparatively low muzzle velocity, and changes in range are effected sometimes by alteration of charge as well as of elevation. On the continent of Europe howitzers are more popular than guns for heavy field batteries and light siege units.

The French 15 cm. (Rimailho) Howitzer.—This piece is at the present time very popular in France, where, in 1907, 120 batteries of the field army were said to be armed with it. It came into being from the conversion of an old pattern siege howitzer and its adaptation to a new form of carriage, according to the plans of Commandant Rimailho. The gun (canon de 155 R) is a short piece, made of steel, with a calibre of 6-1"; the shell weighs about 94 lb and has an effective range of 7000 yds. The breech opens automatically after each round and a rapidity of fire of from 4 to 5 rounds a minute is claimed. The howitzer is supported on two trunnions near its rear end so that the weight pivots about a point near the breech, with the result that the latter remains nearly stationary above the ground level at all angles of elevation; space is thus left for recoil, which is checked by a buffer, the construction of which is a secret; running-out springs are provided to return the gun to the firing position. The piece recoils in a cradle to which is attached the elevation scale, but the elevating gear is independent of the carriage proper; the line of sight is also independent. The howitzer has a special transporting carriage, but it can be placed on its firing carriage, it is said, in two minutes. The weight behind the teams is in each case about 47 cwt. (Chamfires) per howitzer would be provided.

The German 15 cm. Howitzer.—The Germans also possess a 15 cm.howitzer of modern type; its rate of fire is 2 to 3 rounds a minute; its shell is 8½ lb in weight and the weight behind the teams is about 53 cwt.

The British 6" L.H. Howitzer.—This piece is made of steel, it weighs 50 cwt., its shell weighs 122 lb and has an effective range of 7000 yds. The weight behind the teams is in each case about 47 cwt. Fig. 72 shows the howitzer and cradle A mounted on the travelling carriage, from which it can be fired up to an angle of 35°; in fig. 73 the wheels have been removed, the trail B has been lowered on to the pivot plate C and secured to a pivot plug screwed into the plate; to the trail is fitted the top carriage D, and when the howitzer and cradle are thus mounted 70° elevation can be given. The howitzer recoils through the cradle, in which are two hydraulic buffers side by side, fig. 74, whose piston rods E are attached to the howitzer so that the recoil of the latter draws the pistons J to the rear. Consider now, in fig. 74, the right buffer only; forged in one piece with the piston rod is a tail rod F of larger diameter than the piston rod, and in the front of the cylinder is an annular bronze casting G, called a floating piston, which bears against the rear of the springs. On discharge, the howitzer slides along the cradle to the rear, the piston rod E is drawn out of the cylinder and the tail rod F is drawn in, and from its larger diameter causes a pressure of oil against the floating piston G, which slides forward and compresses the springs which are prevented moving by the rods H. The action is the same in each buffer. After recoil the springs expand and return the howitzer into the firing position.
The floating tapers are placed inside the cradle to prevent movements in the running out action. The lower gear, which can be placed on the right side of either the carriage or the top carriage, actuates the cradle, bolted to the top side of the cradle. When the gun is fired on wheels (fig. 72), an anchorage bolt M, attached to the platform, checks the recoil, while the springs, with which it is provided cause the carriage to return to its position.

The United States 6" Howitzer.—This is a modern American gun. The cartridge is a short piece, 13 calibres long; it fires a 120-lb shell with a muzzle velocity of 900 f.s. It has an extreme elevation of 45° and an effective range of 7000 yds. The weight behind the team is 701 cwt. The carriage is of peculiar construction (fig. 75). The howitzer is supported under its cradle, which is carried on traverses seated in the top carriage. The cradle consists of three cylinders generally similar in arrangement and in those described for the 47 1/2" 60 pr. gun: the howitzer is made in a single forging and carries a lug on its breech end for the attachment of the recoil piston rod and the yoke for the rods of the spring cylinders; flanged rails are formed on its upper surface, which support it on its cradle. The top carriage rests on a framework called a "pintle bearing." Flanges in the former engage under the latch; the pintle bearing is revolved to the front part of the trail brackets, and forms a turn-table upon which the top carriage is supported and so that the cradle can be moved on the cradle traverses on either side.

This movement of traverse is effected by a shaft and worm: the former is supported, in a fixture attached to the left trail bracket, and the latter works in a nut pivoted to the top carriage. Elevation is effected by a forging called the rocker. The rear part of the latter is U-shaped and passed under the gun, being attached to the cradle by a pivoted hook k. From either side of the U arms extend which embrace the cradle trunnions between the cradle and the cheeks of the top carriage so that the rocker can rotate about the cradle trunnions. The elevating gear is supported in lug on the lower side of the top carriage, while the upper end of the elevator screw is attached to the top bracket of the rocker. The rocker thus moves in elevation in the top carriage and gives elevation to the cradle, and therefore to the gun, by means of the pivoted hook above referred to.

The brackets of the trail extend separately to the rear, sufficiently providing for free movements of recoil at any elevation; they are then joined by transoms and top and bottom plates and terminate in a detachable spade which is secured to the top of the trail in travelling. The axle is of special shape to admit of the movements of the cradle; it is lower in the middle than at the sides and is made in three parts, held together by shrinkage in cylinders formed in the sides of the parts of the axle.

A peculiarity of this carriage is that recoil is automatically shortened as elevation increases. Thus the length of recoil is 50° at angles of firing from −5° to 0°, from 0° to 25° the 50° is gradually reduced to 28°, which is the maximum elevation. This is effected as follows: Four apertures are made in the recoil cylinder, and two longitudinal throttling grooves are placed in the walls of the cylinder. All apertures being open and deepest part of grooves in use would correspond to a 50° recoil. A rotating disk with apertures similar and similarly placed to those on the piston is carried by the piston rod and rests against the front of the piston, and is actuated by eccentric, so as to project into the slots cut in the walls of the recoil cylinder. The latter is mounted so as to be capable of rotation in the cradle, and its outer surface carries teeth which engage with similar teeth in a ring surrounding the upper spring cylinder. When the elevation is between 0° and 25° these latter teeth engage in special gear which is seated in the hollow trunnion of the cradle and is attached to the right cheek of the top carriage. The buffer conditions are thus made to correspond with the elevation.

The mortar is a short piece of ordnance that is always fired from a bed. Changes in range are usually effected by varying the charge.

United States 3½" Mortar.—This piece is not modern; the piece intended for vertical fire against masts of entrenchments; the mortar weighs 25 lb, and its bed, which is made in a single casting of steel, 300 lb. The latter rests in action on a wooden platform, which is lowered when the work is finished and placed on wheels to be drawn by eight horses.

The German 3½" Mortar.—This piece is perhaps the heaviest field equipment existing. The mortar in action weighs about 4½ tons; it has to be transported in a special vehicle and can only be fired from the ground. Four hours are required for bringing it into action. Two platform wagons are attached to each mortar, weighing respectively 2½ and 4½ tons. The equipment can be moved at a walk on good roads, but two companies of infantry are always attached for haulage in case of need. A battery consists of four mortars, and 1060 tons are required for firing.

A high explosive charge consists of 400 grms. of a new composition made by Messrs. Krupp, as shown in Plate VI., figs. 76 and 77. It is a lifting charge for an 8½" mortar, seated on the long range, which till now has not been provided with a carrying carriage without a platform. This equipment weighs about 5 tons in action.

All the foregoing equipments may be considered mobile; that is to say, the batteries in which they are organized are self-contained, can move from place to place without external assistance, and may be employed on either field or siege duties. Their use may be summed up as follows: The first object of the heavy artillery is to assist the infantry in entrenching the barrier and other frontier fortifications of a permanent nature in order to enable the army to penetrate into the enemy's country. After this has been done, a small portion of this artillery will be employed in connexion with the siege of fortified places, and a considerable portion, will accompany the advance of the field army.

Heavy Siege Units.—When a serious siege has to be undertaken it is necessary to organize one or more siege trains in addition to the troops of the field army. Both heavy and light siege units enter into the composition of a siege train. As to the armament of the latter, we have said that it is not exactly distinguishable from that of heavy field batteries, and it has already been described. That of the former is less definite. Heavy siege units are seldom mobile in the sense that light siege units are: the ordnance comprising the former has usually to be transported by some special means; thus it might be conveyed by ordinary rail or ship to some place from which special siege railways would admit of its conveyance to its place in battery, and probably very great variety of calibre and mounting would exist. For example, during the siege of Sebastopol a civil engineer, Robert Mallet (1802—1881), designed a 36" mortar; it did not, however, reach the seat of war; and in 1904 the Japanese made use of their 11½" coast howitzers at Port Arthur. At the siege manœuvre at France in 1906 the heavy siege units were provided by their 6½" guns and their 10½" howitzers. The official British pieces are a 6" gun and a 9¼" howitzer. Generally speaking, whereas the most suitable armament of the light units can as a rule be foreseen; that of the heavy would depend very much on circumstances.
ORDNANCE

The French 10-7" Howitzer.—As a typical piece the 10-7" howitzer may be taken, which the French transported by special horse draught, as it was found too heavy for the type of siege railway made use of at the mock siege of Langres in 1907. Its total equipment weighs 22 tons and it is transported in four components, namely, the piece, the carriage, the slide and the platform. A battery of six pieces would thus require, exclusive of ammunition hydraulic buffer is attached to the front of the slide and also to the bed.

The fighting units of siege artillery in the British service are companies and brigades; each company would be armed with from 4 to 6 light siege pieces or from 2 to 4 heavy pieces. A company is usually a major's command. Three such companies would form a siege brigade under a lieutenant-colonel. If a siege train of any magnitude were organized it might be necessary to combine two or more brigades into a division under a colonel or brigadier. In the French service each siege train consists of three divisions. A division is divided into groups and comprises some 30 pieces of ordnance, heavy and light.

IV. GARRISON MOUNTINGS

The armament of modern coastal fronts consists of (a) heavy B.L. guns, 9" and upwards; (b) medium guns, 4" and upwards, and (c) light Q.F. guns; all these being for direct fire; and (d) guns, howitzers or mortars of various calibres for high angle fire. Typical guns of type (a) are the Krupp 12" gun and the British 9-2 B.L. gun. The Krupp 12" gun is built up of crucible cast nickel steel, not wire wound. It is 45 calibres long and has the Krupp wedge-shaped breech-closing apparatus. It is fitted with a repeating trip lock. The carriage is a metallic case containing a charge of 290 lb of tubular powder. The projectiles are of two weights, 770 lb and 980 lb, and the respective muzzle velocities are 3025 f.s. and 2700 f.s. The British 9-2 B.L. gun is of wire-wound construction and is over 48 calibres long. It has the asbestos pad and Welin screw system of obturation, and its charge of 103 lb of cordite, contained in a cartridge of silk cloth, fires a 380 lb projectile with a muzzle velocity of 2643 f.s. A typical gun of class (b) is the British 6" mark VII. It is similar in construction and breech mechanism to the last-named and fires a 100 lb projectile with a charge of 23 lb of cordite, giving a muzzle velocity of 2493 f.s. A typical gun of class (c) is the British 12 pr. Q.F.; its weight is 12 cwt., it is made of steel, is 10-3 calibres long, and with a cordite charge of 1 lb 15 oz, it fires a projectile 12½ lb in weight with a muzzle velocity of 2107 f.s. and a possible rate of 15 aimed rounds a minute. A typical piece of class (d) is the 11" Krupp howitzer. It is 12 calibres long, has a charge of 28½ lb smokeless powder and fires steel shell weighing 470 lb or 750 lb. It is provided with a shrapnel shell of the former weight which contains 1850 bullets.

The methods of mounting of coast ordnance are many; space only permits of referring to certain typical arrangements.

1. The Moncrieff Principle.—The disappearing carriage originated, at all events in England, with Colonel Sir A. Moncrieff, who, about 1864, proposed to utilize the energy of recoil to bring a gun into a protected position and at the same time to store up sufficient energy to raise it to a firing position when loading was completed. To effect this a heavy counterweight was so adjusted that its tendency was to raise the gun; when the latter was fired, it raised the counterweight and a ratchet and pawl followed the action up: when the pawl was released the counterweight brought the gun back to the firing position; this application of the principle had many drawbacks, and never had any success with guns over 7 tons in weight. It not until Moncrieff invented the hydropneumatic appliances that any real progress was made. In 1888 was introduced into the British service the first of a large group of disappearing mountings for guns of types (a) and (b), where the energy of recoil was absorbed chiefly by forcing a large volume of liquid through a narrow opening or recoil valve, and also by further compressing a large volume of already highly compressed air; when recoil was completed the recoil valve closed and the air was retained at very high pressure: the energy thus stored up returned the gun to the firing position. The action will be understood from the following example.

The British 6" B.L. Gun on H.P. Mounting, Mark IV.—Fig. 78 shows a general view of the mounting; fig. 79 is a vertical and
fig. 80 a transverse section through the recoil cylinder. The gun trunnions (fig. 78) are supported by the two arms of the elevator A, which is pivoted to the front of the lower carriage at B. The breech is supported by the two elevating bars C whose lower ends are attached to the elevating arcs D. These arcs are worked by the elevating gear actuated by the hand-wheel E. The arcs are struck with the bars C as radii, their centres being points at the upper end of the bars when the gun is in the loading position. Elevation can thus be given to the gun whilst it is being loaded. The lower carriage rests on a ring of live rollers G, which are free to traverse round on a circular racer H, motion being given by traversing gear actuated by the hand-wheel I. Supported by vertical stanchions attached to the lower carriage is a horizontal circular shield J through which the gun rises to the firing position. The manganese bronze ram F which is attached to the elevators A by the cross-head L is forced on recoil into the central chamber of the recoil cylinder (see fig. 79), which is supported by trunnions M resting in the brackets of the lower carriage. There are ten chambers N (figs. 79 and 80), all of which are connected at the bottom with the recoil valve chamber O, and consequently with each other. Nine of these contain liquid in their lower portions and highly compressed air above, and are connected at the top by a channel P to equalize the pressure in each chamber. The tenth chamber N', which is situated lowest in the cylinder, contains liquid alone and has at its upper end the raising valve Q. On recoil the liquid in the central chamber is forced by the ram through the recoil valve R into the outer chambers N, thus further compressing the air. As R is a non-return valve the air is maintained in this highly compressed state during loading. The gun is raised by pushing the lever S (fig. 78) to the front which actuates the rack T (fig. 79), thus opening Q, which allows the air in the nine chambers to force liquid from the tenth chamber N' into the centre ram chamber, lifting the ram. U is a pump (fig. 79) by which the gas can be pumped down at drill. The liquid expelled in the buffer is a mixture of methylated spirits, mineral oil, distilled water and carbonate of soda, and its aeration, due to the churning it receives on recoil, is a serious drawback to this class of mounting. From a 6" B.L. gun mounted in this fashion somewhat more than one aimed round a minute can be obtained; from a 9.2" B.L. about four such rounds in five minutes.

The foregoing description is now, however, principally interesting as showing an ingenious application of mechanical principles for military purposes. Mountings of this type are being gradually withdrawn from the British service.

The Buffington-Crozier Principle.—In the United States a type of disappearing carriage known as the Buffington-Crozier (fig. 81) is used. Here, as in the earlier types of Moncrieff carriage, a counterweight is employed, but the energy of recoil is partly absorbed by a buffer, and the counterweight, which is constrained by guides to move vertically up and down, is just able to raise the gun to the firing position. A satisfactory rate of fire is claimed for this mounting, which has recently been improved.

Balanced Pillar.—Another type of disappearing mounting for guns of type (b) or (c), known as the balanced pillar, is found on the continent of Europe and in the United States, where it is used for 5" guns and under. A long steel cylinder, which supports the gun and its carriage, has a vertical movement of about 34" in, in an outer cylinder. The inner cylinder and all that it carries is balanced by a counterweight. After the gun is fired it can be brought with its length parallel to the parapet. Then by the action of the mechanism the inner cylinder can be made to sink
The heavy gun cupola is found on the continent of Europe in the armaments of various Powers for guns of type (a), the German...

cylinder backwards with it, draws it off its piston rod L and forces it into the air chamber F. The air in the chambers F and G is at a high initial tension and, on recoil, the air in F is further compressed and forced through the valve H into the chamber G. At the conclusion of recoil the air expands and forces the buffer cylinder to the front, which carries with it with the gun into its loading position; but the valve H closes and the air has to make its way through a narrow hole before it can act on the end of the buffer, thus preventing violent action, which is further guarded against by the control ram M which is bolted into the rear end of the buffer. To prevent leakage of air between the air chamber and the buffer at the gland K the packing employed is a viscous liquid which is in communication by means of the pipe J with the intensifier I. The latter consists of a cylinder containing a piston and rod free to move: the front face of this piston is subject to the pressure of the air in the air chamber, the rear face is in communication with the liquid in the gland. Now, as the piston head is held in position by the pressures on either side of it, and as the effective area of the front face is greater than that of the rear—on account of the rod—the liquid pressure per square inch of the fluid in the gland, &c., must be greater than that of the air in the air chamber, hence the latter cannot escape through the former. The pressure in the chambers F and G is adjusted on preparing for action by an air pump worked by hand. The energy of recoil is further utilized as follows: hydraulic cylinders called compressors are held in the cradle, and in them work rams connected with the cross-head A (see fig. 85): they are also connected with a hydraulic accumulator (not shown) which can be placed in any convenient position in the work, and the power thus stored up is employed for raising the projectiles, for which purpose two lifts are provided. One of these (W) is in the front of the cradle, the other (W') is attached and moves with the latter. Underneath and suspended from the circular gun plat-

Fig. 87.—Longitudinal Section of Part of Cradle of Gun shown in fig. 13, through Axis of Buffer.

The fighting units of coast artillery in the British service are the fire command, the battery command and the group. The limits of a fire command are governed by the possibility of efficient surveillance and control that can be exercised by an individual, and these limits vary much from time to time. Usually a number of forts or emplacements are included in a fire command. The fire command is broken up into battery commands, in every one of which it must be possible for its commander actually to take charge of the guns therein contained in all phases of action. The battery command is divided up into gun groups, each consisting of one or more pieces of like calibre, nature and shooting qualities. As a rule a fire commander is a field officer, a battery commander a major or a captain, a gun group commander a subaltern or senior N.C. officer. In connexion with coast artillery range-finders (q.v.) and electric lights (see COAST DEFENCE) are installed and electric communications established for the chain of command.

V. NAVAL GUNS AND GUNNERY

In dealing with naval guns and gunnery, we shall take the British navy as the basis. At the close of the 19th and at the beginning of the 20th century it appeared that a type of British battleship (see Ship) had been evolved which was stable as regards disposition of armament, and that further advance would consist merely in greater efficiency of individual guns, in improvements of armour rendering possible the protection of greater areas, and in changes of engine and boiler design resulting in higher speeds. The "Majestic," "Glory," "Exmouth," "London" and "Bulwark" classes differed from each other only in such details, all of them subordinate to the main raison d'etre of the battleship, i.e. the number and nature of the guns which she carries.

The strength and disposition of the armament of the ships of these classes were identical except in small details (see fig. 99). In every case the main armament consisted of a pair of 12-in. guns forward and a pair aft, each pair enclosed in a hooded barbette, which was more commonly designated a turret. The turrets were on the midship line, and the guns in each commanded an arc of fire of 240°, i.e. from right ahead to 30° abaft the beam on either side in the case of the fore turret, and from

1 The elevation indicators are now read on a plate provided with a spiral groove, which guides a stud on the reader along the scale of graduations.

2 In a later mark there is no holding-down screw for pivot.
ORDNANCE

A stern to 30° before either beam in the case of the after turret. The secondary armament, consisting of twelve 6-in. guns, was also symmetrically disposed. Two guns on the starboard of either turret (four in the "Majestic" class) were mounted with arcs of fire of from 60° before to 60° abaft the beam, while two guns each side forward and two aft (one forward and one aft in the "Majestic" class) fired through similar arcs to the turret guns, but on their own sides only. Four of these 6-in. guns were mounted on either side of the main deck and two on either side of the upper deck, all being enclosed in casemates.

In the armoured and large protected cruisers built contemporaneously with these classes of battleships, the 9.2-in. gun had been largely mounted, and it was the improvements brought about by practical experience in the rate and accuracy of fire of this gun that suggested its adoption in battleships to replace the whole or a part of the 6-in. armament. During the period in which the battleships referred to above were constructed, the idea of the unarmoured portions of his side diminish his reserve of buoyancy and so impair his sea-going qualities.

These ideas were gradually losing favour; it was realized that the damage done by an armour-piercing shot, whether or not it hit and pierced armour, was limited to its own path, while that done by an armour-piercing shell striking an unarmoured portion of the ship's side was inconsiderable as compared with that effected by a common shell of the same calibre. Further, the area of side, by piercing which an armour-piercing projectile would reach any portion of the propelling machinery or magazines of an enemy, was so small compared with the whole exposed area of his side and upper works that it was scarcely advantageous to fire at it projectiles, the effectiveness of which, if they struck another portion of the enemy, was small in comparison with that of other projectiles which might equally well be fired from the same gun. Again, the lessons of practical experience showed that ships might be and were defeated by shell fire alone, while their armour remained unperforated, and propelling machinery and magazines intact.

All these considerations led to the conclusion that it was to intensity of shell-fire, and especially to the fire of large capacity and high explosive shell, that attention should be directed. At the same time, while the rate of fire of the 6-in. guns, to which great attention had been paid, remained stationary or nearly so, the rate of fire of the 9.2-in. and 12-in. guns had considerably improved, and their ballistic powers rendered possible more accurate firing at long ranges than could be effected with the 6-in. guns. The explosive effect of a shell is said to vary as the square of the weight of its bursting charge. The bursting charge, with shell of the same type, bears a constant proportion to the weight of the shell. Now the weight of the 12-in. shell is 850 lb., that of the 9.2-in. 380 lb., that of the 6-in. 100 lb. Hence it would require fourteen 6-in. shells to produce the same effect as one 9.2-in., and seventy-two to produce the same effect as one 12-in. shell, consequently the 6-in. gun to produce the same shell effect as the 12-in. or 9.2-in. gun must fire 72 times, or 14 times, respectively, faster. The rate of fire of guns in action depends upon a variety of conditions, an important one being that of smoke interference, which tends to reduce the maximum rate of fire of the smaller guns nearer to that practicable with the heavier guns, but the rate of fire of the three guns in question,
under battle conditions, is in the approximate proportions of 1:1.5:4, which would thus produce a shell effect (supposing the hits made by each type of gun to bear a fixed proportion to the rounds fired), in the proportions of 72:22:4, for the 12-in., 9.2-in. and 6-in. guns respectively. This argument of course takes no account of the probably greater effect produced by the dispersion of the larger number of hits of the smaller gun over the exposed area of the target, nor, on the other hand, does it take account of the greater armour-piercing power of the 12-in. shell which would have the result that a larger proportion of the hits from the smaller gun would be defeated by the enemy's armour, and so prove innocuous.

The shell effect forms a strong argument for the weight available for the heavy gun armament of a ship being disposed of in the form only of the heaviest gun available. Another strong argument is that deduced from the fact already stated, that, as the calibre of the gun increases, its ballistic powers enable accurate shooting to be made at a longer range.

The accuracy of a gun at any range depends mainly, for practical naval purposes, on weight known as the "dangerous space," or the limit within which the range must be known in order that a target of a given height may be struck. Again, the dangerous space at any range depends upon the remaining velocity of the projectile at that range, which, as between guns of different calibres but with the same initial muzzle velocity, is greater, the greater the calibre of the gun and weight of projectile, the advantage possessed by the larger gun in this respect being much increased at great ranges. As a practical example, for a target 30 ft. high at a range of 8000 yds., the dangerous spaces of modern 12-in., 9.2-in. and 6-in. guns, which do not differ greatly in muzzle velocity, are 75, 65 and 40 yds. respectively. At whatever range a naval action is to be fought, it is evident that there must be a period during which the enemy is within the practical 12-in. gun range, and outside the practical 6-in. gun range, so that during this period the weight allotted to 6-in. guns will be wasted, and this at the outset of an action, when it is more important than at any time during its progress to inflict damage on the enemy as a means of preventing him from inflicting damage on ourselves. But if all the weight available be allotted to 12-in. guns, the whole of the armament which will bear on the enemy will come into action at the same time, and that the earliest, and consequently most advantageous, time possible. This train of argument led to the substitution of 9.2-in. guns in the 8 "King Edward VII." class (the first of which was completed in 1903) for the upper deck 6-in. guns, and eventually in the "Lord Nelson" and "Agamemnon" (completed in 1908) to the abolition of the 6-in. armament, which was replaced by ten 9.2-in. guns.

At the beginning of the present century the subject of "fire control" began to receive considerable attention, and a short statement is necessary of the causes which render essential an accurate and reliable system of controlling the fire of a ship if hits are to be made at long range. In the first place, even with the 12-in. gun, the range must be known with considerable nicety for a ship to be hit. At a target 30 ft. high, at 8000 yds., for example, the range on the sights must be correct within 75 yds. or the shot will fall over or short of the target. No rangefinder has yet proved itself reliable, under service conditions, to such a degree, and even if one were found, it could not be relied upon to do more than place the first shot in fair proximity to the target. The reason for this lies in the distinction which must be drawn between the distance of a target and its "gun range," or, in other words, the distance to which the shots must be adjusted in order that the target may be hit.

This gun range varies with many conditions, foremost among which are the weight of the gun, the temperature of the ordnance, the force and direction of the wind and other atmospheric conditions. It can only be ascertained with certainty by a process of "trial and error," using the gun itself. The error, or distance which a shot falls short of or beyond the target, can be estimated with a greater approach to accuracy the greater the height of the observer. It is the process of forming this estimate which is termed "spotting," a duty the performance of which calls for the exercise of the most accurate judgment on the part of the "spotter," and which requires much practice in order that efficiency may be secured. In practice, the first shot is fired with the sights adjusted for the distance of the target given by the rangefinder, corrected as far as is practicable for the various conditions affecting the gun range. The first shot is spotted, and the result of the spotting observations governs the adjustment of the sights for the next shot, which is spotted in its turn, and the sights are readjusted until the target is hit. From this time onwards it is (in theory) only necessary to apply the change in range, due to the movements of our own ship and of the enemy, for the interval between successive shots, in order to continue hitting. This change of range, which may be considerable (e.g. 1000 yds. per minute in the extreme case of ships approaching each other directly, and each steaming at the rate of 15 knots), is in practice extremely difficult to estimate correctly, and the spotting is consequently continued in order to rectify errors in estimating the rate of change in range. For various reasons the "gun range," which has been referred to is not the same for different natures of guns. This is mainly on account of the difference in the height attained by their projectiles in the course of their respective trajectories. While it is possible, by careful calibration (i.e. the firing from the several guns of carefully aimed rounds at a fixed target with known range and under favourable conditions for practice), to make the shots from all guns of the same nature fall in very close proximity to each other when the sights of all are similarly adjusted, it has not been found possible in practice to achieve this result with guns of different natures. Consequently guns of each nature must be spotted for independently, and it is obvious that this adds considerably to the elaboration and complication of the fire control system.

This constitutes one of the reasons for the adoption of the uniform armament in the "Dreadnought" and her successors; another important reason lies in the fact that with the present available for the heavy gun armament disposed of in a small number of very large guns, a greater proportion of these guns can be mounted on the midship line, and consequently available for fire on either side of the ship (see fig. 90). Thus in the "Dreadnought," eight of her ten 12-in. guns can bear through a considerable arc on either beam, while in the "Lord Nelson," although all her four 12-in. guns can bear on either beam, half at least of her 9.2-in. armament (i.e. that half on the opposite side to the enemy) will be at any moment out of bearing, and consequently for the time a useless weight. The same principle of a uniform armament of 12-in. guns has been adopted in the "Invincible" type, the only large cruisers designed since the inception of the "Dreadnought." Thus the 12-in. gun forms the sole heavy gun armament of all battleships and large cruisers of the "Dreadnought" era. The gun so carried is known as the Mark X, it is 15 calibres in length, and fires a projectile weighing 850 lb with a charge of cordite of 260 lb, resulting in a muzzle velocity of 2700 ft. per second. The Mark XI gun was designed to be mounted in the later "Dreadnoughts." Following the same line of development as resulted in the Mark X, gun, it is longer, heavier, fires an increased charge of cordite, and has a higher muzzle velocity, viz. of 2960 ft. per second. This gun appears to mark the climax of development along the present lines, since the price to be paid in greater weight, length and diminished durability of rifling is out of all proportion to the small increase in muzzle velocity. Further developments would therefore be looked for in some other direction, such as the adoption either of a new form of propellant or of a gun of larger calibre. A modern gun of 10-in. calibre is found in the battleships "Triumph" and "Swiftsure." The next gun in importance to the 12-in. is the 9.2-in., which forms part of the armament of the "Lord Nelson" and "King Edward VII." classes of battleships, and the principal armament of all armoured cruisers (excepting the "County" class) antecedent to the "Invincibles." The latest gun of this calibre has developed from earlier types in a similar manner to the 12-in., that is to say, it has experienced a gradual increase in length, weight, and weight of charge, with
power, and a douche of water or blast of air, or a combination of both, removes any smouldering fragments of cordite or cartridge material before a fresh round is loaded.

Although there is little difference in principle between the arrangements of the mountings in the later "Majestics" and those in the "Dreadnought," improvements in detail have enabled the interval between successive rounds to be reduced from about 55 seconds in the former case to 25 or 30 seconds in the latter.

In the turrets containing 9-2-in. and 7-5-in. guns, which exist in most British armoured and first-class protected cruisers, the moving weights are, of course, not so large, and, as might be expected, the assistance of hydraulic machinery is not necessary in so many operations. A drawing of a typical 9-2-in. gun and mounting is shown in fig. 92.

Training the turret and elevating the guns are, however, in all cases performed by hydraulic power, as is the raising of the projectiles to their place on the loading tray in rear of the gun, but the breech is opened and closed, and the charge and projectile rammed home, by hand power only, while the gun, after recoil, is forced out again to its firing position by means of springs. A ready supply of thirty-two projectiles is stowed in a "shell carrier," which is a circular trough running on rollers round the turret, but independently of it. When a projectile is required to be loaded into the gun, the shell carrier is rotated until the required projectile is under a hatch in rear of the gun, when the projectile is raised by a hydraulic press on to a swinging loading tray. It is intended that the shell carrier shall be replenished direct from the shell-room during the pauses of an engagement. A new type of 9-2-in. mounting has been installed in the "Lord Nelson" and "Agamemnon," in which greater use is made of hydraulic power with a view to improving rapidity of fire. In this mounting, each projectile is brought up from the shell-room as it is required, and the loading operations are performed by hydraulic power instead of by hand.

The "King Edward VII." class of battleships and "Duke of Edinburgh" class of cruisers are the last ships in which any 6-in. guns have been mounted, and with the exception of the 7-5-in. guns in the "Triumph" and "Swiftsure," these are the largest guns which are worked entirely by hand. Other hand-worked guns are the 4-in. and 12-pounders, which are mounted in small cruisers and destroyers.

The principles of the 6-in., 4-in. and 12-pounder mountings are similar. The rear part of the gun is partially enclosed in a metal cradle, which carries the recoil cylinder and running out spring box. The gun and cradle are balanced for elevation about trunnions on the cradle, which fit into trunnion bearings on the carriage. The latter carries the elevating and training gear, and the whole moving weight is borne by a pivot pin which rotates on a ball bearing. The gun recoils in the line of fire, and the energy of recoil is absorbed by means of the recoil piston, whose rod is secured to the gun, passing over a valve key secured to the cradle, in such a way as to produce a channel of varying sectional area through which the liquid in the recoil cylinder must pass from one side of the piston to the other. Springs run the gun out again after firing into its original position. The breech is opened by the single motion of a hand lever. A "bare" charge is used in the 6-in. and 4-in. guns, with the de Bange type of obturation, while a brass cartridge case has been retained with the 12-pounder, as with the earlier Q.F. guns.

Firing is by electricity, percussion being available as an alternative if required, and the current is usually taken off the dynamo mains of the ship.

Sighting.—The great advances recently made in accuracy of fire have been rendered possible, to a very great extent, by the use of telescopic sighting apparatus. Arrangements are made in all modern sights for the bars or disks which carry the range graduations to be of considerable length or diameter respectively, in order that no difficulty may be found in adjusting the sights for every 25 or 50 yds. of range. In the larger hand-worked mountings, where the laying of the gun for elevation and for direction is effected by two men on opposite sides of the gun, the sights used by them are "cross-connected," i.e. connected by rods and gearing to one another in such a way that, initial parallelism of the axes of the two telescopes having...
a consequently increased muzzle velocity. The latest type, which is known as the Mark XI, and is mounted in the “Lord Nelson” and “Agamemnon,” is 50 calibres in length, weighs 28 tons, and with a charge of cordite of 130 lb gives to a projectile of 380 lb a muzzle velocity of 2875 ft. per second. The 7.5-in. gun forms the secondary armament of the “Triumph” and “Swiftsure,” and is mounted in the armoured cruisers of the “Minotaur,” “Duke of Edinburgh” and “Devonshire” classes. The 6-in., of which there are a very large number aloft in modern, though not the most recent, battleships, and in armoured and first and second class cruisers, is the largest gun which is worked by hand power alone. For this reason, and on account of its rapidity of fire, it was for many years popular as an efficient weapon. It was evolved from the 6-in. 80-pounder B.L. gun, constructed at Elswick, which was the first breech-loader adopted by the Royal Navy, and whose development has culminated in the 6-in. Mark XI. gun of the “King Edward VII.” class and contemporary cruisers, which fires a 100-lb projectile with a muzzle velocity of 2900 ft. per second. It has now only passed out of favour on account of its inferior hitting power at long range as compared with that of guns of larger calibre. The secondary armament of 6-in. guns is still being included in the latest battleship designs of more than one foreign navy—notably that of the Japanese, with their practical experience of modern war at sea—its abandonment in the British Navy can scarcely be considered final. The 4-in. Q.F. gun is mounted in the third-class cruisers of the “P” class as their main armament, and an improved gun of this calibre, with muzzle velocity of about 2800 ft. per second, is mounted in the later “Dreadnoughts,” as their anti-torpedo boat armament.

The increase in size of modern torpedo craft and the increased range of modern torpedoes has led to a reconsideration of the type of gun suitable for the protection of large ships against torpedo attack. The conditions under which the anti-torpedo boat armament comes into play are the most unfavourable possible for accurate gun-fire. The target is a comparatively small one; it comes into view suddenly and unexpectedly; it is moving rapidly, and the interval during which the boat must be stopped, i.e., that between her being first sighted and her arrival at the distance at which she can expect to fire her torpedo within a probability a very short one. Moreover, the great majority of cases the attack will be made at night, when the difficulties of rapid and correct adjustment of sights, and of range-finding and spotting, are intensified. Two requirements then are paramount to be satisfied by the ideal anti-torpedo-boat gun: (1) it must have a low trajectory, so that its shooting will not be seriously affected by a small error in the range on the sights; (2) one shot from it must suffice to stop a hostile destroyer.

For many years it was considered that these requirements would be met by the 12-pounder, which was the anti-torpedo-boat gun for battleships from the “Majestics” to the “Dreadnought,” the 12-pounders mounted in the “King Edwards” and the “Dreadnought” being of a longer and heavier type, giving a higher muzzle velocity. The introduction of a larger gun has, however, been considered desirable, and a 4-in. gun of new type is mounted in the later “Dreadnoughts,” while in the older battleships and large cruisers with secondary armaments it is considered by many officers that the 6-in. guns will prove to be the most effective weapon against torpedo craft. The armament of destroyers being required to answer much the same purpose as the anti-torpedo-boat armament of large ships, namely, to disable hostile torpedo craft, the type of gun used has followed a similar line of development.

Starting with 6-pounders in the first destroyers built, the majority of the new destroyers have a fixed armament consisting of one 12-pounder forward, and four 6-pounders. This armament has been changed in the larger destroyers to one of 12-pounders only, while the latest ocean-going destroyers have two 4-in. guns. Owing, however, to the strength of the decks of such craft being insufficient to withstand the stresses set up by the discharge of a gun giving very high muzzle velocity, the 4-in. gun for use in light craft is one giving 2300 ft. per second muzzle velocity only and has a very long recoil. The 6-pounder and 3-pounder Q.F. guns are no longer to be found as part of the armament of modern ships. A very high rate of fire is obtained in the "semi-automatic" mounting of the 3-pounder, which was last fitted in the "Duke of Edinburgh" class, but for reasons already given guns of this type are no longer required, and the 3-pounder is retained only as a boat gun for sub-calibre practice.

All double-banked pulling boats and all steam-boats are fitted with arrangements for mounting one or two guns, according to the size of the boat; the object of the boat armaments being for use in river operations, for covering a landing, or in guardboats. Three descriptions of gun are used, the 12-pounder 8 cwt. and 3-pounder, light Q.F. guns, and the Maxim rifled-calibre machine gun.

Gun-Mountings.—Gun mountings in the British navy may be divided broadly into two classes, power-worked and hand-worked mountings. The former class includes the mountings of guns of all calibres mounted in turrets or barbettes, also of 9.2-in. guns mounted behind shields; the latter class includes mountings of guns of all sizes up to the 7-in. which are mounted in port-holes or behind shields.

Hydraulic power has been adopted primarily centrally in the British navy for power-worked mountings, although electricity has been experimented with, and has been largely applied in some foreign navies. The principal advantages of hydraulic, as compared with electric, power are its comparative noiselessness and reliability, and the ease with which defects can be diagnosed and rectified. On the other hand, electric power is more easily transmitted, and is already installed in all ships for working electric light and other machinery, whereas hydraulic power, when used, is generally installed for the purpose of working the guns only. The 12-in. guns in the “Majestic” class, following the practice with the earliest heavy B.L. guns, were loaded normally at extreme elevation of 13½°, and the turret had to be trained to the fore and aft line and locked there for each occasion of loading. An alternative loading position was also provided, in which the guns could be loaded at 1° of elevation and with the turret trained in any direction. Loading in the alternative position could, however, only be continued until the limited stock of projectiles which could be stowed in the turret was exhausted. Experience showed that the stock of fire could be obtained by the use of this “all round” loading position, as it was termed, and in the latest ships of the “Majestic” class, and in subsequent battleships, the fixed loading position has been abandoned.

The details of recent 12-in. mountings vary considerably, a drawing of one of the most recent being shown in fig. 91, for which thanks are due to Messrs Vickers, Sons & Maxim, but in the majority of cases there is a “working chamber” revolving with the turret. The introduction of give fixed to the turret has led to increasing the rate of fire by enabling the gun to be disengaged immediately the loading operations are completed. Elevating is by hydraulic power, and is effected by cylinders placed underneath the slide, and the gun is run out again into the firing position by hydraulic power. Loading is carried out by means of a hydraulic rammer, with the tiles in the “run in” position, and at an angle of elevation, which varies with different classes. The most recent mountings loading can be carried out with the gun at any elevation, thus affording considerably greater facility to the gun-layer for keeping his sights on the target during the process of loading, and increasing the rate of fire by enabling the gun to be disengaged immediately the loading operations are completed. Elevating is by hydraulic power, and is effected by cylinders placed underneath the slide, the piston working on an arm projecting forwards. Turning engines are also hydraulic, and much attention has been given to late years to the perfection of elevating and turning gear such as will enable the turret or gun to respond instantly to the wish of the gun-layer, and to move either with considerable rapidity, or very slowly and steadily as would be the case when following a target at long range and with but little movement on the ship. The breech is opened and closed by hand or by hydraulic
The older turret sighting arrangement consisted of two horizontal shafts, one for each gun, running across the turret, which were rotated by pinions geared into racks underneath the gun-slides, the latter remaining of course parallel to the guns. Pinions keyed to these shafts geared in their turn into racks formed on vertical sighting columns in the sighting positions, these columns, which carried the sighting telescopes, accordingly moving up and down with the guns. With this arrangement an appreciable amount of backlash was found to be inevitable, owing to the play between the teeth of the several racks and pinions, and to the torsion of the shafts, and the arrangement was also open to the objection that the telescopes were much exposed to possible injury from an enemy's fire. These defects have been very largely obviated by the "rocking motion sights," which have been fitted in the turrets of the latest British battleships and cruisers. In these sights a sight-bracket is secured to and rotates with the trunnion of the mounting; the sight-carrier and telescope move along the top of the sight-bracket, on a curved arc of which the trunnion is not the centre. When the sight is at zero, the telescope is parallel to the axis of the gun, while to adjust the sight, the sight-carrier with telescope is moved along the curved arc by means of a rack and pinion a distance corresponding to the graduations shown on the range dial, which is concentric with the pinion.

Organization.—The organization of a large ship for action is necessarily highly elaborate. Among the officers, next to the captain, the most important duties are probably those of the fire control officer. He is in communication by telephone or voice tube with each of the several units composing the ship's armament. This office is usually filled by the gunnery lieutenant. In the conning tower with the captain is the navigating officer, who attends to the course and speed of the ship, assisted by petty officers to work the wheel and engine-room telegraphs. The torpedo lieutenant, or another officer at the torpedo director, is also in the conning tower, prepared to fire the torpedoes if opportunity offers. Other officers of the military branch, and marine officers, are in charge of various sections of the "quarters."

The rate of advance in naval gunnery has been much accelerated since 1902. The construction of the "Dreadnought," which embodied a new principle both in nature and disposition of armament, the rise of the United States and Japanese navies to the first rank, and the practical experience of the Russo-Japanese war, were all factors which contributed to the increase of the normal rate of advance due to progress in metallurgy and engineering science. In the British as well as in other navies, notably those of Germany, the United States and Japan, ever-increased attention is being devoted to the attainment of a rapid and accurate shell-fire, and large sums are being expended upon fire control instruments and elaborate aiming and sighting appliances. Size of armaments, power of guns, resistance of armour, efficiency of projectile, and, above all, rapidity and accuracy of fire, all seem to be advancing with giant strides. But there are two important ingredients of naval gunnery which are not subject to change: the human factor, and the factor of the elements—wind, sea and weather. The latter ensures at any rate one datum point to the student of the science, that is, that the extreme range in action is limited by the maximum distance at which the enemy can be clearly seen, which may be considered to be a distance of 8000 to 10,000 yds. The permanence of the human factor assures that, however great the advance in material, and, provided that no great discrepancies exist in this respect between opposing navies, success at sea will be the lot of the nation whose officers are the coolest and most intelligent, whose men are the best disciplined and best trained, and whose navy is in all respects the most imbued with the habits and traditions of the sea.
ORDOVICIAN SYSTEM

ORDOVICIAN SYSTEM, in geology, the group of strata which occur normally between the Cambrian and the Silurian above; it is here regarded as including in ascending order the Arenig, Llandeilo, and Caradoc or Bala series (qq.v.). The name was introduced by C. Lapworth in 1879 to embrace those rocks—well developed in the region formerly inhabited by the Ordovices—which had been classed by Sir R. Murchison as Lower Silurian and by A. Sedgwick in his Cambrian system. The term is convenient and well established, but Lower Silurian is still used by some authors. The line of demarcation between the Ordovician and the Cambrian is not sharply defined, and beds on the Tremadoc horizon of the Cambrian are placed by many writers at the base of the Ordovician, with good palaeontological reasons.

The rocks of this system include all types of sedimentation; when they lie flat and undisturbed, as in the Baltic region and Russia, the sands and clays are as soft and incoherent as the similar rocks of Tertiary age in the south of England; where they have been subjected to powerful movements, as in Great Britain, they are represented by slates, greywackes, quartzites, chert-, arkose- and graptolite-schists, amphibolites and other products of metamorphism. In Europe the type of rock varies rapidly from point to point, limestones, shales, sandstones, and conglomerates being found within limited areas; but in northern Europe particularly the paucity of limestones is a noteworthy feature in contrast with the rocks of like age in the south, and still more with the Ordovician of North America, in which limestones are prevalent. In the Highlands of Scotland, in north-west England, in Wales and Ireland, there are enormous developments of contemporaneous lavas and tuffs and their metamorphosed representatives; tuffs occur also in Brittany, and lavas on a large scale in Nova Scotia and New Brunswick.

Distribution.—The Ordovician system is widely distributed. The accompanying map indicates roughly the relative positions of the principal land-masses and seas, but it must be accepted with reserve. A study of the fossils appears to point to the existence of definite faunal regions or marine basins. The Ordovician rocks of the British Isles seem to have been deposited in a north Atlantic sea which embraced also the north of France and Belgium. Confluent with this sea on the east was a rather peculiar basin which included Bohemia, southern France, Spain, Portugal, the eastern Alps, Thrace, Friesland, and the Kellanner. Another European basin, probably separated from the Bohemian or Mediterranean sea in early Ordovician times, lay over the Baltic region, Scandinavia, the Baltic provinces and north Germany, and communicated eastwards by way of Russian Poland and central Russia with far eastern Atlantic sea. The lagoonal character of some of the rocks of the Tunguska region of Siberia may perhaps be indicative of continental border conditions in that quarter.

Some of the principal subdivisions of the Ordovician rocks are enumerated in the table. Owing to the universal distribution of the graptolites, the correlation of widely separated areas has been rendered possible wherever the muds and shales, in which their remains are preserved, are found. Where they are absent the correlation of the minor local subdivisions of distant deposits is more difficult. In Great Britain, through

Tremadoc beds, Ceratopyge beds, and beds with Euloma-Niobe fauna here regarded as Cambrian: not invariably present.

C. Lapworth and his school, and J. E. Marr and the Cambridge school, and in Scandinavia and the Baltic region, through W. C. Brögger, S. A. Tulberg, F. Schmidt and others, the most elaborate subdivision of the Ordovician rocks has been attained.

In the Baltic provinces of Russia, F. Schmidt describes the following stages, in descending order: (Stage E) the Lyckholm and Borkholm zones, a highly fossiliferous series, equivalent to the Middle Bala of Britain; many of the limestones are largely formed of Radiolaria and other calcareous algae. (D) The Wesenberg zone = Bala. (C) Jewe beds, Kuckers Shale (bituminous limestones and marls = Brandschiefer). Echinophyllum
ORDOVICIAN SYSTEM

Ordovician System. In the Ordeovician, the transition from the Cambrian to the Devonian, certain features of the earth's crust were developed. In the Ordovician, the earth's crust was unstable, with numerous volcanic and sedimentary events. This period is characterized by the development of the Ordovician System, which includes several important faunas and floras.

The Ordovician System is divided into several periods, each with its own distinct characteristics. The most important of these are the Cambrian, Silurian, and Devonian periods. The Ordovician System is characterized by the development of the world's first true oceans, with the formation of the Tethys Sea and the separation of the supercontinent Pangea. This period also saw the development of the world's first true land plants, which began to colonize the land.

The Ordovician System is known for its abundant and diverse fossil record, with a wide variety of marine and terrestrial organisms. The most important of these are the Ordovician trilobites, which are one of the most common and well-preserved fossil groups of the period.

The Ordovician System is also known for its many important volcanic events. The most important of these are the Archean and Proterozoic volcanic events, which were responsible for the formation of the world's first true oceans. These volcanic events also played a key role in the development of the world's first true land plants, which began to colonize the land.

The Ordovician System is also known for its many important tectonic events. The most important of these are the development of the Tethys Sea and the separation of the supercontinent Pangea. These tectonic events played a key role in the development of the world's first true oceans, with the formation of the Tethys Sea and the separation of the supercontinent Pangea.

Overall, the Ordovician System is a period of great importance in the history of the earth, with a wide variety of important events and developments. The Ordovician System is one of the most important periods in the history of the earth, and its study is important for understanding the history of the earth and its development.
includes north-west and south-west France, Spain, Italy, the Alps, the Fichtelgebirge, east Trurungia, Harz and Rhenish Mountains.

ORDU (anc. Cotyora, where the "Ten Thousand" embarked for home), a town on the N. coast of Asia Minor, between Samsun and Karsand, connected with Zara, and so with Sivas, by a carriage road, and with Constantinople and Trebizond by steamer. Pop. about 6000, more than half Christian. Ordu has exceptionally good Greek schools, and a growing trade in filberts. 

ORDUIN—ORE-DRESSING

ORDUIN—NASHCHOIN, ATHANASY LAURENTEVICH (7–1680), Russian statesman, was the son of a poor official at Pskov, who saw to it that his son was taught Latin, German and mathematics. Athanasy began his public career in 1642 as one of the delineators of the new Russo-Swedish frontier after the peace of Stolboda. Even then he had a great reputation at Moscow as one who thoroughly understood German and things. He was one of the first Muscovites who diligently collected foreign books and manuscripts, as the nine Latin works being sent to him at one time from abroad. He attracted the attention of the young tsar Alexius by his resourcefulness during the Pskov rebellion of 1650, which he succeeded in localizing by personal influence. At the beginning of the Swedish War, Ordun was appointed to a high command, in which he displayed striking ability. In 1657 he was appointed minister-plenipotentiary to treat with the Swedes on the Narova river. He was the only Russian statesman of the day with sufficient foresight to grasp the fact that the Baltic seacoast, or even a part of it, was worth more to Muscovy than ten times the same amount of territory in Lithuania, and, despite ignorant jealousy of his colleagues, succeeded (Dec. 1658) in concluding a three-years' truce whereby the Muscovites were left in possession of all their conquests in Livonia. In 1660 he was sent as plenipotentiary to a second congress, to convert the truce of 1658 into a permanent peace. He advised that the truce with Sweden should be prolonged and Charles II. of England invited to mediate a northern peace. Finally he laid stress upon the immense importance of Livonia for the development of对外贸易. On being overruled in the negotiations, he was last employed the negotiations for confirming the truce of Andrussovo (September 1660; March 1670). In January 1671 he heard of him as in attendance upon the tsar on the occasion of his second marriage; but in February the same year he was dismissed, and withdrew to the Krupetsky monastery near Kiev, where he took the tonsure under the name of Antony, and occupied himself with good works till his death in 1680. In many, he anticipated Peter the Great. He was absolutely incorruptible, thus standing, morally as well as intellectually, far above the level of his age.

See S. M. Solovoev, History of Russia (Rus.), vol. xi. (St. Petersburg, 1895, seq.); V. Ikonnikov, "Biography of Ordun-Nashchokin" (in Rascheye Starino, Nos. 11–12 (St. Petersburg, 1883); R. Nisbet Bain, Thames and Severn (London, 1886); R. G. R. B.)

ÖREBO, a town of Sweden, capital of the district (län) of Örebro, lying on both banks of the Svartr and a mile above its entrance into Lake Hjelmar, 135 m. W. of Stockholm by rail. Pop. (1900), 22,013. In great part rebuilt since a fire in 1854, it has a modern appearance. An ancient castle, however, with four round towers, remains on an island in the stream. It is used as a museum. There may be mentioned also the church of St Nicholas, of the 13th century; and the King's House (Kungsstuga), an old and picturesque timber building. In front of the modern town hall stands a statue, by Karl Gustav Qvarnström (1810–1867), of the patriot Engelbrecht (d. 1436), who was born here. The Swedish reformers of the 16th century, Olaus and Laurentius Petri, are commemorated by an obelisk. Örebro is in close connexion with the iron-mining district of central Sweden; it has mechanical works and a technical college. A large trade is carried on, by way of the Örebro canal and lakes Hjelmar and Målár, with Stockholm.

Örebro was in existence in the 11th century. Its castle, erected by Birger Jarl in the 13th century, played an important part in the history of Sweden; and no fewer than twenty diocesan or important assemblies were held either in the castle or in the town. Such were the Örebro concilium of 1537, the diet of 1540 in which the crown was declared hereditary, and that of 1810 when Bernadotte was elected crown prince. 

ORE-DRESSING, one of the principal processes in the work of mining (q.v.). When the miner hoists his ore to the surface, the contained metal may be either in the native uncombined state, as, for example, native gold, native silver, native copper, or combined with other substances forming minerals of more or less complex composition, as, for example, telluride of gold, sulphide of silver, sulphide of copper. In both cases the valuable mineral is always associated with minerals of no value. The province of the ore-dresser is to separate the "values" from the waste—for example, quartz, felspar, calcite—by mechanical means, obtaining thereby "concentrates" and "tailings." The province of the metallurgist is to extract the pure metal from the concentrates by chemical means, with or without the aid of heat. There are also a number of non-metallic minerals which do not have any value, and are either waste or subject to some form of mechanical preparation; among them are diamonds, graphite, corundum, garnet, asbestos and coal. Ore-dressing, for the purposes of this article, may be divided into three parts: (1) properties of minerals which render aid in their separation; (2) simple operations; (3) operations combined to form processes or mills.

1. The specific gravity of minerals varies greatly, some being heavy, others light. The rate of settling in water is affected by the specific gravity in this way: of two particles of the same size but different specific gravity, the heavier settles more rapidly than the lighter, while two particles of different specific gravity which settle at the same rate in water, that of higher specific gravity is of smaller diameter than the other. The same statement is true of separation by gravity, the heavier particles settling in air, and in regard to momentum in air when the particles are thrown out in a horizontal direction. Colour, lustre and fracture are of especial value in hand-picking, to aid the eye in selecting the mineral sought. Instances are, of colours, the blue to purple lustre, the red to violet, and the yellow lustre of limonite, the brass yellow of chalcopyrite, the pale metallic yellow of pyrite; of lustres, the vitreous of quartz, the adamantine of diamond and cerussite, the resinous of blende, the earthy of limonite, and the pearly of sphalerite. The shapes of particles of felspar and galena, the conchoidal fracture of quartz and pyrite, the granular of some forms of magnetite and blende. Magnetism is a most direct and simple method of separating minerals where it is available. The discovery that by the use of electro-magnets of great
power minerals formerly regarded as non-magnetic are attracted, has made it possible to separate several classes of minerals present in an ore; for example, the strongly magnetic mineral may first be taken out, then the mildly magnetic, and last the weakly magnetic, the non-magnetic being left behind. As the action of the highly burned particles of gold issuing with the sand from the stamp mill come in contact with an amalgamated copper plate, for they are instantly plated with mercury and adhere to the copper, while the sand is carried forward by the water; by perfect separation of the gold from the sand is effected. In the South African diamond fields it has been found that if the diamond-bearing sand is taken in a stream of water over a smooth surface covered with a suitable coating of grease, the diamonds will adhere to the grease while the sand does not.

2. The concentration of ores always proceeds by steps or stages. Thus the ore must be crushed before the minerals can be separated and certain preliminary ore dressing or simple operations must precede the final operations which produce the finished concentrates. The more important of these simple operations will now be described. The ore as mined contains the valuable minerals attached to and enclosed in lumps of waste rock. The province of crushing or disintegrating is to sever or unlock the values from the waste, so that the methods of separation may then be applied to the ore. In crushing ores it is found wise to progress by stages, coarse crushing being done by one machine, medium by another, and fine by a third. Coarse crushing is performed by stamps or chisels. The size of the Blake type (fig. 1) or the Gates Comet type (fig. 2). All of these machines break by direct pressure caused by a movable jaw, as (figs. 1, 2), approaching towards and receding from a fixed jaw, b. The largest ever fed to a breaker is 32 in. diameter, and the smallest size to which a breaker can reduce a lump of ore is about \(\frac{1}{2}\) in. diameter. The machine is generally supplied with ore in lumps not larger than 9 in. in diameter, and crushes them to about 3 in. in diameter. Medium-size crushing is performed by rolls (fig. 3) crush by direct pressure caused by the ore being drawn between two revolving rolls held closely together. They make the least fine or fines to be lost in the subsequent treatment, and are therefore preferred for all brittle minerals. The steam stamp works upon the same principle as a steam hammer, the pestle being formed by steam pressure acting through piston and cylinder with great crushing force in the mortar. Steam stamps have been very successful with the native copper rock, because the mortar is a fine meal of leaves, flakes and filaments of copper, and render them susceptible of concentration, which rolls do not. Fine crushing is done by grinding stamps, of which the most common are centrifugal roller mills, by amalgamating pans, by ball mills, by Chile edge-stone mills, by tube mills and by arrastras. The gravity separators and machines for about the third size. Crushing is the frequent revolution of the cam gives a more or less rapid succession of blows. Gravity stamps are especially adapted to the fine crushing of gold ores, which they reduce to \(\frac{1}{16}\)-in. and sometimes even to \(\frac{1}{24}\)-in. grains. The blow of the stamp upon the fragments of quartz not only liberates the fine particles of gold, but brightens them so that they are quickly caught upon the amalgamating plates (fig. 4) is a pestle of good steel. The amalgamating plates are suited to fine crushing of middle products, namely by-products composed of gold containing both values and waste, since they have their edges rounded by the action of a roller, rolling on the inside of a steel ring, both having vertical axes. The amalgamating pan is suitable for grinding silver ores for amalgamation where the finest grinding is sought, together with the chemical action from the contact with iron. It crushes by a true grinding action of one surface sliding upon another. The Chile edge-stone mill is employed for the finest grinding ever used preparatory to concentration. The arrastre or drag-stone mill grinds still finer for amalgamating. The ball mill is a horizontal revolving cylinder with iron balls in it which do the grinding; the pulverized ore passes through screens in the cylinder wall. It is a fine grinder, making a small amount of impalpable slimes. It is used for preparation for concentrating. The tube mill is of similar construction, but it is fed through the hollow shaft at one end and discharged through the hollow shaft at the other; the finely ground ore is floated out by water; it is used for a large proportion of impalpable slimes. It is used for preparation for cyaniding of gold. A considerable class of workable minerals, among which are gold, iron and surface phosphates, contain worthless clay mixed with the valuable material, the removal of which is accomplished by a washing. It is concluded by a classifier consisting of a long narrow cylinder revolving in a trough which is nearly horizontal. Upon the cylinder are knives or pins or grease to an angle, which serve the double purpose of bruising and disintegrating the clay and of conveying the cleaned lump ore to be discharged at the upper end of the trough, the water meanwhile washing away the clay at the lower end.

Roasting for Fribility.—When two minerals—metallic, for example, pyrite and cassiterite (tin ore)—one of which is decomposed and runs free of gold and the other—pyrite—oxidizes and forms pyritic oxide, are roasted in a furnace, the pyrite becomes porous oxide of iron, while the cassiterite is not changed. A gentle crushing and washing operation is performed on this material, and float away the lighter iron oxide, leaving the cleaned cassiterite behind. Sizing.—This is the first of the preliminary operations which is found useful in concentration, for dividing an ore into a number of portions graded from coarse sizes down to finer sizes. Each size is fed upon a machine, namely, on its respective machine. If crushed ore is sifted upon a screen with holes of definite size, two products will result—the oversize, which is unable to pass through the screen, and the undersize, which does pass. If the latter size be sifted upon a second screen, a smaller hole will again make another oversize and undersize. The operation can be repeated with more sieves until the desired number of portions is obtained. P. von Rittinger adopted for close sizing the following diameters in millimeters for the holes in a set of screens: 64, 45, 2, 32, 22-6, 16, 11, 8, 5, 6, 4, 2-8, 2, 1, 1-4. Each of these holes has an area double that of the one next below it; this may be called the screen ratio. A process which does not separate close sizing might use every other screen of the above set, and in extreme cases even every fourth screen. In mills the screen ratio for coarse sizes often differs from that for fine. Sizing is done by cylindrical screens revolving upon their inclined axes (fig. 5), by flat shaking screens, and by fixed screens with a comparatively steady stamp. Either wire cloth with square holes or steel plate punched with round and deintegrating the clay and of conveying the cleaned lump ore to be discharged at the upper end of the trough, the water meanwhile washing away the clay at the lower end. Roasting for Fribility.—When two minerals—metallic, for example, pyrite and cassiterite (tin ore)—one of which is decomposed and runs free of gold and the other—pyrite—oxidizes and forms pyritic oxide, are roasted in a furnace, the pyrite becomes porous oxide of iron, while the cassiterite is not changed. A gentle crushing and washing operation is performed on this material, and float away the lighter iron oxide, leaving the cleaned cassiterite behind. Sizing.—This is the first of the preliminary operations which is found useful in concentration, for dividing an ore into a number of portions graded from coarse sizes down to finer sizes. Each size is fed upon a machine, namely, on its respective machine. If crushed ore is sifted upon a screen with holes of definite size, two products will result—the oversize, which is unable to pass through the screen, and the undersize, which does pass. If the latter size be sifted upon a second screen, a smaller hole will again make another oversize and undersize. The operation can be repeated with more sieves until the desired number of portions is obtained. P. von Rittinger adopted for close sizing the following diameters in millimeters for the holes in a set of screens: 64, 45, 2, 32, 22-6, 16, 11, 8, 5, 6, 4, 2-8, 2, 1, 1-4. Each of these holes has an area double that of the one next below it; this may be called the screen ratio. A process which does not separate close sizing might use every other screen of the above set, and in extreme cases even every fourth screen. In mills the screen ratio for coarse sizes often differs from that for fine. Sizing is done by cylindrical screens revolving upon their inclined axes (fig. 5), by flat shaking screens, and by fixed screens with a comparatively steady stamp. Either wire cloth with square holes or steel plate punched with round and deintegrating the clay and of conveying the cleaned lump ore to be discharged at the upper end of the trough, the water meanwhile washing away the clay at the lower end.
ORE-DRESSING

Box classifiers are suited to treating finer sizes than the hydraulic classifiers, and therefore follow them in the mill treatment.

**Picking Floors.** The first of the final operations of separation, are areas on which men, boys or girls pick out the valuable mineral which is rich enough to ship at once to the smelter. The picking is often accompanied by crushing. Picking is carried out with a hammer and a box classifier. Picking out the values by hand has the double advantage that it saves the power and time of crushing, and prevents the formation of a good deal of fine slimes which are difficult to save.

Jigs treat ores ranging from $1\frac{1}{2}$ in. of water down to $\frac{1}{16}$ in. If an ore is intermittently pulsed by current of water is passed up through a horizontal sieve on which is a bed of ore, the heavy mineral and the quartz quickly form layers, the former beneath the latter. The machine by which this work is done is called a jig, and the quartz overflows at the other. Central water ("hydraulic water") is brought by the pipe, $i$, into the space, $g$, below called the hutch, to regulate the condition of the bed of ore on $a$. The constantly accumulating bed of concentrates is either discharged through the sieve into the hutch, $g$, or by some special device at the side. On jigs where the concentrates pass through the sieve, a bed of heavy mineral grains too large to pass holds back the lighter quartz. The quartz overflow from one sieve, $a$, generally contains much value to be thrown away, and it is therefore jigged again upon a second sieve, $b$. In jelging difficult ores, three, four, five and even six sieves are used. A succession of sieves gives a set of products graded both in kind and in richness, the heavier minerals are caught first, the lighter, as pyrites and blende, coming later. The best jigging is done upon closely sized products using a large amount of clear water added beneath the sieve. Very good jelging may, however, be done upon the products of hydraulic classifiers, where the heavy mineral in small grains and the quartz large is by using a bed on the sieve and diminished hydraulic water, which increases the suction or downward pull by the returning plunger.

**Bumping Tables.** Bühler's table is a rectangular gently sloping plane surface, which by a bumping motion throws the heavy particles to one side while the current of vanning motion is substituted for the harsh bump; they have a greatly increased width and a set of riffle blocks, $b$, at the direction of flow, $c$, running in the parallel towards the side where the concentrates are discharged, $d$. This combination has produced a table of great efficiency and capacity for treating grains as small as $\frac{1}{16}$ in. in diameter down to $\frac{1}{256}$ in. or even finer. The capacity on $\frac{1}{16}$ in. pulp is from 15 to 25 tons in twenty-four hours. In the Wilfley table (fig. 8) and those derived from it a gentler vanning motion is substituted for the harsh bump; they have a greatly increased width and a set of riffle blocks, $b$, at the direction of flow, $c$, running in the parallel towards the side where the concentrates are discharged, $d$. This combination has produced a table of great efficiency and capacity for treating grains as small as $\frac{1}{16}$ in. in diameter down to $\frac{1}{256}$ in. or even finer. The capacity on $\frac{1}{16}$ in. pulp is from 15 to 25 tons in twenty-four hours.

**Vanners.** Machines are used for the handling of endless belts, generally of rubber with flanges on the two sides. The belt (fig. 9) travels up a gentle slope, $a$, on horizontal transverse rollers, and is shaken about 200 times a minute. The direction of flow, $c$, running in the parallel towards the side where the concentrates are discharged, $d$. This combination has produced a table of great efficiency and capacity for treating grains as small as $\frac{1}{16}$ in. in diameter down to $\frac{1}{256}$ in. or even finer. The capacity on $\frac{1}{16}$ in. pulp is from 15 to 25 tons in twenty-four hours.

**Riffles.**-When wooden blocks or cobble-stones of uniform size are placed in the bottom of a sluice, the spaces between them are called riffles; and when gold-laden gravel is washed by riffles, the deep cavities between them are called by the same name. The concentrate is washed down the riffles, and any gravel or eddies are produced, in which the gold and other heavy minerals settle.

**Kieves.**-The kieve or dolly-tub is a tub as large or larger than an ordinary oil-barrel, with screens fastening in the way of a funnels, and containing a central little vertical shaft, with hand crank at the top and stirring blades like those of a propeller at the bottom. Fine concentrates from riffles or dolly-tubs are still further enriched by treatment in the kieve. The kieve is filled perhaps half full of water, and the paddles set in motion; concentrates are now shovelled in until it is nearly full, the rotation is continued a little longer and then the shaft is quickly withdrawn and
the side of the kieve steadily thumped by a bumping-bar as long as settling continues. When this is completed, the water is siphoned off, and the end sand skimmed off and sent back to the kieve, and the enriched bottom swelled out and sent to the smelter.

3. In designing concentration works, the millwright seeks to combine the various methods of coarse and fine crushing and of preliminary and final concentration that he will obtain the maximum return from the ore with the minimum cost. Some of the more important of these mill schemes will now be described.

The hand-jig process used for the zinc and lead ores of Missouri is first to clean the ore from adhering clay by raking it back and forth in a sluice with a running stream of water, and then show it up in a kieve, which has the advantage of being rapid and easy to change, and of being hand-rolled and under-size. The process is hand-picked into lead ore, and the latter is jigged upon a hand-jig and yield several layers of minerals removed by a hand-skimmer. The top skimmings are waste, the under-skimmed middlings are next to be jiggered over, and the bottom skimmings go to a second jig with finer screen. The coarsest of the hand product, i.e., the product which passed through the sieve and settled at the bottom of the tank, goes to the second jig, the finest is sold to be re-crushed, and the second skimmings are sent back to the first jig, middle middlings which are zinc concentrates, and bottom skimmings which are lead concentrates.

In Missouri, zinc-concentrating mill the ore containing blende and calamine with a little galena is in very large crystallizations and contains, when crushed, very little in the way of included grains. It is crushed by Blake breaker and rolls, to pass through a sieve of 10 mm. and to reject that is not crushed, carried through six consecutive sieves, yielding discharge and product from each sieve, and tailings to waste. The earlier discharges are finished products, while the later are re-crushed and re-treated on the same jigs. The zinc concentrates are treated with five standard tables, and yield galena from the first discharge and zinc ore from the others. The quantity of such jigs is very large, even to 80 or 100 tons per day of ten hours.

In the diamond washing of British Kongo and its northern districts, the material taken from the mines is washed by exposure to the air and rain for several months, and the softening and disintegration thus well started are completely finished by stirring in vats with water. Breaker and rolls are used to hasten the process, but the larger diamonds were used to pass through the screens and were rejected. The material from the various screens was jigged and picked, and of the jig concentrates containing about 2% of diamonds the coarse are hand-picked and the finer are treated on a greased surface. Let us take the jigs to their values in brittle minerals, and are concentrated in mills which vary somewhat according to local conditions; the one here outlined is typical of the class. The ore is crushed by breaker and rolls, and separated into a series of products diminishing in size at each stage of the process. The product of the last stage is treated with jigs, which are classed with the classifier. All the products of screens and hydraulic classifiers are jigged on separate jigs yielding concentrates, middlings, and tailings; those of the box classifier are treated on the slime-table, vanner or Wilfley table, and the results are mixed with those from the jigs.

The coarser middlings contain material attached to the furs of quartz and are therefore sent back to be re-crushed and re-treated. The finer middlings contain valuable material difficult to save from their shape only, and are sent back to the same machine or to another to be finished.

The native copper rock from Lake Superior is broken by powerful breakers, occasionally preceded by a heavy drop-hammer weighing a ton or more. The operation is accompanied by hand-picking, yielding a product of copper rock which passes through a water aspirator at the smelter; at some mines a grade second is also picked out which goes to a steam finishing-hammer and yields clean mass copper for the smelter and rich stamp stuff. The run of rock which passes by the hand and hand-picking equipment with screens 3 in. apart, and goes to the steam stamps. The stamp rocks the круч и discharges coarse copper through a pipe in diameter, in which it descends against a rising stream of water which lifts out the big particles. Copper is thus sold from the top of the kieve, and a gate at the bottom. The rest of the rock is crushed to pass through a screen with round holes in diameter, in diameter, more or less. This is treated in hydraulic classifiers with four pockets, the products from the pockets being jigged by hand or by screens to separate the minerals. The screens included grades for the grinder, partially concentrated products for the finishing-jigs, and tailings which go to waste. The overflow of the hydraulic classifier runs to a tank of which the overflow is sent to waste in order to diminish the quantity of concentrate, and the underflow is treated upon the slime-bales, yield concentrates, middlings, and tailings. The middlings are re-treated. All the finished concentrates put together will assay from 60 to 80% of copper according to circumstances. The extraction from the rock from 50 to 80% of the copper contained in it.

Cornwall Tin.—Tinstone in Cornwall occurs associated with sulphides, wolfram, quartz, felspar, slate, &c., and is broken by spalling-hammers to 3-in. lumps. Hammers make less slimes than the rock-breakers, and they also break the ore more advantageously for the hand-picking. The latter rejects waste, removes as far as possible the hurtable wolfram, and classes the values into groups according to richness. Gravity or pneumatic stamps then crush the ore to 1/4 in., and strips (a species of long rectangular baffle) yield heaviest concentrates from which the coarse and finest middlings are sent separately to circular baffles, and the last to frames. The baffle yield concentrates, middlings, and tailings: the middlings are treated, the tailings are all waste; the concentrates are still further enriched, and the tailings are further treated. The concentrates are shipped to the smelter. The long slimes are treated on frames, the concentrates of which go to baddles; of these the concentrates go to kieves.

The Missouri zinc-lead sludge mill takes the finest part of the hand product of the hand-jigs. The treatment begins on revolving screens with two sizes of holes, 25 mm. and 1 mm.: these take out two coarser sizes, of which the coarsest is waste and the other is jigged directly, yielding a second skimmings return. The finest size, which is the largest product. It is fed to a convex circular baffle (first baffle), and yields a coarser product at the outer part of the circle and a finer product in the inner. The finer product is treated by a series of baddles which very slowly rotate, but in general are as follows: fed to a second baffle it yields zinc and lead ore in the centre, the next zinc, next middlings which come back and, outside of all tailings, the zinc-lead ore is on one side until enough has accumulated to make a baffle run, when it is run up to the third baffle, and the concentrates go to the second baffle, which is treated in much the same way as the first, and yields a zinc-lead product, which simplifies the series of baddles necessary.

Gold Mill.—Gold ores usually contain their value in two conditions—the free gold, which can be taken out by mercury, and the amalgam, which is usually treated with carbonaceous material combined with compounds of sulphur, tellurium, &c. The usual gold-milling scheme is to crush the ore by rock-breaker to about 1 in. diameter, and then to crush with water and mercury, a little at a time, so the amalgamation is completed at the first moment and the gold is liberated. The pulp leaves the mortar through a screen with holes or slots to in width, and is then passed over amalgamated plates of copper or silver-plated copper. The free gold, amalgamated by the mercury, adheres to the metallic surface, and is washed out of the pulp by the mercury which flows on through mercury traps to catch any of the mercury. The plates and mortar are periodically cleaned up, the plates being scraped to recover the amalgam and leaching of the ground condition to do their work; if plated, they are in the mortar, they are cleaned in the same way. The residue of partly crushed ore in the mortar, with amalgam and free mercury scattered through it, is ground for a time in a ball mill, passed to a second mortar, and this is treated in the same way, the mercury flows away from the mercury traps flows to a Frue vanner or Wilfley table, on which it yields concentrates for the chlorination or smelting and tailings: these are waste when the heavy mineral is of low value. The amalgamated gold, after these second stages, they still contain values of very fine sizes which can and should be saved. Recent improvements in California for saving this material have been made. The vanner tailings are sent to a fine classifier, from which the light overflow only is saved; this is treated upon canvas tables yielding concentrates and tailings, and these are treated upon a little end-shake vanner with steep slope and rapid travel, give clean, very fine, high-grade concentrates for the chlorination works.

Native Ores.—The brown ores of iron from surface deposits are contaminated with a considerable amount of clay and some quartz. The crude ore from surface pits or shallow underground workings is treated in a log-washer and yields the fine clay, which runs to washers and is then treated by hand-picking, to free it from the little quartz, or jigged if it contains too much quartz. The magnetic oxide of iron occurs associated with felspar and quartz, and can often be separated from them by the magnetic process. The pieces are rolled into a size varying from 1/4 to 1/8 of an inch in diameter, goes to a magnetic machine which yields (1) the strongly magnetic, (2) the weakly magnetic, and (3) the non-magnetic portions. The second or medium portion is again treated with the magnetic machine, and is therefore re-crushed and sent back to the magnets; the strongly magnetic portion is shipped to the furnace; and the waste to the dump heap. In concentrating by water certain zinc sulphides, silicious material (carbonate of iron) and is therefore sent to the furnace. By a carefully adjusted roasting of the product in a furnace the siderealite is converted into magnetic oxide of iron, and can then be separated by magnet from the zinc ore. A special magnet of very high power, known from its inventor as the Wetherill magnet, has been designed for treating the Franklinite of New Jersey, a mineral which is non-magnetic in the usual machines. The ore, crushed by breakers and rolls and hand-picked to remove garnet, is treated upon a belt with a roughing magnet to take out the most magnetic portion, and then very closely sized by screens with
Asbestos, when of good quality, is in compact masses, which by suitable bruising and beating are resolved into fine fibres. The Canadian asbestos is associated with serpentine, and is crushed and washed out in the usual manner. The cotter is "broken" or "sieved," and the smaller fibres are removed by hand-picking and are crushed with rolls carefully set so as not to break the fibre; this product is then sized by screens and the various sizes are sent to the Cyclone pulverizer, which by being adjusted to different sizes of particles can be fitted to the treatment of asbestos, settling-chamber in some cases and wooden frames in others. When it is desired to precipitate out the larger fibres an additional treatment is given them, and they are then washed and bleached with a solution of potassium permanganate and a little acetic acid, and subjected to a final washing before being dried and sent to market.

The usual method of dressing corundum and emery, after the preliminary breaking, is to treat the material in an edge-stone mill fitted with light wooden rollers. The action is that of grinding one particle against another. The size of the particles is regulated by the space between the rolls or by the rollers themselves. When the dry material is ground, the powdered mixture is usually carried off with water or air. When the material is wet-ground, the water or air is passed through the grinding mill. The usual size of the particles is determined by the application for which the material is intended. Corundum is used for the manufacture of abrasive grinding wheels, emery for the manufacture of polishing wheels.

Oregon, by thrown moved other land and the minerals settles the treatment fitted treated Asbestos, settling-chamber the Canadian fibrous holes is zinc usual range and the cleaning. Aultz, again conveyed in its usual linear range of the mountains. Of the minerals treated by various methods in the mining of any given material, the one most commonly used is the electric furnace. This furnace is capable of producing a large amount of heat, and can be used for the melting of any material that is required to be melted. The furnace is usually constructed of iron or steel, and is provided with a rotating hearth to which the material is added. The heat generated in the furnace is sufficient to melt the material, and the molten metal is then poured into a mold. The mold is usually made of clay, and is designed to produce a cast of the desired shape. The process of casting is repeated until the desired amount of metal has been produced.
The most important stream is the Columbia river, which forms the northern boundary for 300 m. and receives directly the waters of all the important rivers in the state except a few in the S.W. and a few in the extreme E. About 160 m. from its mouth are the Cascade Mountains and makes a descent of about 300 ft. through a canyon 6 m. long and nearly 1 m. deep. The passage of vessels through the river at this point is made possible by means of locks. Fifty-three m. farther up the stream is a second set of rapid rapids which make the river impassable to all but small craft. The tributaries of the Columbia E. of the Cascade Mountains and lying wholly within the state are the John Day river, which rises in the Blue Mountains and enters the Columbia 29 m. above the Dalles after pursuing a binding course of about 200 m.; and the Deschutes river, which rises on the eastern slope of the Cascade Mountains, and after flowing northward for about 320 m. enters the Columbia 12 m. above the Dalles. The Deschutes river drains a region which is less arid than the plateau farther E. and which contains a number of small basaltic calderas. The Columbia river may be said to form the boundary between the Willamette and the Wallowa Country, each with its type of climate and vegetation.

Western Oregon.

The volume of water contained in the rivers of western Oregon is fairly small; the Deschutes and Columbia are the only rivers of importance. The Deschutes has a mean height of flow of 300 ft. and a discharge at the Dalles of about 60,000 ft. at 1908. The Columbia is about 54,000 sq. m. and 5-6% of the land area.

The Federal government established in 1907 and 1908 thirteen forest reserves in the state, ten of which had an area of more than 1,000,000 acres each; their total area on the 1st of January 1910 was 25,345 sq. m. About 12,800 sq. m. of this area is in the Willamette forests.

The Willamette is the state is heavily timbered, except in small prairies and clearings in the Willamette and other valleys, and the most valuable tree is the great Douglas fir, pine or spruce (Pseudotsuga Douglasii), called Oregon pine, which sometimes grows to a height of 300 ft. and which was formerly in great demand for masts and spars of sailing-vessels and for bridge timbers; the Douglas fir grows more commercial timber to the acre than any other American variety, and constitutes about three tenths of the total stand of the state. The Blue Mountains and numerous small mountains in the central and southern parts of the state. East of the Cascades the valleys are usually treeless, save for a few willows and cottonwoods in the vicinity of streams. Over the flat springy prairie that is characteristic of the Willamette valley and by its ubiquity it imparts to the landscape the monotonous greyish tint so characteristic of the arid regions of the western United States. West of the Cascades most of the trees of commercial value are the eastern hardwoods. The western white pine (P. monticola) is the most valuable. There are small amounts of sugar pine, yellow pine, red fir and silver fir (Abies grandis and A. nobilis) and spruce; and among the broad-leaved varieties the oak, maple, mahogany- cattoids, (Oncorhynchus transmontanus) the ocean salmon, or spring salmon, and the Pacific or chinook salmon, (Oncorhynchus tshawytscha), are both excellent food and valuable.

In Southern Oregon, especially in the Great Basin region, there are numerous lakes. Some of the chief mountain lakes in the Klamath and Siskiyou counties are important for their scenic beauty. Near the northwestern boundary of Klamath county is the famous Crater Lake, whose surface is 6239 ft. above the sea. This lake lies in a great pit or caldera created by the wrecking in prehistoric times of the volcano Mount Mazama, which according to geologists once had an altitude of about 1500 m. The Crater Lake is surrounded by the upper portion of the mountain in the inward, possibly owing to the withdrawal of interior lava, and left a crater-like rim, or caldera, rising 2000 ft. above the surrounding country. The lake is 15 m. broad at its widest point, 9 m. above the bed of the caldera, and is surrounded by walls of rock from 500 to 2000 ft. high. In spite of its great elevation the lake has never been known to freeze, and though it has no visible outlet its waters are fresh.

The primary timber region in Oregon is the settled areas, but is still fairly abundant on the plains of the east and among the mountains of the west. In the mountain forests of southwestern Oregon, bear, deer, elk, pumas, wolves and foxes are plentiful. Among the most characteristic of the various species, the antelope (Odocoileus hemionus) and mule and big-horn (mountain sheep), and occasionally a few elk, in the winter. Bears, wolves, lynxes and foxes are also numerous in the east, and there the coyote is found in disagreeable numbers. The pocket-sipher and the jack-rabbit are so numerous as to be greatly exterminated in some of the more southern parts of Oregon and California. Sage-hens are occasionally seen on the dry plateaus and valleys, especially in Harney County. The Oregon robin (Eruta naevia) and the Oregon snowbird (Junco Oreganus) are common in Oregon and northwest. On the rocky headlands and of the coast a great number of gulls, cormorants, puffins, guillemots, surf-ducks (Oidemia), dotterels, terns, petrels and thousands of other birds. There, too, the Steller's sea-lion (Eumetopias stelleri) spends the mating season. The marine fauna is abundant and of great economic importance. The river fauna of the coast is of two distinct types: the type of the Columbia fauna in rivers north of the Rogue; and another type in the Klamath and its tributaries. Typical of the Columbia river is Castatoma macrachinthus and of the Klamath, Alosa ozeana. The Pacific herring (Clupea harengus) — the white sturgeon (Acipenser transmontanus) is commonly known as the "Oregon sturgeon" — trout and salmon are the principal anadromous fish, the salmon and trout being the most important economically. The best variety for the salmon for canning are: the Chinook or king, (Oncorhynchus tschawytscha) better than any other variety; and the steel-head, blue back or sukgek (O. nerka).

The total woodland area of the state according to the United States census was 54,900 sq. m. or 56-8% of the land area.
Basin region, while the mean annual temperature is 54°, the highest
and lowest ever recorded are respectively 104° and −32°. These
records afford a striking illustration of the moderating influence of
the ocean upon climate.
During the winter the Pacific states, the amount of rainfall de-
creases from N. to S., and is greatest on the seaward slopes of the hills
and mountains. As the winds from the ocean are depleted in their
moisture on reaching the Coast and Cascade ranges, the amount of
annual precipitation is from 40 to 80 inches. In the Willamette Val-
ey basin the precipitation averages over 50 inches, and in the valley
of the Columbia, at The Dalles, on the Columbia, 138 inches, con-
stantly diminishes toward the E. until in the extreme south-eastern
part of the state it amounts to only about 8 inches. No other state,
except perhaps Washington, has such a great variation in the amount
of its rainfall. Precipitation on the Coast is over 75 inches, and at
the altitudes above 2000 ft. amounts to about 138 inches annually; in
the valleys E. of this range it varies from 20 to 2 in. at Ashland to
78-2 in. at Portland. On the western slope of the Cascades it varies
from 50 to 2 inches at Frazier's Peak, and in the eastern part of the
state, in the region of the Snake and the Wasatch Ranges, the aver-
age amount is from 10 to 15 inches; in the valleys and foothills of the
Blue Mountains, 12 to 25 inches; and in the plateau region of central
and south-eastern Oregon, 8 to 22 inches. In the region W. of the
Cascade Mountains there is a marked increase in the precipitation.
On the Columbia, from March to October, and the summers are almost rainless. In the rest of
the state there is a maximum rainfall in the winter and a second wet
season in May and June, with the rest of the summer very dry. Dow
the western side of the Cascades winds are 60-80 per cent. of the
moisture; during the summer they are from the N.W. and are
accompanied by cloudless skies and moderate temperatures. Win
from the N.E. bring hot weather in the summer and intense cold in the
winter.
Soils.—The state has almost as great a variety of soils as of climate.
In the Willamette Valley the soils are mostly clay loams, of a basaltic
nature on the foothills and greatly enriched in the river bottom lands
by clay coming down the river. In the Blue Mountains the soils
are so-called loams, made up of volcanic dust and alluvium from the
uplands. They are deep, of fine texture, easily worked and contain abundant plant
food in the form of soluble compounds of calcium, sodium and potassium.
At times, however, they are present in such excess as to render the soil
alkaline or plant growth. While the alkali and the water supply is sufficient, good crops can be grown
in this soil without the use of fertilizers.
Fruit-growing.—Oregon has some of the most
productive agricultural lands in the United States, but they are
rather limited in extent, being confined for the most part to the
valleys west of the Cascade Mountains and the counties bordering on
the Columbia river east of those mountains. The other parts of the
state, especially the lower mountainous area, have the greatest
numbers of cropland, but contain considerable areas suitable for grazing. In
1891 only about one-sixth of the total land surface was included in farms, and
a trifle less than one-third of the farm land was improved. There
were about 16,000 farms, the area under cultivation in 1892, 232,744 acres,
number 33 0% (11,827) contained less than 100 acres each, 30-5% (11,055)
contained from 100 to 175 acres each, and 10-4% (3727), devoted mainly to stock-raising,
contained 500 acres or more each. Nearly 20,000 acres were devoted
to the growing of timber, of which nearly 6000 acres were owned by
the Oregon lumber companies, and nearly 3000 acres were
owned by individuals. The rough lumber in logs was about
30,000,000 feet, chiefly softwood.
Fruit-growing in the Willamette Valley was
founded to be exceedingly favourable to their growth, and the
product increased to 20,500,000 lb in 1895, when the state ranked
first in the Union in this industry.
The agricultural resources of the state may be considerably in-
creased by the encouragement of dry farming and the irrigation of
areas, which are widely distributed, increased from a total of 177,944
acres in 1889 to 388,310 acres in 1902. In 1894 Congress passed the
"Carey Act", which authorizes the Secretary of the Interior, with
the consent of the State of Oregon, to authorize the operation of
the Oregon Irrigation Company, and to accept the lands donated. In
1902, there are Federal desert lands as much of such lands (less than
1,000,000 acres) as the state may apply for, on condition that the
state reclaim by irrigation, cultivation and occupancy not less than
20 acres of each 100-acre tract within the important tracts in the
operation of this Act the state chose 432,203 acres for reclamation,
mostly in the basin of the Deschutes river. Furthermore there is
a state association engaged in irrigation projects, and the United
States has a drain upon the water resources of the Willamette.
In 1898, under the provisions of the "Klamath project, to irrigate
181,000 acres in Klamath county, Oregon (about 150,000 acres) and Siskiyou and Modoc counties,
California, by two canals from Upper Klamath Lake and by a storage
dam at a point where the water is over 100 feet deep. The amount of
water, authorized in 1905 and was 36% completed in 1909. It
has been estimated that the irrigated and irrigable area under private
canals is about 80,000 acres, and that that still unoccupied of in 1909,
authorized by the state under the Carey Act, amounted to 180,000
acres.
Fisheries.—The Columbia river has long been famous for its salmon,
and as the supply seemed threatened with exhaustion for several years, the state in 1883, the state legislature in 1901 passed an act establishing a close season both early in the
migrating and late in the summer and prohibiting any fishing, except
with hook and line, at any time, without a licence. In 1908 two laws
proposed by initiative petition were passed, stopping all fishing by night or in the dark. The salmon of the
river is about 1500 miles long, its length from seines to the
upper river and abolishing the use of any gear by fishermen of the upper river— the mouth of the Sandy
river to the mouth of the Willamette.
Montana county, being the dividing line between the upper and lower Columbia, is under irrigation
by the state authorities of Oregon and Washington and by the Federal government for propagating the best varieties: the Chinooks (O. tshawytscha), the bluebacks (O. nerka) and, when the bluebacks become silver, silver salmon (O. kisutch). The
salmon from the Oregon side of the Columbia river in 1901 was 16,725,435 lb; from this it rose to 24,575,228 lb in 1903, but fell to 18,151,743 lb in 1907 and 14,456,548 lb in 1908. Salmon are caught in smaller quantities in the Oregon section of the river, near the mouth of Willamette, river, and the salmon catch in 1907 was 3,640,486 pounds and in 1908, but only 6,738,628 lb in 1907 and 6,422,511 lb in 1908. Some catfish, shad, smelt, halibut, herring, perch, sturgeon, flounders, oysters, crabs, crawfish are also obtained from Oregon waters.
In the Willamette valley, the streams of S. and the Siletz in Oregon in 1852, and placer-mining was prosecuted here without interruption until 1860, when the metal was found in larger quantities on the streams in Baker and Grant counties in the eastern part of the state. The placer deposits have been
largely taken the place of placer-mining, but the two principal gold-producing districts are still that traversed by the Blue Mountains in the north-eastern quarter and that drained by the Rogue river in the southwest corner, a continuation of the California field. The value of the total output of the state was $2,113,556 in 1894, but only
$865,076 in 1908. Silver is obtained almost wholly in the form of
alloy with gold, and in 1908 the value of the output was only
$2,113,556 in 1894, and in 1908 the output amounted to 1,876,377 lb of copper. Gold ore, lead, quicksilver and cobalt have been obtained in the state in merchantable quantities, and there is some zinc ore in the central and eastern part of the state. There is also marble, sandstone, limestone, also, in Baker, Grant, Wallawa, Jackson
and Josephine counties. Sandstone is abundant, and there is some
granite, in the Coast Range. A variegated marble is obtained in
Douglas county, and other marbles are found in several counties.
Clays suitable for making brick and tile are found in nearly every part of the state: in 1908 the clay products of the state were valued at
$555,785. Soapstone is abundant in both the E. and W. counties.
Ochre, or mineral paint, and mineral waters, too, are widely

---
distributed. There is some roofing slate along the Rogue river, natural asphaltum, nickel, bismuth and wolframite in Douglas county, gymnure in Baker county, fire-clay in Clatsop county, borate of soda on the marsh lands of Harvey county, infusorial earth and triplin in the valley of the Deschutes river, chromate of iron in Curry and Douglas counties, molybdenite in Union county, barite in Curry county, borate of lime in Curry county, manganese ore in Columbia county, and asbestos in several of the southern and eastern counties. The total value of all mineral products in 1908 was $2,743,434.

Manufactures.—Manufacturing is encouraged by both the variety and abundance of raw material furnished by the mines, the forests, the farms and the fisheries, and by the coal and water-power available for operating the machinery. The total value of all the manufactured products increased from $8,652,714 in 1880, to $14,221,747 in 1890, or 279% in ten years, and although progress was slow from 1890 to 1900 there was a rapid advance again from 1900 to 1905, when the value of the factory products increased from $55,525,123 in 1900, to $72,489,908 in 1905. Portland and Astoria are the chief manufacturing centres; in 1905 the value of the factory products of these two cities was 72% of that of the factory products of the entire state.

Transportation and Commerce.—For 110 m. from the mouth of the Columbia river to Portland, 12 m. up the Willamette river, is a channel which in 1909 was navigable (20-22 ft. deep) by large ocean-going vessels. The navigation is regulated by the depth of the river at the time of the completion of the Federal project of 1902. From the mouth of the Willamette river vessels of light draft ascend the Columbia (passing the Cascade Falls through a lock canal, which was opened in 1866 and has a capacity of 85,000 tons) to Walla Walla, and from the mouth of the Snake river (in the state of Washington), up that river to the mouth of the Imnaha, in Walla county, on the eastern boundary of Oregon, and, when the water is high, up the Imnaha river, which drains the western part of the county, to Baker city. The Willamette river is navigable to Harrisburg, 152 m. above Portland, but boats seldom go farther up the river than Corvallis, 119 m. above Portland, and the depth at low water to Corvallis is only 3 ft. On the coast, Coos Bay, a tidal estuary, is the chief channel between Oregon and San Francisco; it admits vessels drawing 14 to 16 ft. of water, and both the north and south forks of the Coos are navigable for vessels of light draft (the depth at low water is 1-1 1/2 ft.) 14 m. from the mouth of the river to Coos bay. Eureka, 8 m. more, and Yaquina Bay and Tillamook Bay also admit small steamboats. The Coquille river is navigable for about 37 m., the Yaquina river for 23 m. with a depth of 13 to 15 ft., the Siuslaw river for 6 m. (for vessels drawing less than 6 ft.), the Clackamas river for 5 m., the Willamette river for 75 m., and the Umpqua river for 25 m. Boats often go as far as Roseburg, 128 m. from the mouth. The Salish and Columbia rivers are used occasionally by steamboats in the summer months. The Oregon railroad was built from the mouth of the Columbia river to Portland in 1855, and the eastern terminus of the line was extended westward to the Oregon-California boundary on the 14th of May 1868, ground was broken for the proposed line on the west side, and two days later it was broken for one on the east side; that on the east side was completed for 20 m. south of Portland in 1869 and that on the west side was completed to the Oregon-California boundary in 1870. The total mileage was 150 m. The principal period of railroad building was from 1880 to 1890, during which 931-97 m. were built and the state’s mileage increased from 508 m. to 1,439-97 m. In 1900 the total mileage was 2,809-46 m. There are 110 rail road companies. The principal railways are: that of the Oregon Railroad & Navigation Company (controlled by the Union Pacific), which crosses the north-eastern corner of the state and then runs along the bank of the Columbia river to Portland; three lines of the Southern Pacific in the Willamette Valley, the main line connecting Portland with San Francisco; the Astoria & Columbia River, connecting Portland and Astoria; the Coos Bay, Roseburg & Eastern Railroad & Navigation Company (owned by the Southern Pacific), connecting Coos Bay and a point one mile beyond Roseburg; the Corvallis & Eastern (owned by the Southern Pacific), connecting Corvallis with the Southern Pacific. Throughout the Cascade Mountain Region and the great semi-ard region east of those mountains, the tracks are laid in such close proximity to each other that more than two-thirds of the state’s area, there is not a railway.

The state carries on an extensive commerce with the Orient and with the Canadian provinces. Its exports are principally lumber, wheat, livestock, coal and fish; its imports are principally the largest part of the Oriental countries. There are four customs districts: southern Oregon, with Coos Bay as the port of entry; Willamette, with Portland as the port of entry; Oregon, with Astoria as the port of entry; and Yaquina, at the mouth of the Yaquina river.

Population.—The population of Oregon in 1850, was 13,294; in 1860, 25,465; in 1870, 90,923; in 1880, 174,768; in 1890, 317,704; in 1900, 413,536; in 1905, 547,716, or an increase of 30-2% in the decade; and 672,765 in 1910, a further increase of 62-7%. Of the total population in 1900, 347,788, or 84-1%, were native-born; 65,748 were foreign-born; 394,582, or 95-4%, were of the white race, and 18,954 were coloured. Of those born within the United States only 164,431, or less than one-half, were native of Oregon, and of those born in other states of the Union 128,654, or about seven-tenths, were natives of one or another of the following states: Missouri, Illinois, Iowa, Ohio, California, New York, Indiana, Kansas, Washington, Wisconsin and Pennsylvania. Nearly three-fourths of the foreign-born were composed of the following: 13,282 Germans, 936 Chinese, 9007 Scandinavians, 7508 Canadians, 5663 English and 4210 Irish. The coloured population consisted of 10,397 Chinese, 4951 Indians, 250 Japanese and 1105 negroes.

The Indians are remnants of a large number of tribes, most of which are aboriginal to this region, and they represent ten or more distinct linguistic races. The chief government schools are: the Clackamas, Cow Creek, Calapooya, Lakmiit, Mary’s River, Molala, Nestucca, Rogue River, Santiam, Shasta, Tumwater, Umpqua, Wasco and Yamhill, numbering 145 in 1905, under the Grande Ronde reservation, in Polk and Yamhill counties; the Klamath (658), Modoc (216), Paiute (103), and Pit River or Achomawi (56), under the Klamath school on the Klamath reservation (1308-8 sq. m.) in Klamath and Lake counties; the Aseka, Coquille, Kusan, Kwatami, Roseburg, Rose, Skokomish, Siuslaw, Tututni, Umpqua and several other small tribes, numbering 442 in 1909, under the Siletz school, on the Siletz reservation (5 sq. m.) in Lincoln county; the Cayuse, Umatilla and Wallawalla, numbering 1260 in 1870 on the Umatilla reservation (124-73 sq. m.) in Umatilla county, and the Paiute, Tenino, Warm Springs and Wasco Indians, numbering 765 in 1909, under the Warm Springs school on the Warm Springs reservation (503-29 sq. m.) in Warm Springs county. The pupils at these schools are engaged in farming and stock-raising, but a few still derive their maintenance mainly from fishing and hunting.

Roman Catholics are the most numerous religious sect in the state (in 1906 out of a total of 120,229 communicants of all religious bodies, they numbered 35,317). The rural population (i.e. population outside of incorporated places) is very sparse, only about 2½ in 1900, to the square mile, and while it increased from 203,973 in 1890 to 220,834 in 1900, or only 11-3% of the urban (i.e. population of places having 4000 inhabitants or more) together with the semi-urban (i.e. population of incorporated places having less than 4000 inhabitants) increased during the same decade from 113,731 to 183,664, or 61-5%. The principal cities are Portland, Astoria, Baker City and Salem, which is the capital.

Administration.—The state is still governed under its original constitution of 1857, with the amendments adopted in 1902, 1906 and 1908. This constitution may be amended: by a majority of the popular vote at a regular general election, if the amendment has been passed by a majority vote of all the elected members of each house of the legislature; or by an initiative petition; or by a constitutional convention, which may not be called, however, unless the law providing for it is approved by popular vote. The right of suffrage is conferred by the constitution upon all white male citizens twenty-one years of age and over who have resided in the state during the six months immediately preceding the election, and upon every white male of the required age who has been a resident of the state for six months, and who, one year before the election, has declared his intention of becoming a citizen and has resided in the United States for five years prior to the election. Idiots, insane persons and persons convicted of serious crimes are disfranchised. The clause excluding negroes and Chinese from the suffrage has never been repealed, although it has been rendered nugatory by the Fifteenth Amendment to the Federal Constitution. Another provision which has been annulled by amendment to the Federal Constitution, but which still remains in the state constitution, is a clause forbidding free negroes or mulattoes, not residing in the state at the time of the adoption of the constitution, to enter the state or to own real estate or make contracts and maintain suits therein, and bidding the legislature provide for the removal of such negroes and mulattoes and for the punishment of persons bringing them into the state, or employing or harbouring them. The constitution provides that no Chinaman, not a resident of the state at the time of
the adoption of the constitution, shall ever hold any real estate or mining claim, or work any mining claim in the state.

The chief executive functions are vested in a governor, who is elected for a term of four years, and who must be at least thirty years old and must have been a resident of the state for three years before his election. He is not eligible to the office for more than eight years in any period of twelve years. He has the right of pardon and a veto of legislative acts, which may be overridden by a two-thirds vote of the members present of each house of the legislature. The other important administrative officers are the secretary of state (who succeeds the governor if he dies or resigns—there is no lieutenant-governor), treasurer, attorney-general, superintendent of public instruction and labour commissioner. No public officer may be impeached, but for sufficient cause the governor may remove a justice of the supreme court or a prosecuting attorney from office, upon a joint resolution of the legislature adopted by a two-thirds vote in each house. A public officer may be tried for incompetence in writing or rendition of a record; no secretary of a regular proceeding in criminal cases, and if convicted he may be dismissed from office and receive such other penalties as the law provides.

The legislative department (officially called "the legislative assembly") consists of a Senate of thirty-four members chosen for four years, with half the membership retiring every two years, and a House of Representatives of sixty-six members elected biennially. A single county distributes its constitutional offices among more than one county or county may be divided between different senatorial districts. The sessions of the legislature are biennial. Bills for raising revenue must originate in the House of Representatives, but the Senate may amend them. Until 1902 the legislature was the sole law-making body in the state, but on the 2nd of June of this year the voters adopted a constitutional amendment which declared that "the people reserve to themselves power to propose laws and amend the constitution, and to reject the same at the polls, independent of the legislative assembly, and also reserve power at their own option to approve or reject at the polls any act of the legislative assembly." This provision for the initiative and referendum was drafted and submitted to the people by a committee appointed in 1903. Eight per cent of the number of voters who at the last preceding election voted for a justice of the supreme court, by filing with the secretary of state a petition for the enactment of any law or constitutional amendment, the people may propose to the legislature the act, or amendment, and it shall be referred to the voters at the next general election; if it receives the approval of a majority of those voting, the act or amendment shall be enacted into law and go into effect from the day of the governor's proclamation announcing the result of the election. A referendum of legislative enactments may be ordered in two ways: the legislature itself may refer any act or amendment to the voters without asking their judgment on the constitution, and to force such regular election, in which case the act may not be vetoed by the governor and does not go into effect until approved at the polls; or 5% of the number of voters at the last election for a supreme court judge on a petition order any act, except such as are "necessary for the immediate preservation of the public peace, health or safety," to be referred to the voters for their approval or rejection. Such a petition must be filed within ninety days after the adjournment of the session in which it is required to mail to every voter whose address he has a pamphlet containing the text of the laws to be voted upon at the ensuing election. Along with the text of the law, the state will print arguments for and against the law, and the cost of the extra printing is paid by the initiators. In like manner, any one who will depurate the expense of the printing may submit arguments in opposition to any proposed measure, and the law as printed shall include the arguments of the people, and the people have the law at its own expense. This "text-book" for the voters contained 30 pages in 1906 and 126 pages in 1908.

The power of the initiative was first exercised by the people of Oregon in 1901, when they proposed and enacted a local option liquor law and a direct primary law. As a result of the initiative, the voters in Oregon, in 1908 nine-tenths of the thirty-three counties of the state had prohibited the sale of intoxicants since 1905. The most important effects of the initiative and referendum law have been to choice of United States senators by what is practically a popular vote. Candidate for United States Senate are voted for in the primaries, and between 1904 and 1906 candidates for those states were required to say whether or not they would support the people's choice for United States senator regardless of their own preferences. In the state election in June 1908 a Democrat received the highest popular vote for the senatorship and as a majority of the legislature of 1909 had committed itself to vote for the people's choice, he was elected by the Senate. Although the choice of Senate of the Democratic initiative in 1909 was a five-to-one issue, but the outcome of the initiative in 1909 was a five-to-one issue, but the outcome of the initiative in 1908 and 1909 were separate measures. This was an anomaly in American politics. In June 1906 five laws and five amendments to the constitution, proposed by initiative petitions, and one law on which the referendum was ordered by the legislature, were submitted to the people. An attempt giving women the right to vote was defeated, and another, the adoption of a providing for the initiative upon special and local laws and parts of laws, and another giving cities and towns the exclusive right to regulate the time and manner of selling liquor to voters, subject only to the constitution and the criminal laws. The laws was thus the first New York state to grant home municipalities to its municipalities. At the election in June 1908 the number of initiative and referendum measures amounted to twelve, and the ballot required forty-one separate marks to be stuffed in the ballot box, which was only one opposed by the people.

The measures to be voted on consisted of eleven laws or constitutional amendments proposed by initiative petition, four constitutional amendments referred to the people by the legislature, and four laws upon which the voters had ordered a referendum. Of the measures defeated were the fourth woman's suffrage amendment voted down in Oregon, a single-tax bill and an "open town" bill designed to defeat the purpose of the local option liquor law. Among the measures adopted was the one by requiring legislators to vote for the people's choice for a United States senator—this was adopted by a vote of 69,688 to 21,162, a corrupt practices act, regulating the expenditure of money in political campaigns; a law providing for proportional representation, i.e., representation for each political party in proportion to its numerical strength, by providing for the first and second choice in voting—the system of preferential voting adopted in New York City in 1895, by which if any candidate for the judges may remove from office after six months' service by a special election any local official.

Judiciary.—The judicial department of the state consists of a supreme court, circuit courts, county courts (held by a country judge in each county) and the courts of local justices of the peace. The supreme court consists of five (before the number was three) justices elected for a term of six years, and its jurisdiction extends only to appeals from the circuit courts, and the decisions of the supreme court are final. The circuit courts were formerly supreme court justices on circuit; they also are chosen for six years, and have cognizance over all cases, including appeals from inferior courts, not specifically provided for by law for some other tribunal. The judges of the circuit courts are elected for four years, and their courts have jurisdiction over probate matters, civil cases involving amounts not exceeding $500, and criminal cases in which the offence is not punishable by death. In such cases the justices of the peace have the jurisdiction of a number of districts or precincts for which there is a justice of the peace, elected biennially and having jurisdiction in minor cases.

Local Government.—For the purposes of local government the state is divided into thirty-four counties. The constitution provides that no county may have an area of less than 400 square miles, and that no new county may be created unless its population is at least 1200. County affairs are administered by the county judge acting with two county judges. The counties and cities and towns may be incorporated as a town or city, and as such possess complete self-government in all purely local matters, even

$Before 1904, under a law of 1901, the people voted for candidates for the United States Senate, but the legislative assembly was in no way required to appoint a candidate. In 1904 the legislature chose as United States senator a candidate for whom no votes had been cast in the popular election.

$It is to be noted that the Republican party had not favored preferential voting for judges, and therefore lost a large number of votes for the direct primary, and in 1904 worked for the choice of the Democratic candidate by the people in the hope that the (Republican) legislature would not ratify the popular choice and so would nullify the direct primary law. The people's choice for Northeast and the people—have come into conflict. In 1906, for example, the people by the initiative secured a law forbidding public officers from accepting free passes from railways. In 1907 the legislature repealed all laws on this subject and required railways to furnish free transportation to certain officials. Upon one measure, however, the people ordered a referendum and it was rejected at the polls. In 1908 the people voted against increasing the number of supreme court judges; in 1909 the legislature increased the number.
having the power to revise its own charter. A constitutional amendment of 1906 forbids the formation of corporations by special laws (formerly the constitution provided that corporations shall not be created by special laws except for municipal purposes)  and says: "The legislature assembly shall not enact, amend or repeal any law pertaining to the management of the state, its finances, contracts, or property, except as to their own municipal legislation; but "not more than 10% of the legal voters may be required to order the referendum nor more than 15% to propose any measure by the initiative, in any city or town.

Local Boards. The value of the homestead exempt from judicial sale for the satisfaction of liabilities is limited to $1500; the homestead must be owned and occupied by some member of the family claiming the exemption and may not exceed in area one block in any city, two acres in any town, or one hundred acres in any rural community. The exemption is not valid against a mortgage, but the mortgage must be executed by both husband and wife, if the householder is married. The debtor claims the exemption where the levy is made, but if the sheriff deems the homesteader greater in value than the law allows he may choose three disinterested persons to appraise it and sell any portion that may be adjudged in excess of the legal limit. The constitution provides that the property and pecuniary rights of every married woman, at the time of her marriage, or afterwards, acquired by gift, devise or inheritance, shall not be subject to the debts or contracts of the husband; and that laws shall be passed providing for the registration of the wife's separate property. Marriages between persons and Indians or persons of mixed blood and Indians, and between first cousins are forbidden or are void. One year's residence is necessary to secure a divorce, for which the causes recognized are a conviction of felony, habitual drunkenness for one year, physical incapacity, desertion for one year and cruelty or procuring an abortion.

Education. — The public school system (organized 1873) is administered by the superintendent of public instruction, who exercises a general supervision over the schools, and by the state board of education, which is constituted by the governor, the secretary of state, and the treasurer, and that the income from it is apportioned among the counties according to the number of school children, and to the assessed value of property in such counties. The legislature provides for a public school for every school district and the sale of magnificent leadville high school, the aggregate annual amount of which shall be equivalent to at least seven dollars for every child between the ages of four and twenty years. If the total annual fund for a school district amounting to $100 or more be deposited in the savings bank, the treasurer shall spend the fund to the extent of $50; if the fund be greater, the amount exceeding $50 shall be deposited in the savings bank, and the expenditure must be apportioned among the schools in the district, except when the school carries on special instruction, and that school district may appropriate the fund up to that sum. Each school district in the state is required to have a school term of six months or more. Special county funds are levied for the maintenance of public school libraries also. For all children between the ages of nine and fourteen inclusive who are not attending school is compulsory.

The total number of teachers in the public schools in 1908 was 4243; the total school enrollment, 107,493; the average daily attendance 94,333. In 1908 there was paid for the support of common schools $7,383,333, of which $4,996,490 was for teachers who taught in rural schools and the number of school principals, $856.7.

The proportion of illiterates is low: in 1900 at the age of ten years or over 3.7% was illiterate; of the male population of the same age 3.9% of the female 2.3% and of the native white population only 0.8% were illiterate.

In addition to the public schools, the state maintains: the University of Oregon at Eugene (q.v.); the State Agricultural College (q.v.); the Oregon State Normal School (q.v.); the Pacific University, at Forest Grove; McMinnville College, (q.v.); the University of Oregon, at the work of exploration. In 1774 Juan Perez sailed up the coast as far as 44° N., and Martin Aguilar, with another vessel of the fleet, reached a point near latitude 43° which he called Cape Blanco and claimed to have discovered there a large river. For the next century and a half Spain again neglected this region, until the fear of English and Russian encroachment caused her to resume the work of exploration. In 1774 Juan Perez sailed up the coast as far as 44° N., and on his return followed the shore line very closely, thus making the first real and undisputed exploration of the Oregon coast of which there is any record. In the following year the Englishman Captain Cook sailed the Endeavor, and discovered a new land which is now called Point Grenville and took formal possession of the country, and later, in 1790, he discovered a bay whose swift currents led him to suspect that he was in the mouth of a large river or strait. In 1787, Jonathan Carver (q.v.) published in London "Travels throughout the Interior Parts of North America," in which the following abbreviation of the examples of the Spanish, he asserted that there was a great river on the western coast, although, so far as is known, no white man had then ever seen such a stream. Whether his declaration was based on stories told by the Indians of the interior, or upon reports of Spanish sailors, or had no basis at all, is not known; its chief importance lies in the fact that Carver called this undiscovered stream the Oregon, and that

1 Some early writers assert that Drake even reached the lat. 1848° N. and anchored in the Straits of Juan de Fuca.
this name was eventually applied to the territory drained by this great western river. The name, like the whole story, may have been of Spanish or Indian origin, or it may have been purely fanciful. The Spaniards made no effort to colonize north-western America or to develop its trade with the Indians, but toward the end of the 18th century the traders of the great British fur companies of the North were gradually pushing overland to the Pacific. Upon the sea, too, the English were not idle. Captain James Cook in March 1778 sighted the coast of Oregon in the lat. of 44°, and examined it between 47° and 48° in the hope of finding the Straits of Juan de Fuca described in Spanish accounts. Soon after the close of the War of Independence American merchants began to buy furs along the north-west coast and to ship them to China to be exchanged for the products of the East. It was in the prosecution of this trade that Captain Robert Gray (1755-1806), an American in the service of Boston merchants, discovered in 1792 the long-sought river of the West, which he named the Columbia, after his ship. By the discovery of this stream Gray gave to the United States a claim to the whole territory drained by its waters. Other explorers had searched in vain for this river. Cook had sailed by without sight of it; Captain John Meares (c. 1756-1809), another English navigator, who visited the region in 1788, declared that no such river existed, and actually called its estuary “Deception Bay”; and George Vancouver, who visited the coast in 1792, was sceptical until he learned of Gray’s discovery.

Spanish claims to this part of North America did not long remain undisputed by England and the United States. By the Nootka Convention of 1790 Spain acknowledged the right of English subjects to fish, trade and settle in the parts of the northern Pacific coast not already occupied; and under the treaty of 1819 (proclaimed in 1821) she ceded to the United States all the territory claimed by her N. of 42°. But even before these agreements had been reached, Alexander Mackenzie, in the service of the North-west Company, in 1793 had explored through Canada to the Pacific coast in lat. about 52° 26′ N., and Meriwether Lewis and William Clark, American explorers acting under the orders of President Jefferson, in 1803-1806 had passed west of the Rocky Mountains and down the Columbia river to the Pacific Ocean. Both Briton and American adventurers were attracted to the region by the profitable fur trade. In 1808 the North-west Company had several posts on the Fraser river, and in the same year the American Fur Company was organized by John Jacob Astor, who was planning to build up a trade in the West. In 1811 the Pacific Fur Company, a kind of western division of the American Fur Company, founded a trading post at the mouth of the Columbia which they called Astoria, and set up a number of minor posts on the Willamette, Spokane and Okanagon rivers. On hearing of the war between England and the United States, Astor’s associates, deeming Astoria untenable, sold the property in October 1813 to the North-west Company. In the following month a British ship arrived, and its captain took formal possession of the post and renamed it Fort George.

Soon after the restoration of peace between England and the United States by the treaty of Ghent (1814), there arose the so-called “Oregon question” or “North-western boundary dispute,” which agitated both countries for more than a generation and almost led to another war. As that treaty had stipulated that all territory captured during the war should be restored to its former owner, the American government in 1817 took steps to reoccupy the Columbia Valley. The British government at first protested, on the ground that Astoria was not captured territory, but finally surrendered the post to the United States in 1818. The United States was willing at the time to extend the north-western boundary along the forty-ninth parallel from the Lake of the Woods to the Pacific, but to this the British government would not consent; and on the 20th of October 1818 both nations agreed to a convention providing for the “joint occupation” for ten years of the country “on the north-west coast of America, westward of the Stony [Rocky] Mountains.” In the following year, as already stated, Spain waived her claim to the territory north of 42° in favour of the United States. In 1821, however, Russia asserted her claim to all lands as far south as the fifty-first parallel. Against this claim both England and the United States protested, and in 1824 the United States and Russia concluded a treaty by which Russia agreed to make no settlements south of 54° 40′, and the United States agreed to make none north of that line. From this time until the final settlement of the controversy the Americans were disposed to believe that their title was clear to all the territory south of the Russian possessions; that is, to all the region west of the Rocky Mountains and north of 40′ south latitude. In 1827 the agreement of 1818 between Great Britain and the United States was declared to be inoperative, and occupation was renewed for an indefinite term, with the proviso that it might be terminated by either party on twelve months’ notice.

For the next two decades the history of Oregon is concerned mainly with the British fur traders and the American immigrants. The Hudson’s Bay Company absorbed its rival, the North-west Company, in 1821, and thus secured a practical monopoly of the fur trade of the North and West. Its policy was to discourage colonization so as to maintain the territory in which it operated as a vast game preserve. Fortunately for the Americans, however, the company in 1824 sent to the Columbia river as its chief factor and governor west of the Rocky Mountains Dr. John McLoughlin (1784-1857), who ruled the region with an iron hand, but with a benevolent purpose, for twenty-two years. On the northern bank of the Columbia in 1824-1825 he built Fort Vancouver, which became a port for ocean vessels and a great entrepôt for the western fur trade; in 1829 he began the settlement of Oregon City; and, most important of all, he extended a hearty welcome to all settlers and aided them in every way in advancing the company’s interests.

In 1832 four Indian chiefs from the Oregon country journeyed to St Louis to obtain a copy of the white man’s Bible; and this incident aroused the missionary zeal of the religious denominations. In 1834 Jason Lee (d. 1845) and his nephew, Daniel Lee, went to Oregon as Methodist missionaries, and with McLoughlin’s assistance they established missions in the Willamette valley. Samuel Parker went as a Presbyterian missionary in 1835, and was followed in the next year by Marcus Whitman and Henry H. Spalding (c. 1801-1874), who were accompanied by their wives, the first white women, it is said, to cross the American continent. Whitman settled at Wai-iat-lu, about 5 m. W. of the present Walla Walla and 23 m. from the Hudson’s Bay Company’s Fort Walla Walla; and Spalding at Lapwai, near the present Lewiston, Idaho. Roman Catholic missions were established near Fort Walla Walla in 1838. In this year Jason Lee returned to the Eastern states and carried back to Oregon with him by sea over fifty people, missionaries and their families. It is significant, if true, that part of the money for chartering his vessel was supplied from the secret reserves fund of the United States.

As early as 1841 the Americans in Oregon began to feel the need of some form of civil government, as the regulations of the Hudson’s Bay Company were the only laws then known to the country. After several ineffectual attempts a provisional government was finally organized by two meetings at Champoeg (in what is now Marion county, north-east of Salem) on the 2nd of May and on the 5th of July 1843. The governing body was at first an executive committee of three citizens, but in 1845 this committee was abolished and a governor was chosen. In
the "fundamental laws" of the provisional government were incorporated a number of Articles from the Ordinance of 1787, and these proved very effective in regulating the government and prohibiting slavery. The new government encountered the opposition of the missionaries and of the non-American population, but it was soon strengthened by the "Great Immigration" in 1843, when nearly nine hundred men, women and children, after assembling at Independence, Missouri, crossed the plains in a body and settled in the Columbia Valley. After this year the flow of immigrants steadily increased, about 1400 arriving in 1844, and 3000 in 1845. Signs of hostility to the Hudson's Bay Company now began to appear among the American population, and in 1845 the provisional government sought to extend its jurisdiction north of the Columbia river, where the Americans had hitherto refrained from settling. A compromise was finally reached, whereby the company was to be exempt from taxes on all its property except the goods sold to settlers, and the officers and employees of the company and all the British residents were to become subject to the provisional government. Meanwhile the western states had inaugurated a movement in favour of the immediate and definite settlement of the Oregon question, with the result that the Democratic party in the House of Representatives of the United States to "the whole of the territory of Oregon" was "clear and unquestionable," and the party made "Fifty-four forty or fight," a campaign slogan. The Democrats were successful at the polls, and President Polk in his inaugural address asserted the claim of the United States to all of Oregon in terms suggesting the possibility of war. Negotiations, however, resulted in a treaty, drafted by James Buchanan, the American Secretary of State, and Richard Pakenham, the British envoy, which the president in June 1846 submitted to the Senate for its opinion and which he was advised to accept. By this instrument the northern boundary of Oregon was fixed at the forty-ninth parallel, extending westward from the crest of the Rocky Mountains to the middle of the channel separating Vancouver's Island from the mainland, and thence southerly through the middle of the said channel, and of Fuca's Straits, to the Pacific Ocean.

Although President Polk immediately urged the formation of a territorial government for Oregon, the bill introduced for this purpose was held up in the Senate on account of the opposition of Southern leaders, who were looking to maintain the abstract principle that slavery could not be constitutionally prohibited in any territory of the United States, although they had no hope of Oregon ever becoming slave territory. Indian outbreaks, however, which began in 1847, compelled Congress to take measures for the defence of the inhabitants, and on the 14th of August 1848 a bill was enacted providing a territorial government. As then constituted, the Territory embraced the whole area to which the title of the United States had been confirmed by the treaty of 1846, and included the present states of Oregon, Washington and Idaho, and parts of Wyoming and Montana. Its area was reduced in 1853 by the creation of the Territory of Washington. The discovery of gold in California drew many Oregon settlers to that country in 1848-50, but this exodus was soon offset as a result of the enactment by Congress in 1850 of the "land donation law," by which settlers in Oregon between 1850 and 1853 were entitled to large tracts of land free of cost. The number of claims registered under this act was over eight thousand.

In 1856 the people voted for statehood; and in June 1857 they elected members of a constitutional convention which drafted a constitution at Salem in August and September 1857: the constitution was ratified by popular vote in November 1857; and on the 14th of February 1859 Oregon was admitted into the Union with its present boundaries. The new state was at first Democratic in politics, and for the southern faction of the Democratic party in 1860 made a bid for its support by nominating as their candidate for vice-president, on the ticket with John C. Breckinridge, Joseph Lane (1807-1881), then a senator from Oregon and previously its territorial governor. The Douglas Democrats and the Republicans, however, worked together as a union party, and Lincoln carried the state by a small majority. The so-called union party broke up after the Civil War, and by 1870 the Democrats were strong enough to prevent the ratification by Oregon of the Fifteenth Amendment to the Federal Constitution. In 1876, after the presidential election, two sets of electoral returns were forwarded from Oregon, one showing the choice of three Republican electors, and the other (signed by the governor, who was a Democrat) showing the election of two Republicans and one Democrat. The popular vote was admitted for the three Republican electors, but one of the Republican electors (Watts) was a deputy-postmaster and so seemed ineligible under the constitutional provision that "no person holding an office of trust or profit under the United States shall be a candidate." Watts resigned, and the secretary of state of Oregon, whose carrying the electoral vote was the canvassing officer, certified the election of the three Republican electors. On the 6th of December the three met, Watts resigned, and was immediately reappointed by the other two. The Democratic claimant, with whom the two Republican electors whose election was conceded, refused to meet, met, alone, appointed two other Democrats to fill the two "vacancies," and the "electoral college" of the state so constituted forthwith cast two votes for Hayes and one for Tilden. The Electoral Commission decided that the three votes should be counted for Hayes—if the one Democratic elector had been adjudged chosen, the Democratic candidate for the presidency, S. J. Tilden, would have been elected. The political complexion of the state has generally been Republican, although the contests between the two leading parties have often been very close. The Indian outbreaks which began in 1847 continued with occasional periods of quiet for nearly a generation, until most of the Indians were either killed or placed on reservations. The Indians were very active during the Civil War, when the regular troops were withdrawn for service in the eastern states, and Oregon's volunteers from 1861 to 1865 were needed for home defence. The most noted Indian conflicts within the state have been the Modoc War (1864-72) and the Shoshone War (1866-68). During the Spanish-American War Oregon furnished a regiment of volunteers which served in the Philippines.

GOVERNORS OF OREGON

Under the Provisional Government.

George Abernethy ... 1843-1849

Joseph Lane ... 1849-1850

Knitting Pritchett (acting) ... 1850

John P. Gaines ... 1850-1852

Joseph Lane ... 1853

George Law Curry (acting) ... 1853

John W. Davis ... 1853-1854

George Law Curry ... 1854-1859

Under the Territorial Government.

John Whiteaker, Dem. ... 1850-1852

Addison Crandall Gibbs, Rep. ... 1852-1866

George Lemuel Woods, Rep. ... 1866-1870

La Fayette Grover, Dem. ... 1870-1877

Stephen Fowler Chadwick (acting) ... 1877-1878

William Wallace Thayer, Dem. ... 1878-1882

Zenas Ferry Moody, Rep. ... 1882-1887

Sylvester Penoyer, Dem. ... 1887-1895

William Paine Lord, Dem. ... 1895-1899

Theodore Thurston Geer, Rep. ... 1899-1903

George Earle Chamberlain, Dem. ... 1903-1909

Frank W. Benson, Rep. ... 1909-1911

Under the State Government.

Oswald West, Dem. ... 1911-
OREGON CITY—OREL

OREGON CITY, a city and the county-seat of Clackamas county, Oregon, U.S.A., on the E. bank of the Willamette river, and S. of the mouth of the Clackamas river, about 15 m. S. by E. of Portland. Pop. (1890) 3062; (1900) 3404 (553 being foreign-born; (1910) 4287. It is served by the Southern Pacific railway, by an electric line to Portland, by other electric lines, and by small river steamboats. The principal business streets are Main Street, on level ground along the river, and Seventh Street, on a bluff which rises abruptly 100 ft. above the river and is reached by four stairways elevated above the tracks of the Southern Pacific railway in the for the most part on this bluff, which commands views of the peaks of the Cascade Mountains. The river here makes a picturesque plunge of about 40 ft. over a basalt ridge extending across the valley, and then flows between nearly vertical walls of solid rock 20-50 ft. high; it is spanned by a suspension bridge nearly 100 ft. above the water. A lock canal enables vessels to pass the falls. The water-power works woolen-mills, flour-mills, paper-mills, and an electric power plant (of the Portland Railway, Light and Power Company), which lights the city of Portland and transmits power to that city for street railways and factories. The municipality owns the waterworks. Next to Astoria, Oregon City is the oldest settlement in the state. In 1829 Dr John McLoughlin (1781-1857), chief agent of the Hudson's Bay Company, established a claim to the water-power at the Falls of the Willamette and to land where Oregon City now stands, and began the erection of a mill and several houses. After 1840, in which year Mr. Loughlin died on a visit to the coast, the Oregon Provision Company, under McLoughlin's son, disputed his claim. He aided many destitute American immigrants, left the service of the company, and removed to Oregon City. In 1850 Congress gave a great part of his claim to Oregon City for the endowment of a university, and in 1852 the legislature of Oregon reconveyed the land to McLoughlin's heirs on condition that they should give $1000 to the university fund; but the questionable title between 1840 and 1862 hindered the growth of the place, which was chartered as a city in 1850.

*O'Reilly, John Boyle* (1844-1890), Irish-American politician and journalist, was born near Drogheda on the 28th of June 1844, the son of a schoolmaster. After some years of newspaper experience, first as compositor, then as reporter, during which he became an ardent revolutionist and joined the Fenian organization known as the Irish Republican Brotherhood, he enlisted in a British cavalry regiment with the purpose of winning over the troops to the revolutionary cause (1863). At this period wholesale corruption of the army, in which there was a very large percentage of Irishmen, was a strong feature in the Fenian rebellion, and O'Reilly, who soon became a great favourite, was successful in disseminating disaffection in his regiment. In 1866 the extent of the sedition in the regiments in Ireland was discovered by the authorities. O'Reilly was arrested at Dublin, where his regiment was then quartered, tried by court-martial for concealing his knowledge of an impending mutiny, and sentenced to be shot, but the sentence was subsequently commuted to twenty years' penal servitude. After confinement in various English prisons, he was transported in 1867 to Bunbury, Western Australia. In 1869 he escaped to the United States, and settled in Boston, where he became editor of The Pilot, a Roman Catholic newspaper. He subsequently organized the expedition which rescued all the Irish military political prisoners from the Western Australia convict establishments (1876), and he aided and abetted the American propaganda in favour of Irish nationalism. O'Reilly died in Hull, Mass., on the 19th of August 1890. His reputation in America naturally differed very much from what it was in England, towards whom he was uniformly mischievous. He was also selected to write occasional odes in commemoration of many American celebrations.

See J. J. Roche, *Life of John Boyle O'Reilly,* (Boston, 1891).

ORL, a government of central Russia, bounded by the governments of Smolensk, Kaluga and Tula on the N., and by Voronezh and Kursk on the S., with an area of 18,036 sq. m. The surface is an undulating plateau sloping gently towards the west; the highest hills barely exceed 900 ft., and none of the valleys is less than 450 ft. above the sea. The principal rivers are the Don, which forms part of the eastern boundary, and its tributary the Soensa; the Oka, which rises in the district of Orel and receives the navigable Zusha; and the Desna, with the Borba, draining the marshy lowlands in the west. Geologically Orel consists principally of Lower Devonian limestones, marls and sandstones, covered with Jurassic clays, the last appearing at the surface, however, only as isolated islands, or in the valleys, being concealed for the most part under thick beds of Cretaceous chalk, marls and sands. The Carboniferous limestones and clays (of the so-called Moscow basin) show in the north-west only at a great depth. The Jurassic clays and marls are over lain at several places with a stratum of clay containing good iron-ore, while the Devonian sandstones and limestones are worked for building purposes. The whole is buried under a bed, 30 to 40 ft. thick, of boulder-clay and loess, the last covering extensive areas as well as the valleys. The soil—a mixture of "black earth" with clay—is fertile, except in the Desna region in the west, where sands and tenacious clays predominate. On the Oka, Zusha, Desna and Borba there is a brisk traffic in corn, oil, hemp, timber, metal, glass, china, paper and building-stone. Marshes occupy large areas in the basin of the Desna, as also in several parts of that of the Oka; they are the principal watercourses, which drain the extensive western area in the districts of Bryansk, Trubchevsk and Karachov, while towards the east, in the basin of the Don, wood is so scarce that straw is used for fuel. The climate is moderate, the average yearly temperature at Orel being 41° in January and 67° in July.

The estimated population in 1906 was 2,365,700. It consists almost exclusively of Great Russians, belonging to the Orthodox Greek Church; the Nonconformists are reckoned at about 12,000, the Roman Catholics at 3000 and the Jews at 1000. The chief occupation is agriculture, which is most productive in the east and towards the centre of the government. The principal crops are rye, oats, barley, wheat, hemp, potatoes, hops, vegetables, tobacco and fruit. Of the grain not used in the distilleries a large proportion is exported to the Baltic. Hemp and hemp-seed oil are extensively exported from the west to Riga, Libau and St. Petersburg. Tobacco is cultivated with profit. Cattle and horse-breeding flourishes better than in the...
neighbouring governments—the Orel breeds of both carriage and draught horses being held in estimation throughout Russia. Bee-keeping is widely diffused in the forest districts, as are also the timber-trade and the preparation of tar and pitch. Manufactures are rapidly increasing; they produce cast-iron rails, machinery, locomotive engines and railway wagons, glass, hemp-yarn and ropes, leather, timber, soap, tobacco and chemical produce. There are also distilleries and a great many smaller oil-works and flour-mills. Karachev and Syevsk are important centres for hemp-carding; Bolkhov and Elets are the chief centres of the tanning industry; while the districts of Elets, Dmitrov and partly Mtsensk supply flour and various food-pastes. At Bryansk there is a government cannon-foundry. The "Maltsov work" in the district of Bryansk are an industrial colony (20,000), comprising several iron, machinery, glass and rope works, where thousands of peasants find temporary or permanent employment; they have their own technical school, employ engineers of their own training, and have their own narrow-gauge railways and telegraphs, both managed by boys of the technical school. Numerous petty trades are carried on by the peasants, along with agriculture. The government is divided into twelve districts, of which the capital towns are Orel, the capital, the trans-Bug districts of Elets, Kargopol, Kratki, Livny, Malo-archangelmsk, Mtsensk, Syevsk and Trubchevsk.

In the 19th century the country was inhabited by the Slav tribes of the Syeveryans on the Desna and the Vyatichis on the Oka, who both paid tribute to the Khazars. The Syeveryans recognised the rule of the princes of the Rurik family from 884, and the Vyatichis from the middle of the 10th century; but the two peoples followed different historical lines, the former being absorbed into the Suzdal principality, while the latter fell under the rule of that of Chernigov. In the 11th century both had wealthy towns and villages; during the Mongol invasion of 1239-1242 these were all burned and pillaged, and the entire territory devastated. With the decay of the Great Horde of the Mongols the western part of the country fell under Lithuanian rule, and was the object of repeated struggles between Lithuania and Moscow. In the 16th century the Russians began to erect new forts and fortify the old towns, and the territory was rapidly colonized by immigrants from the north. In 1610 the towns of the present government of Orel (then known as the "Ukrayna Ukraina") belonged to the Tatar town of Semyon Kamen. In 1617 he led an insurrection against Moscow under the false Demetrios, and suffered much from the civil war which ensued. They continued, however, to be united with the rest of Russia.

(1) The name, "Orel," is of Slavonic origin, and is derived from the practice of the people of placing a great bird or dovecote on the top of towers as a sign of the place. The dovecote was considered a place of honour and protection, and was often erected on a hill or a high point.

Several other volumes of a similar type dealing in a like spirit with Scotland, America, and France followed. He married an Englishwoman, who translated his books. But the main work of the years between 1890 and 1900 was lecturing. Max Orell was a ready and amusing speaker, and his easy manner and his humorous gift made him very successful on the platform. He lectured often in the United Kingdom and still more often in America. He died in Paris, where he was acting as correspondent of the New York Journal, on the 25th of May 1903.

ORELLI, HANS KONRAD VON (1846- ), Swiss theologian, was born at Zürich on the 25th of January 1846 and was educated at Lausanne, Zürich and Erlangen. He also visited Tübingen for theology and Leipzig for oriental languages. In 1860 he was appointed preacher at the orphan house, Zürich, and in 1871 Privatdozent at the university. In 1873 he went to Basel as professor extraordinarius of theology, becoming ordinary professor in 1881. His chief work is on the Old Testament; in addition to commentaries on Isaiah, Jeremiah (1886), Ezekiel and the Twelve Prophets (1888), most of which have been translated, he wrote Die alttestamentliche Weissagung von der Vollendung des Gottesreiches (Vienna, 1882; Eng. trans. Edinburgh, 1885). Die israelitischen Lieder (Basel, 1889), and a journal of Palestinian travel, Durchs Heilige Land (1883). He was a prominent figure in the foundation of the modern Hebrew Semitic language, and his translation of the Bible in Hebrew (1880) is now widely used.

ORELLI, JOHANN CASPAR VON (1787-1840), Swiss classical scholar, was born at Zürich on the 13th of February 1787. He belonged to a distinguished Italian family, which had taken refuge in Switzerland at the time of the Reformation. His cousin, JOHANN CONRAD Orelli (1770-1826), was the author of several works in the department of later Greek literature. From 1807 to 1814 Orelli worked as preacher in the reformed community of Bergamo, where he acquired the taste for Italian literature which led to the publication of Contributions to the History of Italian Poetry (1810) and a biography (1812) of Vittorino da Feltre, his ideal of a teacher. In 1814 he became teacher of modern languages and history at the cantonal school at Chur (Coire); in 1810, professor of eloquence and hermeneutics at the Carolinum in Zürich, and in 1833 professor at the new university, the foundation of which was largely due to his efforts. His attention during this period was mainly devoted to classical literature and antiquities. He had already published (1814) an edition, with critical notes and commentary, of the Antidosis (Book of Imitations) of Quintus Ennodius. The MSS in the Wurtembergische, Wiener, and Ambrosian libraries, which had been made known by Andreas Mystoxedes of Corfu. The three works upon which his reputation rests are the following.

1. A complete edition of Cicero in seven volumes (1826-1838). The first four volumes contained the text (new ed., 1845-1863), the fifth the Old Scholiasts, the remaining three (called Onomasticon Tullianum) a life of Cicero, a bibliography of previous editions, indexes of geographical and historical names, laws and legal formulae, of Greek words, and the consular annals. After his death, the revised edition of the text was completed by J. G. Bailer and C. Halm, and contained numerous emendations by Theodor Mommsen and J. N. Madvig. (2) The Works of Horace (1837-1838; 4th ed., 1886-1892). The excetional commentary, although confessedly only a compilation from the works of earlier commentators, shows great taste and extensive learning, although hardly up to the exacting standard of modern criticism. (3) Inscriptionum Latinarum Selectarum Collectio (1838; revised edition by W. Henzen, 1856), extremely helpful for the study of Roman law, and private life and religion. His editions of Plato (1850-1841) introduced the old scholia, in collaboration with A. W. Winckelmann and Tacitus (1846-1848, new ed. by various scholars, 1875-1894) also deserve mention. Orelli died at Zürich on the 6th of January 1849. He was a most liberal-minded man, both in politics and religion, an enthusiastic supporter of popular education and a most inspiring teacher. He took great interest in the struggle of the Greeks for independence, and strongly favoured the appointment of the notorious J. F. Strauss to the chair of dogmatic theology at Zürich, which led to the disturbance of the 6th of September 1839 and the fall of the liberal government.
ORENBURG—ORENSE

See Life by his younger brother Conrad in Neujahrblatt der Stadtbibliothek Zürich (1851); J. Adert, Essai sur la Vie et les Travaux de J.C.O. (Geneva, 1849); H. Schweizer-Südler, Gedächtnisrede auf J.C.O. (Zürich, 1874); C. Burian, Geschichte der klassischen Philologie in Deutschland (1883).

ORENBURG, a government of south-eastern Russia, bounded N. by the governments of Ufa and Perm, E. by Tobolsk, S.E. by Turgai, and W. by Uralsk and Samara, with an area of 73,704 sq. m. Situated at the southern extremity of the Urals and extending to the north-east on their eastern slope, Orenburg consists of a hilly tract bounded on both sides by steppes. The central ridge occasionally reaches an elevation of 900 ft.; there are several parallel ridges, which, however, nowhere exceed 2000 ft., and gradually sink towards the south. A great variety of geological formations are represented within the government, which is rich in minerals. Diorites and granites enter from the north and crop out at many places from underneath the Silurian and Devonian deposits. The Carboniferous limestones and sandstones, as well as slates Permain, Jurasssic and Cretaceous deposits, have a wide extension in the south and east. Coal has been found on the Miyas (in N.) and near Iletske (in S.). The extremely rich layers of rock salt at Iletske yield about 24,000 tons every year. Very fertile “black earth” covers wide areas around the Urals. The government is traversed from north to south by the Ural river, which also forms its southern boundary; tributaries are the Sibiram and the Ileki. The upper courses of the Uralaya and Samara, tributaries of the Kama and the Volga, also lie within the government, as well as affluents of the Tobol on the eastern slope of the Ural range. Numerous salt lakes occur in the district of Chelyabinsk; but several parts of the flat lands occasionally suffer from want of water. Sixteen per cent of the surface is under wood. The climate is continental and dry, the average temperature at Orenburg being 37°-4° Fahr. (4°-5° in January, 69°-8° in July); frosts of -33° and heats of 98° are quite uncommon.

The estimated population in 1906 was 1,836,500, mainly Great Russians, with Bashkirs and Meshcheryaks (25%). Gold is extracted chiefly from alluvial deposits, about 116,500 oz. every year; also some silver. Nearly one-fifth of all the copper ore extracted in Russia comes from Orenburg (about 16,000 tons annually); and every year 16,000 to 20,000 tons of cast iron and 15,000 tons of iron are obtained. Agriculture is carried on on a large scale, the principal crops being wheat, rye, oats, barley and potatoes. Horses, cattle and sheep are kept in large numbers, and camels are bred. Kitchen-gardening gives occupation to nearly 11,000 persons. Various kinds of animal produce are largely exported, and by knitting and weaving Orenburg ship’s “wool” of goats’ wool is sold at 40,000,000 rubles every year. The growth of the industries is slow, but trade, especially with the Kirghiz, is prosperous. The chief towns of the five districts into which the government is divided are Orenburg, Orsk, Chelyabinsk, Troitsk and Verkhne-Uralsk.

The government of Orenburg was formerly inhabited by the Kirghiz in the south, and by the Bashkirs in the north. The latter were brought under the rule of Russia in 1557, and a few years later the fort of Ufa was erected in order to protect them against the raids of the Kirghiz. The frequent risings of the Bashkirs, and the continuous attacks of the Kirghiz, led the Russian government in the 18th century to erect a line of forts and blockhouses on the Ural and Sibiram rivers, and these were afterwards extended south-westwards towards the Caspian, and eastwards towards Omsk. The central point of these military lines was the fort of Orenburg, originally founded in 1735 at the confluence (now Orsk) of the Or with the Ural, and removed in 1749-1743 120 m. lower down the Ural river to its present site. In 1775 it was besieged by Pugachev, the leader of the revolt of the peasantry.

ORENBURG, a town of Russia, capital of the government of the same name, on the Ural river; connected by rail with Samara (262 m.), and since 1805 with Tashkent (1150 m.). Pop. (1900) 65,006, of whom about 30% were Tatars, Jews, Bashkirs, &c. The town now includes the former suburbs of Golubinaya and Novaya. It is an episcopal see of the Orthodox Greek Church and the headquarters of the hetman of the Orenburg Cossacks. To a barrack house, 3 m. from the town, the camel caravans bring carpets, silks, cottons, lambskins, dried fruits, &c., from Bokhara, Kiva, Kokarz and Tashkent, to be bartered against the textiles, metals, goods, sugar and manufactured wares of Russia. From 20,000 to 100,000 horses, 40,000 to 160,000 cattle, and 450,000 to 750,000 sheep are sold every year at the barrack house. Formerly most of these were sent alive to Russia; now some 200,000 head of cattle and sheep are killed every year, and exported in cold-storage wagons. Cattle are also bought by wandering merchants in the Steppe provinces and Turkestan. Every year many tons of tallow, hams, sausages, butter, cheese and game are exported by rail to Samara. Besides these, nearly a million hides and sheepskins, goat and astrakan skins, as well as wool, horsehair, bristles, down, horns, bones, &c., are exported. There are two cadet corps, a theological seminary, seminaries for Russian and Kirghiz teachers, a museum, branches of the Russian Geographical Society and the Gardening Society, and a military arsenal.

ORENDEL, a Middle High German poem, of no great literary merit, dating from the close of the 12th century. The story is associated with the town of Treves (Trier), where the poem was probably written. The introduction narrates the story of the Holy Coat, which, after many adventures, is swallowed by a whale. It is said that Orendel, son of King Elige of Treves, who had embarked with two ships in order to recapture the lovely Brida, the mistress of the Holy Sepulchre, as his wife. Suffering shipwreck, he falls into the hands of the fisherman Eise, and in his service catches the whale that has swallowed the Holy Coat. The coat has the property of rendering the wearer proof against wounds, and Orendel successfully overcomes innumerable perils and eventually wins Brida for his wife. A message brought by an angel summons both back to Treves, where Orendel meets with many adventures and at last disposés of the Holy Coat by placing it in a stone sarcophagus. Another angel announces both his and Brida’s approaching death, when they renounce the world and prepare for the end.

The poem exists in a single manuscript of the 15th century, and in one print, dated 1512. It has been edited by von der Hagen (1844), L. Etntmiller (1853) and A. F. Berger (1858); there is a modern German translation by K. Simroch (1865); see H. L. Gieseking, Untersuchungen über das Spielmannssgedicht (1879); F. Vogt, in the Zeitschrift für deutsche Philologie, vol. xii. (1890); R. Heinzel, Über das Gedicht vom König Orendel (1892); and K. Müllenhoff, in Deutsche Altertumskunde, vol. i. (2d ed., 1890), pp. 32 sqq.

ORENSE, an inland province of north-western Spain, formed in 1833 of districts previously included in Galicia, and bounded on the N. by Pontevedra and Lugo, E. by Leon and Zamora, S. by Portugal, and W. by Portugal and Pontevedra. Pop. (1900) 904,311; area 2604 sq. m. The surface of the province is almost everywhere mountainous. Its western half is traversed in a south-western direction by the river Miño (Portuguese Minho), which flows through Portugal to the Atlantic; the Sill, a left-hand tributary of the Miño, waters the north-eastern districts; and the Limia rises in the central mountains and flows west-south-west, reaching the sea at the Portuguese port of Viana do Castello. The upper valley of the Limia is the only large tract of level country. The climate is very varied, mild in some valleys, cold and damp in the highlands, rainy near the northern border, and subject to rapid changes of temperature. The railway from Monforte to Vigo runs through the province. There are a few iron foundries of a primitive sort, but lack of transport and of cheap coal hinder the growth of mining and manufactures.

Though the soil is fertile and well watered, agricultural products are not so important as arboriculture. The oak, beech, pine, chestnut, walnut and plane grow in abundance on the hills and mountains; pears, apples, cherries, almonds, figs, roses and olives in the valleys, and even oranges and lemons in sheltered spots. The chief towns are the capital, Orense, Allariz, Carballedo, Viana, Nogueira de Ramuín, Boborós, Cartella and La Vega. See also GALICIA.
ORENSE, an episcopal see and the capital of the Spanish province of Orense; on the left bank of the river Miño, and on the Tuy-Monforte railway. Pop. (1900) 15,934. The river is here crossed by a bridge—"Bridge of seven angles," 110 ft. in length, and at its highest point 132 ft. above the bed of the river. This bridge was built by Bishop Lorenzo in 1230, but has frequently been repaired. The Gothic cathedral, also dating from Bishop Lorenzo's time, is a comparatively small building, but has an image, El Santo Cristo, which was brought from Cape Finisterre in 1330 and is celebrated throughout Galicia for its miraculous powers. The city contains many schools, a public library and a theatre. In the older streets there are some interesting medieval houses. Chocolate and leather are manufactured, and there are sawmills, flour-mills and iron foundries. The three warm springs to the west, known as Las Burgas, attract many summer visitors; the waters were well known to the Romans, as their ancient name, Aquae Originis, Aquae Urenteis, or perhaps Aquae Sylvanis, clearly indicates.

The Romans named Orense Aurium, probably from the alluvial gold found in the Miño valley. The bishopric, founded in the 5th century by the Visigoths, was named the Sedes Auriensis (see Oureum), and from this the modern Orense is derived. The city became the capital of the Suevi in the 6th century; it was sacked by the Moors in 716, and rebuilt only in 832.

OREODON (i.e. "hill-crowned"), the name of an Oligocene genus of North American primitive ruminants related to the camels, and typifying the family Oredontidae. Typical oredonts were long-tailed, four-toed, partially plantigrade ruminants with sharp-crowned crescentic molars, of which the upper ones carry four cusps, and the first lower premolar canine-like both in shape and function.

In the type genus there are forty-four teeth, forming an uninterrupted series. The vertebral artery pierces the neck-vertebrae in the normal manner. The name Oreodon is preoccupied by Orodus, the designation of a genus of Palaeozoic fishes, and is likewise antedated by Merycoideodon, which is now used by some writers. See Tylopoda.

ORESME, NICOLAS (c. 1320–1382), French bishop, celebrated for his numerous works in both French and Latin on scholastic, scientific and political questions, was born in Normandy at the opening of the 14th century. In 1348 he was a student in the college of Navarre at Paris, of which he became head in 1356. In 1361 he was named dean of the cathedral of Rouen. Charles V. had appointed bishop of Lisieux on the 16th of November 1377. He died in that city on the 12th of July 1382. One of his works, which is of great importance for the history of economics in the middle ages, was the De origine, natura, jure et mutationibus monetarum, of which there is also a French edition. Oresme was the author of several works on astrology, in which he showed its falseness as a science and denounced its practice. At the request of Charles V. he translated the Ethics, Politics and Economics of Aristotle. In December 1363 he preached before Urban V. a sermon on reform in the church, so severe in its arraignment that it was often brought forward in the 16th century by Protestant polemists.

ORESTES, in Greek legend, son of Agamemnon and Clytemnestra. According to the Homeric story he was absent from Mycenae when his father returned from the Trojan War and was murdered by Agamemnon. Eight years later he returned from Athens and avenged his father's death by slaying his mother, and her paramour (Odyssey, iii. 306; xi. 342). According to Pindar (Pythia, xi. 35) he was saved by his nurse, who conveyed him out of the country when Clytemnestra wished to kill him. The tale is told much more fully and with many variations in the tragedians. He was presented by his sister Electra from his father's fate, and conveyed to Phanope on Mount Parnassus, where King Strophius took charge of him.

In his twelfth year he was ordered by the Delphic oracle to return home and revenge his father's death. According to Aeschylus, he met his sister Electra before the tomb of Agamemnon, whether he had gone to perform rites to the dead; a recognition takes place, and they arrange how Orestes shall accomplish his revenge. Orestes, after the deed, goes mad, and is pursued by the Erinyes, whose duty it is to punish any violation of the ties of family piety. He takes refuge in the temple at Delphi; but, though Apollo had ordered him to do the deed, he is powerless to protect his suppliant from the consequences. At last Athens receives him on the acropolis of Athens and arranges a formal trial of the case before twelve Attic judges. The Erinyes demand their victim; he pleads the orders of Apollo; the votes of the judges are equally divided, and Athena gives her casting vote for acquittal. The Erinyes are propitiated by a new ritual, in which they are worshipped as Eumenides (the Kindly), and Orestes dedicates an altar to Athena Aréa. With Aeschylus the punishment ends here, but, according to Euripides, in order to escape the persecutions of the Erinyes, he was ordered by Apollo to go to Tauris, carry off the statue of Artemis which had fallen from heaven, and bring it to Athens. He repairs to Tauris with Pylades, the son of Strophius and the intimate friend of Orestes, and the pair are at once imprisoned by the people, among whom the custom is to sacrifice all strangers to Artemis. The priestess of Artemis, whose duty it is to perform the sacrifice, is his sister Iphigenia (q.v.). She here to release Orestes, but when a letter from her to Greece; he refuses to go, but bids Pylades take the letter while he himself will stay and be slain. After a conflict of mutual affection, Pylades at last yields, but the letter brings about a recognition between brother and sister, and all three escape together, carrying with them the image of Artemis. After his return to Greece, Orestes took possession of his father's kingdom of Mycenae, to which were added Argos and Laconia. He is said to have died of the bite of a snake in Arcadia. His body was conveyed to Sparta for burial (where he was the object of a cult), or, according to an Italian legend, to Arcia, whence it was removed to Rome (Servius on Aeneid, ii. 116). The story of Orestes was the subject of the Oresteia of Aeschylus (Agamemnon, Choephoroi, Eumenides), of the Electra of Sophocles, of the Electra, Iphigeniea in Tauris, and Orestes, of Euripides. There is extant a Latin epic poem, consisting of about 1000 hexameters, called Orestes Tragedia, which has been ascribed to Dracontius of Carthage.

Orestes appears also as a central figure in various legends connected with his madness and purification, both in Greece and Asia. In these Orestes is the guilt-laden mortal who is purified and absolved from the guilt of his crimes. He is a sinner who is purified and absolved. In the Homeric Orestes the soul of the murdered man has no claim to vengeance, and Orestes rules un molested in Argos. The Apolline religion introduces the theory of the rights of the soul and revenge for bloodshed. Apollo, who has urged Orestes to parricide and has himself expiated the crime of slaying the dragon, is able to purify others in similar case. Hence
ORFILA—ORFORD, 1ST EARL OF

Oresías, freed from the guilt of blood, is enabled to take possession of the throne of his father. This is the Delphic Orestes. But a new idea is introduced by the Attic Orestia. The claim that Apollo can in every case purify sin from sin is met by Athens with a counterclaim on behalf of the state. It is the community of which murder and murder are to be prevented. Ebb and flow, from retribution, an idea which found expression in the foundation of the Areopagus. If the accused is acquitted, the state undertakes to appease the soul of the murdered person or its judicial representative, the Myrmidons.

Others attach chief importance to the slaying of Neoptolemus (Pyrrhus) by Orestes at Delphi; according to Radermacher (Das Jenseits im Mythos der Hellenen, 1903), Orestes is an hypostasis of Apollo, the people of evil, which is overcome by the god on the other hand, Usener (Archiv für Religionswissen., vi., 1890, 334) takes Orestes for a god of winter and the underworld, a double of the Phocian Dionysus the "mountain" god (among the Ionians a summer-god). But in the case of Dionysus scholars who recognise Pyrrhus "the light," the double of Apollo, the whole being a form of the well-known myths of the expulsion of summer by winter. S. Reinach (reviewing P. Mazan's L'Orestie d'Eschyle, 1902) defends the theory of Bachelot, who finds in the legend of Orestes an indication of the decay of matriarchal ideas.

See article by Höfer in Roscher's Lexikon der Mythologie; A. Olivier, "Sul mito di Oresti nella letteratura classica" (with a section on modern literature) in Rivista di Filologia, xxvi. (1898), and Jebb's edition of the Electra of Sophocles.

ORFILA, MATHIEU JOSEPH BONAVENTURE (1787–1853). French toxicologist and chemist, was by birth a Spaniard, having been born at Mahon in Minorca on the 24th of April 1787. An island merchant's son, he looked naturally first to the sea for a profession; but a voyage at the age of fifteen to Sicily did not prove satisfactory. He next took to medicine, which he studied at the universities of Valencia and Barcelona with such success that the local authorities of the latter city made him a grant to enable him to follow his studies at Madrid and Paris, preparatory to appointing him professor. He had scarcely settled for that purpose in Paris when the outbreak of the Spanish war, in 1807, threatened destruction to his prospects. But he had the good fortune to find a patron in the chemist L. Vauquelin, who claimed him as his pupil, guaranteed his conduct, and saved him from expulsion from Paris.

Four years afterwards he graduated, and immediately became a private lecturer on chemistry in the French capital. In 1819 he was appointed professor of medical jurisprudence, and four years later he succeeded Vauquelin as professor of chemistry in the faculty of medicine at Paris. In 1830 he was nominated dean of that faculty, a high medical honour in France. Under the Orleans dynasty, honours were lavishly showered upon him; he became successively member of the council of education of France, member of the general council of the department of the Seine, and commander of the Legion of Honour. But by the republic of 1848 he was held in less favour, and chagrin at the treatment he experienced at the hands of the governments which succeeded that of Louis Philippe is supposed to have shortened his life. He died, after a short illness, in Paris on the 10th of March 1853.

Orfila's chief publications are Traité des poison, or Toxicologie générale (1813); Éléments de chimie médicale (1817); Leçons de médecine légale (1823); Traité des examinutions juridiques (1830); and Recherches sur l'empoisonnement par l'acide arsenique (1841). He also wrote many valuable papers, chiefly on subjects connected with and extending his native science. His other major contribution is his named work, published when he was only in his twenty-seventh year. It is a vast mine of experimental observation on the symptoms of poisoning of all kinds, on the appearances which poisons leave in the dead body, and on the physiological and pathological processes in the living body. He has shown that the small and delicate organs of the body are most susceptible to the poison; he has shown the whole of the symptoms which theيد and the nature of these symptoms. Few branches of science, so important on their bearings on everyday life and so difficult of investigation, can be said to have been created and raised at once to a state of high advancement by the labours of a single man.

ORFORD, EDWARD RUSSELL, EARL OF (1653–1727). British admiral, was born in 1653, the son of Edward Russell, a younger brother of the 1st duke of Bedford. He was one of the first gentleman officers of the navy regularly bred to the sea. In 1671 he was named lieutenant of the "Advice" at the age of eighteen, captain in the following year. He continued in active service against the Dutch in the North Sea in 1672–73, and in the Mediterranean in the operations against the Barbary Pirates with Sir John Narborough and Arthur Herbert, afterwards earl of Torrington, from 1676 to 1682. In 1683 he ceased to be employed, and the reason must no doubt be looked for in the fact that all members of the Russell family had fallen into disfavour with the king, after the discovery of William, Lord Russell's connivance with the R. Hovell Plot. The family had a private revenge to take which sharpened their sense of the danger run by British liberties from the tyranny of King James II. Throughout the negotiations preceding the revolution of 1688 Edward Russell appears acting on behalf and in the name of the head of this great Whig house, which did so much to bring it about, and profited by it so enormously in purse and power. He signed the invitation which William of Orange insisted on having in writing in order to commit the chiefs of the opposition to give him open help. Edward Russell's prominence at this crisis was of itself enough to account for his importance after the Revolution. When the war began with France in 1689, he served at first under the earl of Torrington. But during 1690, when that admiral avowed his intention of retiring to the Gunfleet, and of leaving the French in command of the Channel, Russell was one of those who condemned him most fiercely. In December 1690 he succeeded Torrington, and during 1691 he cruised without meeting the French under Tourville (q.v.), who made no attempt to meet him. At this time Russell, like some of the other extreme Whigs, was discontented with the moderation of William of Orange and accordingly entered into negotiations with the exiled court, partly out of self-interest and partly to make themselves safe in case of a restoration. But he was always ready to fight the French, and in 1692 he defeated Tourville in the battle called La Hogue, or Barfleur. Russell had Dutch allies with him, and they were greatly superior in number, but the chief difficulty encountered was in the pursuit, which Russell conducted with great resolution. His utter inability to work with the Tories, with whom William III. would not quarrel altogether, made his retirement imperative for a short time. But in 1694 he was appointed to the command of the fleet which, taking advantage of the inability of the king of France to maintain a great fleet in the Channel from want of money, followed the French into the Mediterranean, confined them to Toulon for the rest of the war, and co-operated with the Spanish armies in Catalonia. He returned in 1695, and in 1697 was created earl of Orford. For the rest of his life he filled posts of easy dignity and emolument, and died on the 26th of November 1727. He married his cousin, Mary Russell; but his title became extinct on his death without issue.

See Charnock, Biog. Nav. i. 334; Campbell's Lives of the Admirals, ii. 372. (D. H.)

ORFORD, ROBERT WALPOLE, 1ST EARL OF (1676–1745), generally known as SIR ROBERT WALPOLE, prime minister of England from 1721 to 1742, was the third but eldest surviving son of Robert Walpole, M.P., of Houghton in Norfolk, by Mary, only daughter and heiress of Sir Jeffery Burwell, of Rougham, in Suffolk. The father, a jolly old squire of Whig politics who revelled in outdoor sport and the pleasures of the table, transmitted to his son the chief traits in his own character. The future statesman was born at Houghton on the 26th of August 1676, was an Eton collegar from 1690 to 1695 and was admitted at King's College, Cambridge, as scholar on the 22nd of April 1696. At this time he was destined, as a younger son, for the church, but his two elder brothers died young and he became the heir to an estate producing about £2000 a year, whereupon on the 25th of May 1698 he resigned his scholarship, and was soon afterwards withdrawn by his father from the university. In classical attainments he was excelled by Pulteney, Carteret, and many others of his contemporaries in politics.

On his father's death in November 1700 the electors of the family borough of Castle Rising returned him (January 1701) to the House of Commons as their representative, but after two short-lived parliaments he sought the suffrages of the more important constituency of King's Lynn (July 23, 1702), and was elected as its member at every subsequent dissolution until he left the Lower House. From the first his shrewdness in counsel and his zeal for the interests of the Whigs were generally
recognized. In June 1705 he was appointed one of the council to Prince George of Denmark, the inactive husband of Queen Anne, and then lord high admiral of England. Complaints against the administration of the navy were then loud and frequent (Burton’s Queen Anne, ii. 22-31), and the responsibilities of his new position tested his capacity for public life. His abilities justified his advancement, in succession to his lifelong rival, Henry St John, to the more important position of secretary-at-war (February 25, 1708), which brought him into immediate contact with the duke of Marlborough and the queen. With this post he held for a short time (1710) the treasurership of the navy, and by the discharge of his official duties and by his skill in debate became admitted to the inmost councils of the ministry. He could not succeed, however, in diverting Godolphin from the great error of that statesman’s career, the impeachment of Sacheverell, and when the committee was appointed in December 1709 for elaborating the articles of impeachment Walpole was nominated one of the managers for the House of Commons. On the wreck of the Whig party which ensued, Walpole shared in the general misfortune, and in spite of the flattery, followed by the threats, of Harley he took his place with his friends in opposition. He was the most active and most influential member both of debate and in the pamphlet press he vindicated Godolphin from the charge that thirty-five millions of public money were not accounted for, and in revenge for his zeal his political opponents brought against him an accusation of personal corruption. On these charges, now universally acknowledged to have proceeded from party animosity, he was in January 1712 expelled from the House and committed to the Tower. His prison cell now became the rendezvous of the Whigs among the aristocracy, while the populace heard his praises commemorated in the ballads of the streets. The ignominy which the Tories had endeavoured to inflict upon him was turned into augmented reputation. In the last parliament of Queen Anne he took the leading part in defence of Sir Richard Steele against the attacks of the Tories.

After the accession of George, the Whigs for nearly half a century retained the control of English politics. Walpole obtained the lucrative if unimportant post of paymaster-general of the forces in the administration which was formed under the nominal rule of Lord Halifax, but of which Stanhope and Walpole were the real lords. For the next thirty years his energies were devoted to the Union of the Parliaments. Walpole was exalted into the conspicuous position of first lord of the treasury and chancellor of the exchequer (October 11, 1725). Jealousies, however, prevailed among the Whigs, and the German favourites of the new monarch quickly showed their discontent with the heads of the ministry. Townsend was forced into resigning his secretaryship of state for the dignified exile of vicecy of Ireland, but he never crossed the sea to Dublin, and the support which Sunderland and Stanhope, the new advisers of the king, received from him and from Walpole was so grudging that Townsend was dismissed from the lord-lieutenancy (April 9, 1725), and Walpole on the next morning withdrew from the ministry. They plunged into opposition with unflagging energy, and in resisting the measure by which it was proposed to limit the royal prerogative in the creation of peers (March-December 1728) Walpole exerted all his powers. This display of ability brought about a partial reconciliation of the two sections of the Whigs. To Townsend was given the presidency of the council, and Walpole once again assumed the paymastership of the forces (June 1729).

On the financial crash which followed the failure of the South Sea scheme, the public voice insisted that he should assume a more prominent place in public life. At this crisis in England’s fortunes Stanhope and James Craggs, the two secretaries of state, were seized by death, John Aislabie, the chancellor of the exchequer, was committed to the Tower, and Sunderland, though acquitted of corruption, was compelled to resign the lead. Walpole, at first lord of the treasury and chancellor of the exchequer (April 1727), became with Townshend responsible for the country’s government (though for some years they had to contend with the influence of Carteret), the danger arising from the panic in South Sea stock was averted by its amalgamation with Bank and East India stock, and during the rest of the reign of George I. they remained at the head of the ministry. The hopes of the Jacobites, which revived with these financial troubles, soon dropped in disappointment. Atterbury, their boldest leader, was exiled in 1723; Bolingbroke, in dismay at their feebleness, sued for pardon, and was permitted to return to his own country. The troubles which broke out in Ireland over Wood’s patent for a copper coinage were averted through the tact of Carteret, who had been banished in April 1724 as its lord-lieutenant by his triumphant rivals. The continent was still troubled with wars and rumours of wars, but a treaty between England, Prussia and France was successfully effected at Hanover in 1725.

England was kept from war by, and in the general proceedings of the House of Commons Walpole basked in the royal favour. His eldest son was raised to the peerage as Baron Walpole (June 10, 1723) and he himself became a Knight of the Bath on the 27th of May 1725, and was rewarded with the Garter in May 1726. Next year the first King George died, and Walpole’s enemies fondly believed that he would be driven from office, but their expectations were doomed to disappointment. The confidence which the old king had reposed in him was renewed by his successor, and in the person of Queen Caroline, the discreet ruler of her royal spouse, the second George, the Whig minister found a faithful and lifelong friend. For three years he shared power with Townshend, but the jealous Walpole brooked no rival near the throne, and his brother-in-law withdrew from official life to Norfolk in May 1730. Before and after that event the administration was based on two principles, sound finance at home and freedom from the intrigues and wars which reigned abroad. On the continent congresses and treaties were matters of annual arrangement, and if the work of the plenipotentiaries soon faded it was through their labours that England enjoyed her prosperity. Both French and Austrian envoys were compelled to bow in 1733. The enormous frauds on the excise duties forced themselves on his attention, and he proposed to check smuggling and avoid fraud by levying the full tax on tobacco and wine when they were removed from the warehouses for sale. His opponents fastened on these proposals with irresistible force, and so serious an agitation stirred the country that the ministerial measure was dropped amid general rejoicing. Several of his most active antagonists were dismissed from office or deprived of their regiments, but their spirits remained unquenched, as the incessant attacks in the Craftsman showed, and when Walpole met a new House of Commons in 1734 his supporters were far less numerous. The Gin Act of 1736, by which the tax on that drink was raised to an excessive amount, led to disorders in the suburbs of London; and the imprisonment of two notorious smugglers in the Tolbooth at Edinburgh resulted in those Porteous riots which have been rendered famous in the Heart of Midlothian. These events weakened his influence with large classes in England and Scotland, but his parliamentary supremacy remained unimpaired, and was illustrated in 1737 by his defeat of Sir John Barnard’s plan for the reduction of the interest on the national debt, and by his passing of the Playhouse Act, under which the London theatres are still regulated. That year, however, heralded his fall from power. His constant friend Queen Caroline died on the 20th of November 1737, and the prince of Wales, long discontented with his parents and their minister, flung himself into active opposition. Many of the boroughs within the limits of the duchy of Cornwall were obedient to the prince’s will, and he quickly attracted to his cause a considerable number of adherents, of whom Pitt and the Grenvilles were the most influential. The leading orators of England thundered against Walpole in the senate,
and the press resounded with the taunts of the poet and pamphleteer, illustrious and obscure, who found abundant food for their invectives in the troubles with Spain over its exclusive pretensions to the continent of America and its claim to the right of searching English vessels. The minister long resisted the pressure of the opposition for war, but at the close of 1739 he abandoned his efforts to stem the current, and with a divided cabinet was forced, as the king would not allow him to resign, into hostility with Spain. The Tory minority known as "the patriots" had seceded from parliament in March 1739, but at the commencement of the new session, in November 1739, they returned to their places with redoubled energies. The campaign was prosecuted with vigour, but the successes of the troops brought little strength to Walpole's declining popularity, and when parliament was dissolved in April 1741 his influence with his fellow-countrymen had faded away. His enemies were active in opposition, while some of his colleagues were lukewarm in support. In the famous House of Commons political parties were almost evenly balanced. Their strength was tried immediately on the opening of parliament. After the ministry had sustained some defeats on election petitions, the voting on the return for Chippenham was accepted as a decisive test of parties, and Walpole was beaten in the divisions, he resolved on resigning his places. On the 6th of February 1742 he was created earl of Orford, and two days later he ceased to be prime minister. A committee of inquiry into the conduct of his ministry for the previous ten years was ultimately granted, but its deliberations ended in nothing. Although he withdrew to Houghton for a time, his influence over public affairs was unbroken and he was still consulted by the monarch. He died at Arlington Street, London, on the 18th of March 1745 and was buried at Houghton on the 25th of March. With the permanent places, valued at £15,000 per annum, which he had secured for his family, and with his accumulations in office, he had rebuilt the mansion at greatest expense, the walls of pictures which in its walls at a cost of £40,000, but the collection was sold by his grandson for a much larger sum in 1779 to the empress of Russia, and the estate and house of Houghton passed to Lord Cholmondeley, the third earl having married the premier's younger daughter.

Walpole was twice married—in 1700 to Catherine, eldest daughter of John Shorter and grand-daughter of Sir John Shorter, lord mayor of London, who died in 1737, having had issue three sons and two daughters, and in March 1738 to Maria, daughter of Thomas Skerret, a lady often mentioned in the letters of Lady Mary Wortley Montagu. He was succeeded in his earldom and other titles by his eldest son Robert (1701–1751), who had been created Baron Walpole of Walpole in 1723; the 3rd earl was the latter's only son George (1730–1797), "the last of the English nobility who practised the ancient sport of hawking," and the 4th earl was his cousin, Horace Walpole (1717–1797), the youngest son of the great Sir Robert. Horace Walpole died unmarried on the 2nd of March 1797, when the earldom became extinct, but the barony of Walpole of Walpole passed to his cousin, Horatio (1723–1809), who had already succeeded his father, Horatio Walpole, 1st Baron Walpole of Woltewton in that barony. In 1806 he was created earl of Orford, and this title still remains in the possession of his descendants, Robert Horace Walpole (b. 1854) becoming the 5th earl in 1894. When Horace Walpole died his splendid residence at Houghton and the Norfolk estates did not pass with the title, but were inherited by George James Cholmondeley, 4th earl and afterwards 1st marquess of Cholmondeley.

Sir R. Walpole's life has been written by Archdeacon William Cavendish (1818) in two volumes. A Life (1878) and John Viscount Morley (1889). See also Walpole, a Study in Politics, by Edward Jenks (1894): English Hist. Rev. xv. 251, 470, 665, xvi. 67, 308, 439 (his foreign policy, by Basil Williams); Baldingbrooke, by Walter Carter (1902, 2 vols.); the histories, letters and reminiscences by his son, Horace Walpole; and the other lives of the chief political personages of the period. (W. P. C.)

ORFORD, a small town, once of greater importance, in the south-eastern parliamentary division of Suffolk, England, 31 m. E. by N. of Ipswich. Pop. (1901) 897. It lies by the right bank of the river Alde, where that river flows south-westward on the inner side of the great beach which has blocked its direct outflow to the sea, and swells out seaward in the blunt promontory of Orford Ness. The church of St Bartholomew is of much interest. It retains a ruined Norman chancel of rich and unusual design, while the body of the church is Decorated. Of Orford castle the keep remains, standing high on a mound; it is partly of Caen stone and partly of flintwork, and is of Norman date.

ORGAN, in music, the name (from Gr. orgaw, Lat. orgam, instrument) given to the well-known wind-instrument. The notes of the organ are produced by pipes, which are blown by air under pressure, technically called wind.

Pipes differ from one another in two principal ways—(1) in pitch, (2) in quality of tone. (1) Consider first a series of pipes producing notes of similar quality, but differing in pitch. Such a series is called a stop. Each stop of the organ is in effect a musical instrument in itself. (2) The pipes of different stops differ, musically speaking, in their quality of tone, as well as sometimes in their pitch. Physically, they differ in shape and general arrangement. The sounding of the pipes is determined by the use of keys, some of which are played by the hands, some by the feet. A complete stop possesses a pipe for every key of some one row of manuals or pedals. If one stop alone is caused to sound, the effect is that of performance on a single instrument. There are such things as incomplete stops, which do not extend over a whole row of keys; and also there are stops which have more than one pipe to each key. Every stop is provided with mechanism by means of which the wind can be cut off from its pipes, so that they cannot sound even when the keys are pressed. This mechanism is made to terminate in a handle, which is commonly spoken of as the stop. When the handle is pushed in, the stop does not sound; when the handle is pulled out, the stop sounds if the keys are pressed. An organ may contain from one to four manuals or keyboards and one set of pedals. There are exceptional instruments having five manuals, and also some having two sets of pedals. The usual compass of the manuals approximates to five octaves, from C to e'' inclusive. The compass of the pedal is two and a half octaves, from C to f'. This represents the pitch in which the notes of the pedal are written; but the pedal generally possesses stops sounding one octave lower than the written note, and in some cases stops sounding two octaves below the written note. Each manual or pedal has as a rule one soundboard, on which all its pipes are placed. Underneath the soundboard is the windchest, by which the wind is conveyed from the bellows, through the soundboard to the pipes. The windchest contains the mechanism of valves by which the keys control the admission of wind to the soundboard. The soundboard contains the grooves which receive the wind from the valves, and the slides by which the stops control the transmission of the wind through the soundboard to the pipes of the different stops.

The grooves of the soundboard are spaces left between wooden bars glued on to the table of the soundboard. There is usually one groove for every key. The grooves of the bass notes, which have to supply wind for large pipes, are always in number greater than those of the treble. The bass pipes are also thicker than those of the treble, that they may the better support the great weight which rests on the bass portion of the soundboard. The table forms the top of the grooves. The grooves are generally closed below with
leather, except the opening left in each, which is closed by the key-valve or pallet.

The sliders are connected with the draw-stops or stop-handles, which are covered in with stout upper boards, on which the pipes stand. The stop-handles are pulled out, and holes are then bored straight down through the upper boards, sliders and table to admit the wind from the grooves to the pipes. When the sliders are shifted by pushing in the handles, the holes no longer correspond, and the pipes are silenced.

Pipes are divided first into flue-pipes and reed-pipes. Flue-pipes are blown by a wind mouthpiece characteristic of the organ, while in reed-pipes the wind acts on a metal tongue vibrating on a reed, and the motion of the tongue determines the speech of the pipe.

Pipes are made either of wood or of metal. Wood flue-pipes are generally of the form of a rectangular parallel-epiped, metal flue-pipes of a cylindrical shape. Reed-pipes are conical or pyramidal, and widen towards the top. Some flue-pipes are made with stopped ends; these as a rule sound a note about an octave lower than the corresponding open pipes of the same length. Such are the stopped diapason, bourdon, and stopped flue.

The general elementary theory of the resonance of a pipe is tolerably simple. The effective length of the pipe is determined by measuring from the upper lip to the open end in open pipes, and from the upper lip to the stopper and back again in stopped pipes. To this is added an allowance for the effect of each opening, since the condition of perfect freedom from constraint does not subsist at the opening itself. The corrected length is traversed twice (backwards and forwards) by sound, in the time of one vibration of the resultant note. This describes in a rough and general manner the way in which any disturbance gives rise to the note of the pipe; but the theory of the mouth-pieces is a much more difficult matter, into which we cannot here enter.

But the resonance of the body of the pipe is generally the same as the note produced. The tongue of a reed-pipe alternately opens and closes the aperture of the reed. In this way it admits pulses of wind to the body of the pipe; these, if they recur at the proper intervals, maintain its vibration, which takes place when the note produced corresponds to the resonance of the pipe. The reed itself has its vibrating length determined by a wire which presses against it. The free end of this wire is touched with the tuning tool until a satisfactory note is produced.

The pitch of the different stops is commonly denoted by the conventional approximate length of the pipe sounded by C, the lowest key of the manual. Even in incomplete stops which have no base, the length of the pipe which C would have if the stop were extended down serves to indicate the pitch.

The conventional length of the C-pipe for stops having the normal pitch of the keys is 8 ft.; a pipe having twice this length sounds the octave below, a pipe having half that length the octave above, and so on. Thus stops which sound the octave below the normal pitch of the keys are spoken of as 16-foot stops. Even where the pipes are stopped so that the actual length is only 8 ft., they are spoken of as having "16-ft. tone." Similarly 32-ft. stops sound two octaves below the normal pitch of the keys. But if these notes are produced by stopped pipes, whose actual length is only 16 ft., they are spoken of as having "32-ft. tone." Sixteen-foot and 32-ft. stops are specified characteristic of the pedal, where the names also signify the length of the open pipe which would sound the note actually produced by the lowest C. Of stops higher than the normal pitch of the keys, the octave is denoted by 4 ft. if made with open pipes, 4-ft. tone if stopped; the twelfth is commonly spoken of as \( \frac{3}{2} \), the fifteenth or double octave as 2 ft. Higher-sounding stops are occasionally used, but these generally form part of "mixtures," and the foot-lengths of the separate ranks are not usually given.

The true or accurate lengths of the pipes vary within considerable limits. The base of the scales (dimensions) varies according to the standard of pitch, and the voicing and the complicated natural laws of pipes produce other deviations from simple relations, so that the conventional dimensions can only be regarded as a simple means of classifying the stops according to their pitch-relations. For this purpose they are essential; they are continually appealed to in discussion and description; and they are almost invariably marked on the stop-handles in all countries, so that a moderate knowledge of foreign nomenclatures, combined with the habit of seizing the meaning of the figures such as 16, 8, 4, on the stop-handles, will frequently suffice as a key to the complexities of a foreign organ.

Each of the manuals, or rows of keys, of an organ constitutes a separate organ, which is more or less complete in itself. The names of the different manuals or organs are great organ, swell organ, choir organ and solo organ. The fifth manual, where it occurs, is the echo organ. The above is the usual order in point of development and frequency of occurrence, although the solo is sometimes preferred to the choir organ. The great organ is in a certain sense the principal department of the organ. It may be regarded as formed by a completely developed series of those fundamental stops which constitute the solid basis of the tone of the instrument. If an instrument be constructed with only a single manual this necessarily assumes, in general, the characteristics of a great organ. The great organ is called "grande orgue" in French, and first manual or "haupt-werk" in German.

It is proposed to describe the principal organ-stops under the
Heads of the manuals to which they belong. The enumeration will not be exhaustive, but will include all the usual types.

The great organ begins generally with stops of 16 ft. in large instruments. The 8-ft. sounding stop is introduced, but this cannot be said to be a proper characteristic of the great organ. The foundation tone is a 8-ft.; the stops of higher pitch serve to add brilliancy; those of 16 ft., however, being more common in the lower range of the organ, are an important part of the combination. The treble stops are commonly of short length. Sixteen-foot stops are commonly spoken of as "double," their conventional length being twice that of stops of normal pitch.

The 8-ft. stops are the 16 double diapason, and the 16 bourdon or double stopped diapason, to which, in very large instruments, there may be added a 16 double trumpet. The double diapason on the great organ consists usually of metal pipes, having moderate pitch and being moderately thick in section. These are generally classified as having a general character as the pipes of the ordinary open diapason, though they are made somewhat less powerful. In the better instruments of the second class as to size this stop alone would probably be regarded as a representative of the great organ. It gives great body to the general tone, and appears decidedly preferable to the bourdon, which frequently takes its place. The 16 bourdon, when used on the great organ, is made of rather small scale and light tone. It gives great warmth and richness to the diapason, and to other stops such as the 4-ft. flute. It is used either alone in smaller organs of the second class, or in addition to a double open in larger instruments.

The 16 double trumpet is a trumpet (large reed stop) including the octaves of the 8-ft. diapason, and is generally used as an additional stopping in instruments of the largest size, but is somewhat more common in Germany. It is useful in giving a massive character to the tone of the great organ, which is apt to become disagreeable on account of the great dimensions of the organ. It is not found in any great degree alone, but whenever the diapason is of pronounced character, it is used either alone or is added to the diapason when the double diapason is rough in tone, it is apt to communicate to the whole a corresponding impression.

We now proceed to the 4-ft. stops (the reeds come at the end according to ordinary usage). An ordinary great organ may contain 8 stopped diapason, 8 open diapason (one or more), 8 gamba and 8 hohlflöte. The 8 stopped diapason on the great organ is usually of moderate scale, and some combinations of the organ have 8 open stops of a similar character. If there is any one stop which in itself represents the organ as a whole it is the open diapason. The pipes of this stop are the actual metal pipes which have always been characteristic of the organ. It is a single open diapason stop capable of being used as an organ of sufficient power for many purposes, though of course without variety. The pipes of this stop are called "principal" in German, this appellation apparently corresponding to the fact that the original type of organ with a single manual and the organ of "diapason" has been taken to mean that these are the normal pipes which run through the whole compass. This, however, does not appear to be the actual derivation of the term; originally it is thought that the term was applied to a certain portion of the organ and its dimensions, giving the indication of the pitch; and pipes and it appears that the application to the stop followed on this meaning.

The scales, character and voicing of the open diapason vary with fashion, as is said for four. The development of the principal stops of three principal types. The old English diapasons of the days before the introduction of pedal organs into England were characterized by a rich sweet tone, and were not powerful. They were generally voiced on a light wind, having a pressure equivalent to that of a column of water of from 2 to 2 1/2 in. The scale was in some cases very large, as in Green's two open diapasons in the organ at St. George's, Windsor; in these the wind was light, and the tone very sweet, but with the very full sound which was obtained in St. Paul's Cathedral. But on the whole the old English diapasons presented a lovely quality of tone. English travellers of those days, accustomed to these diapasons, usually found foreign organs harsh, noisy and unsuited to their atmosphere. The English organ has always been the starting point for the foundation of other organs, and when speaking of the great organ, it is not necessary to present the characteristics of the English organ, combined with sufficient fulness and power to form a sound general foundation. And there can be no doubt that this stop should be one of the most important in any proper organ. The German diapason was of an entirely different character from the English. The heavy bass of the pedals has been an essential characteristic of the German organ for at least two or three centuries, and it is said for four. The development of the principal stops of high pitch was equally general. Thus foundation work of comparatively great power was required to maintain the balance of tone; the ordinary German diapason was very loud, and we may almost say coarse, in its tone when compared with the old English diapason.

The German stop was voiced as a rule on from 33 to 4 in. of wind, not quite twice the pressure used in England.

The French diapason is a modern variety. It may be described as a somewhat barred or rather coarse, of a slightly inharmonic quality. In other words the tone tends towards a certain quality which may be described as "nasal" or metallic, or as approaching to that of a string instrument of rather coarse character. Some modern French organists and organ builders appear to aim at the same model, and not without success.

The tone of a diapason must be strong enough to assert itself. It is the foundation of the whole organ tone. It is the voice of the business to be done. This consideration is perhaps the reason that the tone shall be full and of agreeable quality.

The 8 spitzflöte may be regarded as a variety of open diapason. The pipes taper slightly towards the top, and the quality is thus more percussive. This quality is desirable in the case of the second open diapason. But it appears better that, when these diapasons are desirable, they should both be of full diapason quality, though possibly of different strengths and dimensions. The addition of other qualities of tone with the diapasons is always to be deprecated.

The 8 gamba was originally an imitation of the viola da gamba, a sort of violoncello. When made of a light quality of tone it is a stop; but its use in the great organ instead of a second open diapason, is due to the reasons just stated in the case of the 8 spitzflöte.

The 8 hohlflöte is an open flute, usually of wood, and of small scale. If made to a moderate scale and fully voiced it possesses a bright, clear tone, which is a useful support to the foundation tone of the great organ. It is a stop of the organ which is usually of rather large scale, and having the open pipes only in the treble. In old organs a separate bass was generally provided; now it is more usual to supply the stop with a stop bass below.

The 4-ft. stops of the great organ comprise the 4 principal and the 4 flûte. The 4 principal is the octave of the open diapason, generally of somewhat reduced scale and light but bright quality of tone. The use of the word "principal" in connexion with this stop is purely English, and is said to be connected with the use made of it as the standard of tuning for the whole organ. The Germans and French both designate this stop as "4 octave." Of the 4 flûte there are several varieties—open, stopped, wood, metal and harmonic. The harmonic flûte has open metal pipes of double the conventional length, which speak their octave. This is done partly to increase the length of the stop, partly to make it capable of being used in being usually of rather large scale, and having the open pipes only in the treble. Harmonic flûtes have a sweet but full and powerful tone. Other flutes are generally rather light, except the Waldflöte, which is a powerful stop of a somewhat hooting quality.

The great organ flutes are frequently used to give brilliancy to light combinations. Thus it may be used with the stopped diapason alone, or with any of these and either or both of the open diapasons.

The ordinary use of the 4-ft. stops is to add a degree of loudness to the diapasons. This is accompanied with a certain measure of keenness, or the organ may become disagreeable if the 4-ft. tone is disproportionately strong. The ordinary practice is to use the 4-ft. tone very freely.

The 2 1/2 thwelfth stop sounds fiddle g in the C key. It is composed of metal pipes of small and uniform notes. Its use is said to be to thicken the tone, which it certainly does. But how far the particular effect produced is desirable is another question. It is generally necessary that this stop should be accompanied by the fifteenth or other octave sounding stop of higher pitch.

The 2 15th, or superoctave, of the great organ consists of diapason pipes sounding notes two octaves above the normal pitch of diapason. It is a powerful stop of less power, having the same pitch. The 2-ft. tone is commonly used in giving depth of loudness to the organ beyond that obtainable with the 4-ft. tone.

The modern great organ fifteenth is generally a very powerful stop, and requires great caution in its use in organs of moderate size, or in limited spaces. The old English high pitched stops had little power, and their brilliancy was capable of pleasing without offence. The modern great organ up to fifteenth can only be heard with comfort in very limited spaces. The fifteenth is capable of giving to the whole tone a ringing or silvery character, which lends itself specially to contrast with the tone of reeds. This peculiar tone requires for its full development the use of a Mixture, sesquialtera, furniture, cymbal, scharf, cornet, are various names applied to a description of stop which possesses several ranks or several pipes to each note. The pipes of each note sound a chord which is generally composed of concordant notes of the harmonic series and which have fundamental proper note of the key. Modern mixtures generally consist of fifths and octaves. Their combination is not the same throughout the whole range of the keyboard.
three-rank mixture may consist of the following (the numbers signify
intervals, reckoned along the scale)—

\[
\begin{align*}
C & \rightarrow (tenor) 15 \rightarrow 19 \rightarrow 22 \\
C & \rightarrow (middle) 15 \rightarrow 19 \rightarrow 22 \\
C & \rightarrow (bass) 15 \rightarrow 19 \rightarrow 22 \\
\end{align*}
\]

For a somewhat larger full mixture this may be modified as follows—

\[
\begin{align*}
C & \rightarrow (tenor) 15 \rightarrow 19 \rightarrow 22 \\
C & \rightarrow (middle) 15 \rightarrow 19 \rightarrow 22 \\
C & \rightarrow (bass) 15 \rightarrow 19 \rightarrow 22 \\
\end{align*}
\]

A sharp mixture suitable for a large instrument may be as follows—

\[
\begin{align*}
C & \rightarrow (tenor) 7 \rightarrow 11 \rightarrow 14 \\
C & \rightarrow (middle) 7 \rightarrow 11 \rightarrow 14 \\
C & \rightarrow (bass) 7 \rightarrow 11 \rightarrow 14 \\
\end{align*}
\]

The last two compositions are given by Hopkins in his great treatise on the organ.

The early mixtures generally included the tierce, (17th, or two
octaves and a third). The German practice was to unite this with
a tweith, carrying the combination 12-17 throughout the
keyboard under the name of sesquialtera. The combination is not now usually
provided. The old English sesquialter was ordinarily simply a form of
mixture, as was the furniture. The mounted cornet consisted
usually of five ranks—

\[
\begin{align*}
C & \rightarrow (1) 8 \rightarrow 12 \rightarrow 15 \rightarrow 17 \\
C & \rightarrow (2) 8 \rightarrow 12 \rightarrow 15 \rightarrow 17 \\
C & \rightarrow (3) 8 \rightarrow 12 \rightarrow 15 \rightarrow 17 \\
C & \rightarrow (4) 8 \rightarrow 12 \rightarrow 15 \rightarrow 17 \\
C & \rightarrow (5) 8 \rightarrow 12 \rightarrow 15 \rightarrow 17 \\
\end{align*}
\]

It extended from middle C upwards. The pipes were raised on a small
soundboard of their own. The stop was used for giving out a melody. It is now obsolete.

The question of the employment and composition of mixtures is
probably the greatest importance with respect to the good effect of the full
organ proper, i.e., that mixture made directly available to the whole. The question of keen-toned stops may be laid down that their free
employment in the great organ does not produce a good effect unless the
organ is situated in a very large space. If this is the case, properly
proportioned mixtures are capable of giving to the tone of the full
diapason work a character which is brilliant without being over-powering.

The contrast between this class of tone and that afforded by the reeds is one of the most charming and legitimate effects within
the organ compass.

We now pass to the reeds. The 16-ft. trumpet has already
alluded to, and there remain 8 trumpet and 4 clarion or octave
trumpets. These are both stops of great power. The best trumpets, however, are also rich in the smoothness of their
tone. Stops of this class can be used with the diapasons only
producing what may be described as a rich-toned blare of
mixture. The more usual employment of the reeds is in conjunction with the great organ, the whole forming the ordinary
fortissimo of the instrument.

The second department of the English organ is the swell organ.
The whole of the swell pipes are enclosed in a box, faced on one or
more sides with a set of sliding shutters. When the shutters are
closed the tone is almost completely muffled. When
the shutters are opened, by means of a pedal usually, the sound bursts out. In order that the use of the swell may be effective, it
is necessary that there be no mixtures in the box, as they
should be placed with the shutters closed; it is only then that the
organ is truly swell. The swell is of entirely French origin; it has been
introduced into Germany to a very small extent, yet more widely in
France. It is used in England almost exclusively.

The chief characteristic of the swell is the rich and powerful volume
of reed-tone of a peculiar character which it contains. But other stops
are also of importance. We consider them in order. The 16 bourdon,
small scale, is very commonly used in swells. It assists in giving
to the swell a rich and, as it is often called, "English" character.

The 8-ft. diapason work is principally valuable for the soft effects
obtained from the swell itself. This organ may be contrasted to
that of the English organ. The shutters tone them down, so that they
cannot easily become offensive. Added to the reeds, they give a peculiar brilliancy to the full swell. But perhaps their most pleasing
use is when the diapason work of the swell is used alone, and as a

The usual reeds are as follows, besides the doubles already mentioned: 8 oboe, 8 cornopean, 8 trumpet and 4 clarion (octave
trumpet). The oboe (hautboy) is a conventional imitation of the
or the organ. It is a stop of delicate tone, and perhaps a
bit of a solo stop, or at least one which can be employed in
combination with other stops, to add to the richness of
the tone. The cornopean has a powerful horn-like tone. It is the stop which
more than any other, gives to the English swell its peculiar
character. The trumpet is used in addition to the cornopean in large
instruments. The cornopean is placed in the box, and the rest of the
organ is placed on the swell. The vox humana is also frequently placed on the swell.

The third department is the choir organ. The 8-ft.
work may contain 8 stopped diapason, 8 open diapason,
8 trombone, 8 keraulion and 8 bollicine.

As a rule no open diapason is provided for choir organs, unless they are
larger than usual; but a small open is most useful as a means of
obtaining a better balance than usual against the other
months. The 8-ft. and 8-octave diapason in the French
organ is nearly the same stop as on the great organ, but
it is generally lighter than what would be put on the great organ. The
keraulion is placed in the box, and the rest of the
organ is placed on the swell. As the gambe is better placed in the choir organ than in the great or the
swell, any such stops as the gambe and the keraulion are frequently placed on the swell with the idea of adding to the richess of the

The last three stops are the swell stops. These may be
advantageously used for certain passages. The last three stops
are couplers. They are used to advantage in enclosed
swell box, having a separate pedal. In very large instruments a
number of additional couplers of both diapason and swell stops is occasionally placed
on the swell. But there does not seem to be much advantage
in this arrangement.

So far as the pedal organ is concerned, as usual, the
organ proper appears to have arisen with Cavaille-Coll in France, and Hill
in England, as a vehicle for the powerful swell-stops on heavy
wind introduced by these builders. Thus the French term for the solo
is "pédale," and the English term is "bass," both being

A tuba mirabilis was usually prominent. A solo organ may suitably
contain any of the following stops: 8 tromba (a powerful reed on
heavy wind), 8 harmonie flute (powerful tone and heavy wind), 8
diapason (solo open diapason), 8 cornopean (a trombone
of larger scale, and produces true musical notes throughout
musical effect in the lower part of its range is, however, questionable, so far as
this depends on the possibility of recognizing the pitch of the notes. It adds
great richness to the general effect, particularly in
large spaces. The 32-ft. tone bourdon is not usually a successful stop.
ORGAN

It rarely produces its true note in the lower part of its range. The 32-ft. reed on the pedal has long been a characteristic of the larger organs. With the old type of reed it was rarely pleasant to hear. The manufacture has been greatly improved, and these large reeds are now made to produce a fairly smooth effect. Deep reeds, when rich and good, undoubtedly form one of the principal elements in giving the impression of power produced by large organs. From this point of view they are of great importance. Nevertheless the bass needs are generally more satisfactory to the performer than to the listener.

The 16-ft. pitch may be regarded as the normal pitch of the pedal; the principal stops are as follows: 16 open diapason (wood or metal), 16-ft. tone bourdon, 16 violone (imitation of double bass) and 16 trombone. This form of the pedal indicates the general characteristic of the pedal department of the organ, and the 16-ft. stop is therefore not a very satisfactory one for the accompaniment of the full organ, or of very powerful manual combinations. Such a stop is, as a rule, unsuitable in organs of moderate size, unless supplemented by lighter 16s for ordinary purposes. The metal open is of considerably smaller scale (in fact, all metal pipes are effectively of much smaller scale than wooden pipes of similar diameter). The metal gives a clear tone, lighter than that of large wooden pipes, and pleasanter for ordinary purposes. The metal open is, however, only suitable for the largest organs both wood and metal open 16s may be suitably provided. Where metal pipes are made a feature in the organ-case, both the double open diapason in the great organ and the metal 16 of the pedal should be made of the same metal (polished tin or silver plate), and worked in to the design of the organ-case.

The same applies to the 32-ft. metal opens of the largest instruments. This saves space in the interior, and gives the large pipes room to speak, which is apt to be wanting when they are placed inside. The 32-ft. is apt to give the impression of any scale according to circumstances. If it is the chief bass of the organ it is made very large and with great volume of tone. Such stops are unsuitable for soft purposes, and a soft 16, usually a violone, is required in cases where the 16-ft. stop is the only one provided for the bourdon may be of moderate strength. It may also be made very soft, like a manual bourdon. These three different strengths ought always to be provided for in an instrument of this size, and to be used in any combination of their forces. In a few cases it furnishes the principal bourdon; frequently it furnishes the moderate element; and it is often applied to obtain a very soft 16-ft. tone. The 16-ft. reed is very common. The objections made to the effect of 32-ft. reeds are applicable also in this case.

The 8-ft. department of the pedal is only less important than the 16, because it is possible to replace it to a certain extent by coupling or attaching to the manuals to the usual 8-ft. pedal. The various stops for the 8-ft. are: 8 principal (metal or wood), 8 bass flute (stopped), 8 violoncello (imitation of the instrument) and 8 trumpet. These remarks made above as to the scale of open 16s apply with little change to the pedal principal. Only, since the manuals are generally coupled, the 8 doux register is provided, and this represents the powerful class of tone in which the manuals diapasons are deficient. The bass flute is almost a necessity in combination with the light 16-ft. tone. A coupling ought to be provided by which the tone can be used to these two elements by a single movement. The violoncello is sometimes used instead of the bass flute for the last-named purpose, for which, however, it is not so suitable. It is a favourite stop for some solo purposes, but is not of much general utility. The 8-ft. trumpet serves to give clearness and point to the tone of the 16-ft. reed.

In the short preface to Mendelssohn's Organ Sonatas it is stated that everywhere, even in pianissimo, it is intended that the 16-ft. tone of the pedal should be accompanied by another 8-ft. tone as a general direction the soft 16-ft. and 8-ft. stops are required; large instruments are, however, occasionally found which possess nothing of the kind.

The following stops of higher pitch are occasionally found on the pedal, 4 open diapasons, a mixture and 4 clarions. These serve to make the pedal tone practically independent of coupling to the manual, which is a matter of great importance, especially in the performance of certain compositions of Bach and other composers who have an independent organist.

In some instruments two sets of peddles are provided, which may be described as great, and choir peddles. In the great peddles the choir pedal is in the usual position; the choir pedal is in front of the other, and is also the pedal of the instruments naturally when stretched out in front of the performer. There is a choir pedal of this kind in the organ in the minster at Ulm, built by Walcker of Ludwigsburg. It is a very large instrument, having 100"

1 Anything down to one-third and two-thirds lead is called tin. But "pure tin" should have over 90% of tin. Absolutely pure tin could not be worked. Spotted metal is said to have from one-third to two-thirds tin. Under one-third tin no spots are said to rise, and the mixture has the general characters of lead.
the great organ, as is very commonly the case, the octaves are reached through two couplers. And, as couplers are not generally screwed up quite tight, the octaves are often not sufficiently put down to sound in tune. The choir to great sub-octave coupler was used chiefly as a substitute for a double on the great organ. It is common in organs of the transition period, but is largely replaced by the pedal arrangement.

The pneumatic lever (fig. 13) consists of a small power bellows attached to each key, so that the depression of the key admits high-pressure wind to the power bellows. The power bellows then performs the function of the key.

Pneumatic transmission, with many other mechanical devices, was invented by Willis. It consists of a divided pneumatic action. The pneumatic wind, instead of being admitted to the power bellows, is made to traverse a length of tubing, at the farther end of which it reaches the work to be done. This principle admits of application to divided organs, the pneumatic transmission passing under the floor, as in the organ at St Paul's Cathedral.

Vents are valves which control the wind-supply of the different groups of stops. They were much recommended at one time as a substitute for compositions. The practical difference is that compositions shift the stop-handles, whereas so that one can always see what there is on the organ; vents leave the stop handles unmoved, so that the player will be able to be deceived. Other inferences might be mentioned, but it is enough to say that practical opinion appears decidedly to condemn the use of vents.

The original pedal boards of German were flat and of very large scale. The early practice in England was to make them very small, as well as of short compass. Of late the compass C−f', thirty notes, has been universally adopted with scales varying from 2½ to 3½ in. from centre to centre. The natural C−f' in the scale now recommended. A large number of organs have been provided with concave radiating pedal boards. The objections to this arrangement are mainly two: They present different scales at different distances from the front; and, except just in front, they become so narrow that the smallest foot can hardly put down the pedals singly, withers so that renders difficult the old Bach style of playing, the essence of which consists in putting the feet over each other freely, so as to use the alternate method as much as possible; and this requires that the back of the pedal board shall be as available as the front.

The diversities of the arrangements of different organs present difficulty. The best players take a certain time to master the arrangements of a strange instrument. With a view to the introduction of uniformity a conference of the subject was arranged by the College of Organists in London, and a series of resolutions and a series of recommendations were published which deserve attention (1891), though they have not been adopted. We may mention that the parallel coupler, which was recommended for the pedal board, and 2½ in. for the scale. The positions of the stops of the various organs were to be as follows:

<table>

The order of compositions, &c., from piano to forte was to be in all cases from left to right. The groups of compositions were to be in the order from left to right—piano, swell, couplers, great. The swell is always the first stop, and the organ does not play unless the swell is at least partly open.

The position of the pedal board with reference to the keys. The height from the middle of the pedals to the great organ keys is, however, should be 32 in. But as to the forward position there is a difference. The resolutions said that "a plumb-line dropped from the front of the great organ sharp keys falls 2 in. nearer the player than the front of the centre short key of the pedal board." The old arrangement gave 1½ in. for this distance. But it is thought that the change has not gone far enough, and 4 in. has been found preferable. There is scarcely any single arrangement which is so important for the comfort of the player as having sufficient space in this direction (fig. 14). The second matter is the provision of some other means of acting on the swell than by the swell pedal. The use of the swell pedal is inconsistent with the proper use of both the pedal keys; and it is no doubt that incorrect habits in this respect are commonly the result of the English use of the swell pedal. In fact, players sometimes keep one foot on the swell pedal all the time, so that proper pedal playing is impossible. Arrangements have been devised by means of which a movable back to the seat can be made the means of acting on the swell. The first recommendation of the College of Organists illustrated the requirement: it was, that the consideration of organ-builders may be directed to the widely-expressed desire for some means of operating on the swell in addition to the ordinary swell pedal.

G. Cooper had a movable back to the seat of the organ at St Sepulchre's, London. The swell was opened by leaning back, so that it could only be used when the swell was coupled to the great. The writer has had an organ for more than twenty years in which the movable back is provided with a strap, passing over one shoulder and buckling in front. It opens the swell when the player leans forward. It is most valuable, particularly in such things as accompanying the service. The emphasis required is obtained when wanted without taking the feet from their other duties. Young people pick it up easily; older people have difficulty.

As an example of an organ of a complete but not enormously large character, we give the details of the organ at St George's Chapel, Windsor, which was rebuilt by Messrs Gray and Davison, according to Sir Walter Parratt's designs, in the year 1883.

One swell pedal controls two sides of the swell box. The other controls the box in which the orchestral oboe is placed. The vox humana is in a box which is always shut, inside the swell box.

History of the Modern Organ.

The history of the ancient organ is dealt with in a separate section below. The first keyboard is said to have been introduced into the organ in the cathedral at Magdeburg about the close of the 11th century. There were sixteen keys, and a drawing exists in a work of the 17th century \(^1\) which purports to represent them. They are said to have been an ell long and 3 in. broad. The drawing represents a complete octave with naturals and short keys (semitones), arranged in the same relative positions as in the modern keyboard. In early organs with keyboards the keys are said to have required blows of the fist to put them down. In these cases probably sounding the notes of the plain song was too difficult to be accomplished.

As to the precise times and conditions under which the keyboard assumed its present form we know nothing. It is commonly said that the change to narrow keys took place in the course of the 14th century, and the semitones were introduced about the same time.

Many examples of organ keyboards still exist, both in England and on the Continent, which have black naturals and white short keys (semitones). The organ in the church at Heiligenblut in Tirol had in 1870 two manuals, one having black naturals and white semitones, the other white naturals and black semitones. In this organ the stops were acted on by iron levers which moved right and left. It had a beautiful tone; it possessed a reservoir bellows of great capacity, and was altogether a remarkable instrument. Harpsichords with black keyboards also exist.

The mode of blowing practised about the time of the introduction of the first keyboard appears to have been that which ultimately developed into the method still generally used in Germany. There were a great many separate bellows, each like a single bellows, but provided with a valve, so that the wind could not return into the bellows. One man had charge of two of these. Each foot was attached to one bellows, and the blower held on by a bar above. It was possible, by raising each of the two bellows in turn and then resting his weight upon it, to produce a constant supply of wind with the pressure due to his weight. A great many such bellows were provided, and it seems that each pair required one man; so that great numbers of blowers were employed. A slight modification is enough to change this method into the German one. Instead of fastening the feet to the bellows and pulling them up, the blower treads on a lever which raises the bellows. The bellows being loaded then supplies the wind of itself. The bellows thus used have diagonal hinges, and various expedients are employed to make them furnish steady wind. But the English system of horizontal reservoirs and feeders appears far superior.

The invention of the pedal may be set down to the 15th century. About that time the organ assumed on the Continent of Europe the general form which it has retained till lately. The German pipework, more especially in Germany, this may be described generally as having a compass of about four octaves in the manuals and of two octaves in the pedal, with occasionally extra notes at the top in both, and frequently "short octaves" at the bottom. German short octaves are as follows. The manual and pedal appear to terminate on E instead of C. Then the E key sounds C, F = F, F♯ = D, G = G, G♯ = E, and the rest as usual. There were often three, sometimes four, manuals in large organs.

\(^1\) Praetorius, *Theatrwm Instrumentorum.*

The character of all these was in general much the same, but they were more softly voiced in succession, the softest manual being sometimes spoken of as an echo organ. There are one or two examples of the echo as a fourth or fifth manual in England at the present time, in organs which have been designed more or less under German inspiration. The old echo was long ago superseded by the swell in England.

A few ancient cases survive in a more or less altered condition. Of these the following are worthy of mention, as bearing on the question of date.

- **Sion (Switzerland).** Gothic. A small instrument. 1390
- **Amiens.** Originally Gothic. Large, with 16-ft. pipes. 1429
- **Perpignan.** Gothic. Large, with 32-ft. pipes. 1490
- **Lübeck.** One of the finest Gothic organs in Europe. 1504 (or, according to Hopkins, 1518).

In all these cases are sufficiently preserved to make it almost certain that pipes of the same lengths were originally employed. The actual pipes are generally modern. Shortly after this date we find Renaissance cases. At La Ferté Bernard (dep. Sarthe) part of the substructure is Gothic, and is known to be of date 1501; the organ above is Renaissance, and is known to be of date 1536. At St. Maurice, Angers, an organ was built in 1511, with Renaissance case, two towers of 32-ft. pipes, 45 stops, and a separate pedal. An account of the instrument is given in the *Procès verbal* of 1533 furnishes good evidence. In the 16th century, therefore, the organ had attained great completeness, and the independent pedal was general on the Continent.

We cannot follow the history of German organs through the intervening centuries; but we propose to give the items of one of the principal organs of the Silbermanns, the great builders of the 18th century—namely, that standing in the Royal Catholic Church, Dresden. Without being an enormously large instrument it is complete in its way, and gives a very good idea of the German organ. The account is taken from Hopkins. The date is 1754.

- **Manuals—** C to d'''' in alt.  Pedal—C to tenor e.

**Compass.**

**German organs.**

The chief difference between English organs and those of the Continent was that until the 16th century the pedal was absolutely unknown in England. The heavy bass given by the pedal being absent, a lighter style of voicing was adopted, and the manuals were usually continued down below the 8-ft. C so as to obtain additional bass by

\(^2\) The writer heard this instrument as a boy, and has a very pleasant recollection of the general effect.

---

\(^1\) Praetorius, *Theatrum Instrumentorum.*
playing octaves with the hands. Thus the old organ (date 1697) of Father Smith in St Paul's Cathedral had manuals descending to the 16-ft. C (C₁), with two open diapasons throughout. Green's old organ at St George's, Windsor, had manuals descending to the 12-ft. F, also two open diapasons throughout, no G₂. But the more usual practice was to make the manual descend to the 10½ G, leaving out the G₂. At the Revolution most of the organs in England had been destroyed. Shortly afterwards Bernard Smith, a German, commonly called Father Smith, and Thomas and René Harris, Frenchmen, were largely employed in building organs, which were wanted everywhere. Father Smith perhaps had the greatest reputation of any builder of the old time, and his work has lasted wonderfully. There is a list in Rimbault of forty-five organs built for churches by him. The list of René Harris is scarcely less extensive.

The most important step in the development of the old English organ was the invention of the swell. This was first introduced into an organ built by two Jordans, father and son, for St Magnus's church near London Bridge, in 1712. Burney writes (1771):—

"It is very extraordinary that the swell, which has been introduced into the English organ more than fifty years, and which is so capable of expression and of pleasing effects that it may be well said to be the greatest and most important improvement that was ever made in any musical instrument, should be utterly unknown in Italy; and now I am on this subject, I must observe that most of the organs I have met with on the Continent seem to be inferior to ours by Father Smith, Byfield or Snetzler, in everything but size! As the churches there are very often immense, so are the organs; the tone is indeed something that softened and refined by space and distance; but, when heard near, it is intolerably coarse and noisy; and, though the number of stops in these large instruments is very great, they afford but little variety, being for the most part duplicates in unisons and octaves to each other, such as the great and small 12ths, flutes and 15ths; hence in our organs, not only the touch and tone, but the imitative stops, are greatly superior to those of any other organs I have met with."

(Ass to these opinions, compare what is said on great organ open diapasons above.)

In the course of the 18th century most of the old echoes were altered into swells, and the swell came into almost universal use in England. The development of the swell is inseparably associated with the peculiar quality of English swell reeds. These swell stops had originated during the development of the swell. We hear of "the good reed voice" named Hancock, who worked with Cranz, changing echoes into swells. However it originated, the English swell is beautiful when properly made. The original swells were usually short in compass downwards, frequently extending only to fiddle g. It is only lately that the value of the bass of the swell has been properly appreciated. Short-compass swells may be said to have now disappeared.

The organ in St Stephen's, Coleman Street, was probably nearly in its original condition at the date when it was described by Hopkins. It was built by Avery in 1775. At all events the following arrangements might very well have been the original ones. The pedal clavier without pipes is no doubt a subsequent addition, and is omitted.

**Present day organs.**

**Avery's old English organ.**

This gives an excellent idea of the old English organ. There are several different accounts of the introduction of pedals into England. It took place certainly before the end of the 18th century, but only in a few instances; and for long after the usual arrangement was simply to provide a pedal clavier, usually from F or G₁ to tenor c or d, which totalled down the notes of the great organ. Unison diapason pipes (12-ft.) were occasionally used. In one or two cases, as in the transition states of the old organ at St George's, Windsor, a 24-ft. open diapason was employed as well as the unison stop. But a more usual arrangement, of a most objectionable character, was to combine the G₁—c pedal-board with a single octave of so-called pedal-pipes, extending from the 16-ft. to the 8-ft. C; so that, instead of a uniform progression in ascending the scale, there was always a break or repetition in passing C.

About the middle of the 19th century it began to be generally admitted that the German arrangement of the pedal was better, and the practice gradually became general of providing a complete pedal-board of 2½ octaves (C—f''), with at least one stop of 16-ft. tone throughout, even on the smallest organs that pretended to be of any real use. The study of the classical works of Bach and Mendelssohn went hand in hand with this change; for that master could not work without the change, and yet the desire for the study was one of the principal motives for it. In the meantime Bishop, an English builder, had invented composition pedals, which so greatly facilitate dealing with groups of stops. About the same time (1850) the mechanics of the organ were advanced by the general introduction of the pneumatic lever into large instruments; the whole mechanism of the organ was revolutionized by Willis's improvements; and the organ-builders of England, having obtained from the Continent the fundamental ideas necessary for completeness, advanced to a point at which they appear to have been decidedly ahead.

In the early part of the last quarter of the 19th century, the future of the English organ appeared to be one of great promise. Much confidence was felt in the brilliant combinations of Willis's mechanism. The employment of electricity had reached a certain stage, and the necessary fundamental mechanism, under the name of the electro-pneumatic lever, was to be obtained in a practical form. Several new devices were in the air, by means of which the control of the various valves was accomplished by the action of wind, traversing channels, with complete abolition of trackers, and even of stop slides; and Willis's classical mechanisms, including those for acting on stop slides pneumatically without direct mechanical connexion between slide and handle, were almost universally adopted in large organs. The delicate device of pneumatic lever on pneumatic lever, by which alone the small electromagnetic impulses available could be made to do heavy work, had obtained recognition. If there was an occasional failure, it was thought to be no more than might be expected with work of a novel and delicate character. And it was confidently expected that these devices would, in time, with the improvements associated with practical use, come to be reliable. This expectation has not been realized. The objections to the modern pneumatic, and still more to the electromechanical machinery, are of two kinds—noise and inefficiency.

**Noise in the Key Action.**—We take as the standard of comparison the old tracker organ, without pneumatics. There was always a certain amount of difficulty in opening the stops of Willis himself during his lifetime, and still more in the best instruments of the present day, the noise of the key action is judged to be as bad as in the old tracker organ. The pneumatics have to be driven by a powerful wind; the consequence is they get home with a knock.

**Noise in the Stop Action.**—If in a large instrument with pneumatic drawstop action one of the compositions which affects several stops is put into action, the resulting noise is like a hammer, which is caused by the pneumatics getting home under the powerful force employed. This is much worse than anything there was in the old organ.

**Inefficiency in the Key Action: Delay and Cyphering.**—This chiefly shows itself in delay, both at the depressing and at the recovery of the key. Some of the causes are the size of the pneumatic bellows, which takes time to fill and time to empty; and, very often, defective regulation of the valves. The regulation of the valves is an art
in itself, and it is often the case that the performance in this respect can be greatly improved by going over the regulation. The test is the possibility of executing shakes and repetitions. It is quite common to find mechanism by the firstorgan-builders of the day on which shakes or repetitions cannot be executed. Transmission is also specially liable to cause delay. In divided organs the swell is usually on the far side from the keys, and the pneumatic transmission tubes pass it under the floor. The swell touch is then considerably worse than the great. In all large organs in which the action can be isolated, the pulse takes to traverse the transmission tube with the velocity of sound. And if a pneumatic bellows has to be filled at the far end the delay will be more. Some of the delay experienced in large buildings may be due to the bellows; but, considering the necessity for perfect pressure, and maintaining the vibrations of the air in the building. This should, however, have been the same with the old tracker action; and the opinion of old players is unanimous that they never experienced any perceptible delay. Of course, all bed and repetition are the only real tests so far as the action is concerned.

Inefficiency in the key action also takes the form of “cyphering,” i.e. a note sticks down. With the old tracker organ this could generally be avoided without much difficulty by working on the action, and with the separate pneumatic lever something could be done. But the modern types of elaborated action are entirely enclosed in wind-chest and sound-board. It was always foreseen that these types would be dangerous, unless separate vessel and separate action were kept up. When a note sticks, there is no way of curing it except to get at the side of the wind-chest, or to remove all the pipes belonging to the note. A case happened recently where, during a performance on an organ by a first-rate modern tracker action, the bellows cut out. To cure the fault and get the pipes belonging to the note were removed. In the second the last three pages of a Bach fugue were played with a note cyphering the entire time; and such cases are of frequent occurrence.

The well known, and often quoted, is that the performer provided is insufficient to move the stop slide. As there is no direct connection between slide and handle, nothing can be done but to get inside the organ and move the slide by hand. A case has recently occurred where a teacher insisted that the organist had not been properly cared for, got one of the slides stuck while in use. The organ was locked, so nothing could be done. The same happened to another slide a couple of days later. It is also an everyday experience that the same practical deficiencies are insufficient to move the stops, sometimes they move the stops about halfway, when a sort of wall is heard.

One practical result is — where an organ is not too large to be dealt with by the old mechanical methods, there is much to be said for one to the key in the other. The result is worth while to mention two suggestions by which these imperfections in large organs might be reduced to a minimum. For blowing, motors for stop action, &c., the old mechanical reasonable, the construction of an accumulator system, at pressures of say 120 lb. on the square inch. The pumping of the system would be done by external power (electricity, gas, oil or steam), quite away from the building containing the organ. The blowing would be done by the hydraulic or pneumatic stop-action, and the wind would be kept for the stops. The small hydraulic motors attached to the stop slides, &c., might have almost infinite power and be perfectly noiseless. The key-work should be pneumatic and should use Willy’s floating lever. This principle should be hydraulic, with the floating lever, as also the action of the back of the seat if employed for opening the swell. The effect of the floating lever is that the movement of the lever corresponds exactly with the movement of the part connected with key and pedal. The connexion with the key would have a regularity so that the lever would begin to move a little later than the key, the regulation being adjusted by trial so that to avoid shakes and repetitions.

The principle of the floating lever is the same as that of the steam steering gear in ships. The control of the power is attached to the floating centre. It is always such that the movement of the work brings back the floating centre into its standard position, and it acts like a fixed centre with added power. The regulation of the instrument, it is desired to make two protests. Firstly, the organ chamber a monstrosity. Shutting up the organ in a confined space is simply throwing money away. An organ of a quarter the size would do the work better if not shut up in an organ chamber. A second objection is that it is customary to separate the different parts of an organ, putting the pipes of the bellows, great and swell perhaps in different places at a distance from one another, and the soft choir organ, which should be close to the great, and near the swell, as it were in the same position where it cannot be heard at all and is useless for accompaniment. The parts of an organ so dispersed will not give a tone which blends into a whole. The practice is undesirable. The divided organ with pneumatic or electric transmission is to be avoided for all reasons.

General Remarks on Organ Treatment

The organ probably presents more difficulties than any other instrument in the way of a sound elementary mastery. A person of ordinary capacity may work at years before being able to pass the examinations for moderate difficulty with confidence and correctness. The special difficulty appears to be chiefly mental, and arises from the number of things that have to be thought of simultaneously. It does not lie in the execution — at least not chiefly; for to play a hymn-tune correctly, the bass being taken with the pedals, the tenor with the left hand, and the two upper parts with the right, it is a matter in which there is no execution required; but it is of great difficulty to an inexperienced player. Other distributions of parts such as bass with pedals, treble with right hand on a solo stop (e.g. clarinet), two inner parts with a soft open diapason, or something of the kind — are of much greater difficulty in the first instance. Another distribution is bass with pedals, melody with a Reed or soft combination in the tenor with left hand (an octave below its true pitch), inner parts with right hand on a soft open diapason, or something that balances. This is of far greater difficulty, as it requires rearrangement of parts to avoid those faults of inversion the avoidance of which is known as double counterpoint. All this can be practised with common hymn tunes; but the performer which can do these things with ease is the true organist, the ideal organist.
the most sparing and careful employment of them is undesirable. Expression is not possible unless the stops are enclosed in a swell box—a most desirable arrangement. In all cases bury is to be avoided. A calm steadiness, a minute finish of all the phrasing, forms most of the difference between first- and second-rate players.

With reference to the general treatment of modern music we quote the preface to Mendelssohn's Organ Sonatas: "In these sonatas very much depends on the correct choice of the stops; but, since every organ with which I am acquainted requires in this respect special treatment, the stops of given names not producing the same effect in different instruments, I have only indicated certain limits, without specifying the names of the stops. By fortissimo I mean the full organ; by pianissimo usually one soft 8-foot stop alone; for forte, full organ without some of the most powerful stops; by piano, several soft 8-foot stops together; and so on. In the pedal I wish everywhere, even in pianissimo, 8-foot and 16-foot (tune) together, except where the contrary is expressly indicated, as in the sixth sonata [this refers to a passage where an 8-foot pedal is used without 16]. It is therefore left to the player to combine the stops suitably for the different pieces, but particularly to see that, in the simultaneous use of two manuals, the one keyboard is distinguished from the other by its quality, without forming a glaring contrast."

Importance is attached to the above directions as to single stops. The habit of mixing up two or more stops unnecessarily results in the loss of the characteristic qualities of tone which reach their highest value in single stops.

A habit is prevalent of using couplers in excess. One hears the swell coupled to the great during an entire service. The characteristics of the two manuals, which, separated, lend themselves to such charming contrasts, are lost in the mixture, just as the characteristics of single stops are lost when employed in groups. It is common to see an English organist keep the right hand on the swell pedal and hop about with the left on the pedals. This cannot be called pedal-playing. Both feet should be used, except where the swell pedal is actually required. It is a common habit to hold a note down when it should be repeated. It should be struck again when indicated. The repetition is a relief to the ear.

The older organists commonly filled up their chords, striking pretty nearly every concordant note within reach. The effect of this was in many cases to destroy effects of parts, or effects of restraint leading to contrasts intended by the composer. There is a well-known case of a climax about a line before the end of Bach's "Passacaglia." Here there is a pause on a chord of four notes; one low in the bass (pedal); two forming a major third in the middle; and one high in the treble. Some players fill in every concordant note within the reach of both hands. Others consider the effect of Bach's four notes superior. The writer thinks that the average listener prefers the full chord, and the polyphonic character of the thin arrangement of parts. Of course, when the manuals are used separately, the use of the pedal is also sometimes intended to lead up to a contrast which is lost if the pedal is introduced too soon.

Contrast and variety are essential elements in organ effects. A suitable phrase repeated on solo stops of different characters; a see-saw in a series of rhythmical chords between two manuals of different characters—contrasts generally—are charming when suitably employed. Phrasing we cannot describe here. It is just as important in the organ as in any solo instrument, or in song.

There has been a tendency to attempt too much in the imitation of orchestral instruments. While such stops as good flutes and good imitations of wind instruments have their value, the imitation of stringed instruments and of the orchestra in general is undesirable. The organ's own proper tones are unequaled, and it is a pity to make it a mere caricature of the orchestra.

The writer has had the opportunity of inspecting two of the installations known by the name of J. Hope-Jones; both under the care of an able enthusiast in the matter, Mr. Collins, of Edinburgh. The Hope-Jones system consists of two parts: a mechanism, and a system of pipe-work. These must be considered separately. The mechanism is entirely electric. One example consisted of an application of this mechanism to a fine organ by Willis. The conditions were as favourable as possible, with temperature regulation and constant use. Yet even in this case the contacts failed occasionally. The difficulty about repetition appeared to have been entirely got over, the performance being satisfactory when the contact was in good order. These contacts appear to be the weak part of the system. All the mechanism, couplers and all, is worked by means of these contacts. With the care which is taken no difficulty is found in getting the arrangement to work in the case of the Willis instrument. The system is very complicated, with double touch couplers throughout, by means of which a solo can be effected on one manual by pedals alone. The study of the double touch appears very difficult. Stop handles are both away with. They are replaced by rockers, the faces of which are about the size of small railway tickets. The appearance is as if the surface where the stop handles would be was plastered over with these rockers. They turn on a horizontal axis through the middle, and a touch of the finger at top or bottom opens or closes the stop. The other instrument was Hope-Jones thought, pipes and mechanism. The curator was the same as in the case of the Willis instrument. But, the hall being little used, there was no temperature regulation, and very little use. The state of the mechanism was inferior, the contacts failing freely. It could not be regarded as an admissible mechanism from the writer's point of view. As to the pipe-work, the effect was remarkable; but it could not be regarded as genuine organ work, as the player admitted. Our requirement in the matter of action is a perfectly unfailing connexion between key and pipe. And in this respect we adhere to a preference for the old tracker action, where possible. Anything that leaves a possibility of failure in the connexion we regard as inadmissible.

The writer desires to acknowledge his obligations to Sir Walter Parratt for much assistance in the preparation of this article.

(R. H. M. B.)

**History of the Ancient Organ.**

The earliest authentic records of the organ itself do not extend beyond the second century B.C., but the evolution of the instrument from the Syrinx or Pan-pipe goes back to a remote period. The hydraulic and pneumatic organs of the ancients were practically the same instrument, differing only in the method adopted for the compression of the wind supply; in the former this was effected by the weight of water, and in the latter by simple primitive expedient of working the bellows by hand or foot. What is known, therefore, of the evolution of the organ before hydraulic power was applied to it is common to both hydraulic and pneumatic organs. The organ of the ancients was a simple contrivance, consisting, in order of evolution, of three essential parts: (1) a sequence of pipes graduated in length and made of reed, wood or bronze; (2) a contrivance for compressing the wind and for supplying it to the pipes in order to make them speak, the ends of such pipes as were required to be silent being at first stopped by the fingers; and (3) a system for enabling the performer to store the wind and to control the distribution of the supply separately to the several pipes at will. The pipes of the syrinx were the prototypes of No. 1; the bellows and the bag-pipe—which was but the application of the former to the reed—foreshadowed No. 2. The third part of the organ was composed of contrivances and common objects used by carpenters, such as boxes having sliding lids running in grooves, levers, &c.

It seems probable that the syrinx was recognized by the ancients as the basis of the organ. Hero of Alexandria, in his description of the hydraulic organ, calls it a syrinx. Philo of Alexandria (c. 200 B.C.), mentioning the invention of the hydraulic(us) by Ctesibius,
says, "the kind of syrinx played by hand which we call hydraulis."

The fact that the syrinx was an assemblage of independent stopped pipes, which in their original condition could not be mechanically blown, since the movable lip of the player used to direct the air stream against the sharp edge of the open end of the pipes and is necessarily, is no bar to the suggested derivation. Wind projected into a pipe can produce musical sound unless the wind is first compressed and the even flow of the stream be interrupted and converted into flutterings. If a person would produce these pulses in an organ-pipe, it is necessary to use some such contrivance as a reed, flue or whistle mouthpiece (q.t.).

In the earliest organs there is no doubt that the pipes consisted of lengths of the large reed known as sabaus used for the syrinx, but cut and inserted into open flue-pipes. Instead of cutting off the sharp edge of the pipe by the action of the bellows. A narrow fissure was made through the knot near the front of the pipe, and above it a horizontal slit was cut in the reed, the two edges being bevelled inwards. When the wind has escaped, it is not difficult to find that this has left the holes in the lid, and the current, being divided by the foot of the pipe, became compressed and was forced through the fissure in the knot. It then ascended the pipe in an even stream, as yet silent, until the force of the wind by its compression on the reed turned it into the sharp edge or lip of the notch, which produced the regular flutterings or pulses requisite for the emission of a note. The very simplicity of this process dispenses with any difficulty in accepting the syrinx as an improved pipe organ, and the conversion of a syrinx pipe is, in fact, a simpler and more natural expedient than the more elaborate construction of a wooden flue-pipe.

In order to convert the syrinx into a mechanically played instrument, it is only necessary to add a mechanism of controlling the escape of the wind through any given pipe. We have two pottery figures of musicians playing on primitive organs in the next stage of development, namely, with bellows, and a description in the Talmud. The quotation as given by Blasius Ugoannis states that the instrument known as the Magrepho d'Aruchin, or the Magrepho of Sabaus, has its reed placed under the hand, and there are rows of pipes and was blown by bellows. It had, besides, holes, and small sliding stop or any other hole in the pressure of the organist; the vent-holes being open, a wonderful variety of sounds was produced. Such organs were fastened to Dardanus might also be consulted in this connexion. In Tarsus in Asia Minor pottery and coins dating from c. 200 B.C. were excavated by W. Buckland Barker, and amongst them is the fragment of a syrinx. The vessel piped upon an instrument, the teapot to his breast, and having seven pipes set in a rectangular wind-chest, in the centre of which appear to be two bellows of unequal sizes. Unfortunately both drawing and sculpture are so vague: nevertheless, there is no room for doubt that this is a pipe organ, perhaps without sliders or keys, the pipes being opened at the top end, nearest the player's mouth, by the fingers, supposing that there was only one bellows. Another piece of pottery from Tarsus, discovered in the Dominus' chamber of the Church of St. Mary of St. Mary, M. M. Maville and V. Langlois, and preserved in the Louvre, shows the back of an organ having fifteen pipes. Two models of organs of more recent date also show the construction of that found by Mr. H. D. Budge in Chinese Turkestan on the site of ancient Khotan a (fig. 1) represents an instrument having the instrument's bellows in the front, without being operated by the organist himself or his breast; both hands seem press buttons which might be bellows, and there are seven pipes below the bellows. The other instrument (fig. 2) is of Roman origin, and forms part of the decoration on a wooden fragment of a page from the 2nd century A.D. of Italy, now preserved in the collection of M. Emilien Dumas de Sommières. The subject represented in the

medallion is an amphitheatre, and in the centre a pneumatic organ with bellows is plainly visible (fig. 2).

This brings us to a point in the history of the organ when the existence of the hydraulic organ can no longer be ignored. Some writers consider that the invention of the hydraulic organ in the 2nd century B.C. by Ctesibius of Alexandria constitutes the invention of the organ, and that the pneumatic organ followed as an improvement or variety. Such an assertion would seem to be untenable, and we must again see what has been said above. It is most improbable that a man busy with the theory and practice of hydraulics would invent a highly complex musical instrument in which essential parts lying outside the realm of his knowledge would be a necessity, or that the flue-pipes, the balanced keyboard, the arrangements within the bellows, and that it is only the case of the wind, are all in a highly developed state; it would be the case for which no parallel exists in the history of mechanical instruments, all of which have been developed and improved through the ages. On the other hand, given a pneumatic organ in which there are many small海湾, and with pipes, the little bellows worked unsatisfactorily, an engineer would be prone to see an opportunity for the advancement of such an actuation of the wind as the

There are two detailed and duly accredited descriptions of the hydraulis extant, both of which presuppose the existence of a pneumatic organ. One is in Greek by Hero of Alexandria, 1 said to be a part of his Syrinx, the other in Latin by Vitruvius (De Arch.

lib. x. cap. iii.). In both accounts, Hero is made to draw a bellows now lost. Mr. Woodcroft states that in each MS. the diagrams are said to have been copied faithfully, and that on consulting four MSS. and three early printed editions he found that the mechanical principle described in each case is the same as that of the organ and the arrangement of the pipes which vary according to the fancy of the architect.

The principle of the hydraulis, which remained a complete mystery until the 19th century, is now well understood. Representations of Roman hydraulic organs abound, but they were not always identified as such. The front of the organ (the performer sat or stood at the back) was invariably represented, there had been no indication of this before the pipes were made to sound. A clue was furnished by a little baked clay model of an organ, and parts of the performer, excavated in 1889 on the ruins of Carthage and now preserved in the Musee Musique, attached to the cathedral of S. Stefano, Rome. The model represents a pipe organ with 12-14 pipes, the whole measuring 24 in. (figs. 3 and 4), modelled by Possessori, a potter working at the beginning of the 2nd century A.D., whose name appears on the front below the ends of the sliders, is so accurately designed that it seems to be in every point with the description of the instrument of Hero and Vitruvius. The number and relative sizes of the three

1 Tertullian (De anima, 14) names Archimedes, who is probably an error. See in this connexion Hermann Degering, who devotes considerable space to the question, Die Orgel, ihre Erfindung und ihre Geschichte (Munster, 1905).

2 See The Pneumatica of Hero of Alexandria, translated from the original Greek by Bennett Woodcroft (London, 1851), with diagrams.

3 Edward Bulle Die musikalisichen Instrumente in den Miniatures des Frenken Mitters, p. 228 (1903), p. 55. Note 1 corrects this as an error, assigning Hero's activity to the beginning of our era, in case the description by Vitruvius would be the earlier in spite of the fact that the hydraulis, as he describes it, was improved on that of Hero, i.e., registers, and two pumps instead of one, and that he omits to explain the purpose for which water is used. Bulle gives as his authority Diels, "Das physe, System des Strabon," p. 291, in Berliner Monatsberichte (Feb. 1848).

4 For an exhaustive and careful compilation of these editions, and of the literature of the hydraulis generally, see Dr. Charles Maclean's article, The Principle of the Hydraulis Organ, "Inter. Mon. Arch. Med.," vi. 2, 1893, 183-237, also John W. Warman, Bibliography of the Organ, who, however, takes the erroneous view that the medieval editions of Vitruvius and Hero may be taken as evidence that the instrument itself was in use until about the middle of the 17th century. See Proc. Mus. Assoc. (1903-1904), p. 49.

5 The present writer was apparently the first in England to draw attention to this identity by introducing the drawing from the Utrecht Palster and the model of the Carthage Organ, &c. See Music (London, Sept. 1898), p. 438.
rows of pipes, gauged by the remains of the organist, give the requisite compass for the production of the six Greek scales in use at that date. A working reproduction based on the proportions of the remains of the organist, but at half scale for the sake of portability (the real organ must have measured 10 ft. in height by 4 ½ ft. in width), was successfully carried out by the Rev. F. W. Galpin in 1900-1901 by the help of photographs and of the text from Vitruvius.

The principle of the hydraulis is simple. An inverted funnel of bell of metal, standing on short feet and immersed in water, with the altar-like receptacle forming the base or pedestal, communicates with a pipe, with the wind-chest, placed above it. When the air is pumped into the funnel by the bellows the air in a state of compression in the funnel, whence it travels through the pipe into the wind-chest. The rest of the process is common also to the pneumatic organ.

As there are two pumps working alternately, these organs remain unchanged, until by pressure on a key a slider under the aperture leading to the pipe, the compressed air is afforded an exit through the latter, thus producing the desired note. It will be seen, therefore, that this organ acts on the air as a compressor exactly in the same manner as lead weights are used on the wind reservoir of modern pneumatic organs. The discovery of the Carthage model was of the greatest importance to the history of the keyboard (q.v.), for it proved beyond a doubt the use at the beginning of our era of balanced keys (seen in front of the organist) on the principle described by Vitruvius. What appears to be a second keyboard with smaller keys on the side of the hydraulis labelled Possessoris (fig. 4) is, simply the ends of the sliders, which are pushed out or drawn in by the action of the keys.

The principle of the hydraulis made it possible to construct large organs of plentiful tone more suitable for use in the arena than the small pneumatic instruments, but the hydraulis organ never entirely supplanted the pneumatic, which was probably not so imperfect at the beginning of our era as has been thought, since it outlived the former and seems to have differed from it only in the matter of pressure. The hydraulis, on the other hand, has the drawback that it cannot damp the instrument being of a serious nature; it was also unwieldy and difficult to carry about.

Of the pneumatic organ in portable and portable form, traces have been found during the palmy days of the Roman empire, and the art of organ-building, of which the organ in fig. 5 is an example, never seems to have quite died out during the decline of classic Rome and the dawn of Western civilization.

This illustration is derived from a 4th- or 5th-century slab in the church of St Paul extra muros at Rome. It is evident that the hydraulic organ was widely known and used in the East during the early centuries of our era, but it never won a footing in the

West, although a few solitary specimens found their way into the palaces of kings and princes. On account of its association with the theatre, gladating crowds and pagan amusements of corrupt Rome, it was placed under ban by the Church. The ignorance and misinformation displayed by the popular writers and miniaturists of the early and late Middle Ages leave no room for doubt that the instrument itself was unknown to them except from hearsay.

Venice seems to have been famed for its organ-builders during the 9th century, for Louis le Débonnaire (778-840) sent there, it is recorded, for a certain monk, Georgius Benvento, to construct an hydraulic organ for his palace at Aix-la-Chapelle.

No progress in the art of organ-building is recorded until the use of organs in the churches had long been established. The recognition of the value of the organ in Christian worship proved an incentive which led to the rapid development of the instrument.

In France and Germany the Romans must have used organs and have introduced them to the conquered tribes as they did in Spain, but the art of making them was soon lost after Roman influence and civilization were withdrawn. Pipin, when he wished to introduce the Roman ritual into the churches of France, felt the need of an organ and applied to the Byzantine emperor, Constantine Copronymus, to send him one which arrived by special embassy in 757 and was placed in the church of St Corinelle at Compiegne; the arrival of this organ was obviously considered a great event; it is mentioned by all the chroniclers of his reign.

Charlemagne received a similar present from the emperor of the East in 812, of which a description has been preserved. The bellows were of hide, the pipes of bronze; its tone was as loud as thunder and as sweet as that of lyre and psaltery. This organ must have had registers like those of the hydraulis of Vitruvius and the portable from Pompeii. In 826 we hear that his son Louis le Débonnaire obtained a pneumatic organ for the church at Aix-la-Chapelle, not to be confounded with the hydraulis installed in his palace.

The statement that the organ was introduced into the Roman Church by Pope Vitalian at the end of the 10th century, which has been generally accepted, is rejected by Buhle on the ground of insufficient proof. There is abundant evidence to show that the organ had taken its place in the churches in the 10th century, not only in England but in Germany, where the construction by monks had become so general that we find no fewer than three treatises on organ-building written by monks, followed by three more in the 11th century.

Considerable activity was displayed in England in the 10th century in organ-building on a large scale for churches and monasteries, such as the monster organ for Bishop Alphege at Winchester, which had 400 bronze pipes, 26 bellows and 2 manuals of 20 keys, each governing 10 pipes. There is also the elaborate organ presented by St Dunstan to his monastery at Malmesbury.

6 Op. cit. p. 61, note 2, where the evidence is carefully sifted.
7 (1) by Notker of St Gallen (see Hattenger, Denkmäler, Bd. iii. pp. 588 seq.; Hugo Riemann, Studien z. Gesch. der Notenschrift, 1903); (2) Martin Gerbert, ib. ix. p. 100 seq. (3) by Bernoullius (see Gerbert, ib. iii. pp. 318 and 325). The third is an anonymous 9th-century tract, the earliest of all, De mensura & figuratis, giving only the proportions of organ pipes. M.S. Lat. 12949 fol. 43. Paris Bibl. Nat. has a reproduction by Buhle, op. cit. p. 104 (Latin only).
Earl Elvin gave money "triginta libras" to the monastery at Ramsay for copper pipes for a great pneumatic organ to be played on high days and holidays. The great activity recorded in the 12th and 13th centuries in Germany is probably due to the influence and teaching of Byzantine masters during the 9th century. Pope John VIII. (872-880) applied to Bishop Anno of Freising to send him an organ and an organist. 

Organists were installed in Cologne (11th century), Halberstadt, in Erfurt, in Aachen, in Andernach, in Stettin, in Petersberg, Cologne Cathedral, 11th century. The rest of the literary and archaeological material—treatises, monuments, miniatures—available during the later middle ages yields very scant authenticated information as to the progressive steps which lie between the 12th-century organ as described by Theophilus and the large church organs of the days of Praetorius (1618).

The keyboard is the principal feature concerning which miniatures offer any evidence. Here and there a 13th-century miniature gives a hint of balanced keys on small portative organs which already abounded during that and the next century. The Bernese monk in his treatise on the organ, to which reference was made in the note above, clearly describes balanced keys, depressa lamina, pressed down, not pulled out, as were those mentioned by Theophilus; his description conforms strictly with that of Hero, which suggests that he was borrowing from classical authorities rather than describing an actual instrument with which he was well acquainted, an expedient to which most cases resemble the white keys of the modern piano forte. There is no miniature on record in which the fist action on the keys is indicated, the performer during the 10th, 11th and 12th centuries being depicted in the act of drawing out the stop-like sliders—as for instance, in the 12th-century manuscript Bible of Etienne Harding at Dijon (fig. 6), where the organist is playing the notes D and F, the sliders being lettered from C to C. From the 13th century the keys are shown pressed down by means of one finger or of finger and thumb, as in MS. said to have been compiled for Alphonso XIII. (c. 1237), known as the Cantigas de Santa Maria, a portative is shown having balanced keys, one of which is being lightly pressed by the thumb, the instrument resting on the palm—while the left hand manipulates the bellows.

The keys themselves varied in shape, being either like a T; a wide rectangle, with or without the corners rounded off, or a narrow rectangle. The earliest instance of chromatic keyboard is that of the organ at Halberstadt, which has been restored in 1495. An inscription on the keyboard states that it formed part of the original organ, which had the semitonal arrangement of keys.

It must not, however, be inferred from these isolated cases that balanced keys were general from the 13th century, nor that thechromatic keyboard was not known to the 14th. The St Cecilia in the altar-piece in Ghent by the brothers Hubert and Jan van Eyck (15th cent.) is represented as playing a modern-looking keyboard.

A picture by Fra Angelico (15th cent.) in the National Gallery shows a portative with accidents. It will probably be found that the earliest development of the organ took place in Germany and in the Netherlands.

**ORGANISTRUM**, the medieval Latin name for the earliest known form of the hurdy-gurdy (q.v.). The organistrum was large enough to rest on the knees of two performers sitting side by side, one of whom turned the crank setting the wheel in motion, while the other, the artist, manipulated the keys. The word organistrum is derived from organum and instrumentum; the former term was applied to the primitive harmonies, consisting of octaves accompanied by fourths or fifths, first practised by Hucbald in the 10th century. This explanation enables us to fix with tolerable certainty the date of the invention of the organistrum, at the end of the 10th or beginning of the 11th century, and also to understand the construction of the instrument. A stringed instrument of the period—such as a guitar-fiddle, a rotta or oval vielle—being used as model, the proportions were increased for the convenience of holding the instrument and of dividing the performance between two persons. Inside the body was the wheel, having a tire of leather well rinosed, and working easily through an aperture in the sound-board. The three strings resting on the wheel and supported by levers on a bridge of the same height all revolved, and in the earliest examples the wooden tangents taking the place of fingers on the frets of the neck acted upon all three strings at once, thus producing the harmony known as organum.

The organistrum appears on bas-relief from the abbey of St Georges de Boscha (11th cent.), now preserved in the museum of Rouen, where it is played by a royal lady. The organ, which has the place of honour in the centre of the band of musicians representing the twenty-four elders of the Apocalypse in the tympanum of the Gate of Glory of the cathedral of Santiago da Compostella (12th cent.). There is also a fine example in a monument of Canter of English workmanship (13th cent.), forming part of the Hunterian collection in Glasgow University; this was shown at the Exhibition of Illuminated MSS. at the Burlington Fine Arts Club in 1908.

ORGANON (Gr. οργανον, instrument, from ὄργανον, work), the name given to Aristotle's logical treatises. They are so called because logic is itself neither a speculative science nor a practical art in the ordinary sense, but an aid or instrument to all scientific thought. Francis Bacon, regarding the Aristotelian logic as he understood it as of no avail, gave to his own treatise the name Novem Organum in the belief that he had discovered a new inductive logic which would lead necessarily to the acquisition of new scientific knowledge. Compare also Whewell's Novum Organum Renovatum and Lambeth's Neues Organon. In medieval music the term was applied in a similar sense to early attempts at improvised counterpoint i.e. a part sung as an accompaniment above or below the melody or plainsong; it consisted of 8ths and 5ths (or 4ths) added to the plainsong.

ORYG (through French from Lat. orgia, Gr. ὀργια, in derivation connected probably with ὄργανον, work; cf. Lat. oratio, to sacrifice), a term originally denoting the secret rites or ceremonies connected with the worship of certain deities, especially those of Dionysus-Bacchus. The Dionysiac orgies, which were restricted to women, were celebrated in the winter among the Thracian hills or in spots remote from city life. The women met, clad in fawn-skins, with hair dishevelled, swinging the thyrsus and beating the cymbal; they danced and worked themselves up to a state of mad excitement. The holiest rites took place at night by the light of torches. A bull, the representative of the god, was torn in pieces by them as Dionysus-Zagreus had been torn; his hallowing reproduced the cries of the suffering god. The women tore the bull with their teeth and the eating of the raw flesh was a necessary part of the ritual. Some further rites, which varied in different districts, represented the resurrection of the god in the spring. On Mount Parnassus the women carried back Dionysus-Licnites, the child cradled in the winnowing fan. The most famous festival of the kind was the orgies celebrated every four years on Parnassus by the women of Attica and Phocis. The celebration of the orgies among the Maenads or Bacchae. The ecstatic enthusiasm of the Thracian women, Κλώδωνας ή Μυκάλωνες, was especially distinguished. The wild dances, songs, drinking and other "orgastic" ceremonies which were characteristic of these rites have given rise to the use of the word "orgy" for any drunken, wild revel or festivity (see DIONYSUS and MYSTERY).

ORIA, a town of Apulia, Italy, in the province of Lecce, 25 m. E. of Taranto and 19 m. S.W. of Brindisi by rail, 540 ft. above sea-level. Pop. (1901), 8838. It occupies the site of the ancient Oris, the chief town of the Salentini, which stood in a commanding position in the centre of the peninsula of the ancient Calabria (q.v.), almost midway between Brundisium and Tarentum on the Via Appia. Strabo mentions that he saw there the old palace of the Messapian kings (vi. 3. 6, p. 283). The town contains a small museum and a fine castle of Frederick II., erected in 1227. The Doric family of Gia'ori and Rome is said to derive its name from a certain Tommaso d'Oria, who led the rebellion against Frederick's son Manfred. Much damage was done by a cyclone in 1878.

OIRIB, or OUTIB, the local name of a small South African antelope (Oribia scoparia), standing about 24 in. at the shoulder, and characterized by the presence of a bare glandular spot below the ear, the upright horns of the bucks, which are ringing for a short distance above the face, and the tufted bushy tail, of which the terminal two-thirds are black. The name is extended to include the other members of the same genus, such as the Abyssinian, O. montana; the Gambian, O. migricandata; the British East African, O. haggardi; and the Mozambique, O. petzi.

ORIEL, JOHN FOSTER, BARON (1740–1828), Irish politician, was the son of Anthony Foster of Louth, an Irish judge. He was returned to the Irish parliament in 1761, and made his mark in financial and commercial questions, being appointed chancellor of the Irish exchequer in 1784. His law giving bounties on the exportation of corn and imposing heavy taxes on its importation is noted by Lecky as responsible for making Ireland an arable instead of a pasture country. In 1785 he became Speaker. He opposed the Union, and ultimately refused to preside over the Speaker's mace, which was kept by his family. He was returned to the Irish parliament, and in 1804 became chancellor of the Irish exchequer under Pitt. In 1813 he was created a peer of the United Kingdom as Baron Oriel of Ferrand in the county of Louth, and died on the 23rd of August 1828. His wife (d. 1824) had in 1790 been created an Irish peeress, as Baroness Oriel, and in 1797 Viscountess Ferrand; and their son, Thomas Henry (d. 1843), who married Viscountess Massereene (in her own right) and took the name of Sheffield, inherited all these titles; the later Viscounts Massereene being their descendants.

ORIEL, in architecture, a projecting bay window on an upper storey, which is carried by corbels or mouldings. It is usually polygonal or semicircular in plan, but at Oxford in some of the colleges there are examples which are rectangular and rise through two or three storeys. In Germany it forms a favourite feature, and is sometimes placed at the angle of a building, carried up through two or three floors and covered with a gable roof. The oriel is also said to have been provided as a recess for an altar in an oratory or small chapel. In the 15th century oriels came into general use, and are frequently found over entrance gateways.

The origin of the word is unknown. The suggested derivation from Lat. aureolum, with the supposed meaning of a gilded chamber or room, is not, according to the New English Dictionary, borne out by any historical evidence, and early French forms —such as curseil—do not point to an origin in a word beginning with au. Du Cange (Glossarium, s.v. Oriolum) quotes Matthew of Paris (1225, Vitæ Abbatisum S. Albanii: adjacet atrium nobilis- simum in introitu, quad porticus vel Oriolum appellatur; and also a French use of 1338, where a licence to build an oriel is granted to one Jehan Bourgos. The earliest meaning seems to be a gallery, portico or corridor, and the application of the term to the oriel seems to be of later origin. The word apparently arose from such a window being in an "oriel." In Cornwall "ior" is still used of a balcony or porch at the head of an outside staircase leading to an upper story in a fisherman's cottage. The name of Oriel College, at Oxford, comes from a tenement known as Seneschal Hall or La Oire, and granted to the college in 1327. There is no trace of the reason why the tenement was so called, but it would seem that it referred to one of the earlier applications of the word, to a gallery or porch, rather than to a window.

ORIENTATION, the term in architecture given to the position of a building generally with reference to the points of the compass, and more especially (as the word implies) to that of the East. It would seem that some of the Egyptian temples were orientated in the direction of the sun or of some selected star, the exact position of which on some particular day would be an indication to the priest of the exact time of the year—a matter of great importance in an agricultural country, when the calendar was unknown. The orientation of Greek temples has enabled astronomers to calculate the dates of the foundation of early temples, allowance being made for the gradual change which in the course of centuries had taken place in the precession of the equinox. The principal front of the Greek temple always faced east; and the rays of the rising sun, passing through the great doorway of the naos, lighted up the statue at the further end, this being the only occasion on which the people who came to witness the event were able to gaze upon the sculptured figure of the deity.

In early Christian architecture, in the five first basilicas built by Constantine, the apse of the church was at the west end, and the priest, standing behind the altar, faced the east; this orientation being probably derived from that of the church of the Holy Sepulchre at Jerusalem and the church at Bethlehem. Three-fourths of the early churches in Rome followed this orientation, but in many it was reversed at a later date. In Sta. Sophia, Constantinople, and all the Byzantine churches, the apse was always at the east end, and the same custom obtained in the early churches in Syria and the Coptic churches in Egypt.

In Spain, Germany and England generally the eastern
